Log on to the Command Line Interface by using SSH 363
NetScaler GUI 365
Use the NetScaler GUI 366
Use the Statistical Utility 367
Configure the ADC for the first time 367
NITRO API 367
Secure your NetScaler deployment 368
Configure high availability 368
Add a Node 370
Through CLI 371
Through GUI 371
Disable high availability monitoring for unused interfaces 372
Through CLI 372
Through GUI 373
Change an RPC node password 374
To change an RPC node password by using the GUI 375
To change an RPC node password by using the CLI 376
Configure a FIPS appliance for the first time 377
Configure secure HTTPS by using the CLI 378
Configure secure HTTPS by using the GUI 378
Configure secure RPC by using the CLI 379
Configure secure RPC by using the GUI 380
Common network topologies 381
Set up a common two-arm topology 381
Set up a simple two-arm multiple subnet topology 381
Set up a simple two-arm transparent topology 383
Set up common one-arm topologies 384
Set up a simple one-arm single subnet topology 384

Set up a simple one-arm multiple subnet topology 385
System management settings 386
System settings 386
Packet forwarding modes 388
Enable and disable layer 2 mode 389
To enable or disable Layer 2 mode by using the CLI 390
Enable and disable layer 3 mode 391
Enable or disable Layer 3 mode by using the CLI 392
Enable or disable Layer 3 mode by using the GUI 393
Enable and disable MAC-based forwarding mode 394
Enable or disable MAC-based forwarding by using the CLI 395
Network interfaces 397
Virtual LANs 397
Link aggregate channels 398
Clock synchronization 399
DNS configuration 400
Add a name server by using the CLI 400
Add a name server by using the GUI 401
SNMP configuration 401
Add SNMP managers 402
Add SNMP traps listeners 403
To add an SNMP trap listener by using the CLI 404
To add an SNMP trap listener by using the GUI 404
Configure SNMP alarms 405
To enable or disable an alarm by using the CLI 405
To set the severity of the alarm by using the CLI 405
To configure alarms by using the GUI 406
Verify configuration 406

Configuration checklist 406
Topology configuration checklist 407
Server configuration checklist 407
Software features configuration checklist 408
Access checklist 409
Firewall checklist 409
Load balance traffic on a NetScaler appliance 409
Load balancing 411
Enable load balancing 413
To enable load balancing by using the CLI 413
To enable load balancing by using the GUI 414
Configure services and a virtual server 414
To implement the initial load balancing configuration by using the CLI 414
To implement the initial load balancing configuration by using the GUI 415
Persistence settings 415
Configure persistence based on cookies 417
To change the HTTP cookie version by using the CLI 419
To change the HTTP cookie version by using the GUI 419
To configure persistence based on cookies by using the CLI 419
To configure persistence based on cookies by using the GUI 420
Configure persistence based on server IDs in URLs 420
To configure persistence based on server IDs in URLs by using the CLI 421
To configure persistence based on server IDs in URLs by using the GUI 422
Configure features to protect the load balancing configuration 422
Configure URL redirection 423
To configure a virtual server to redirect client requests to a URL by using the CLI 423
To configure a virtual server to redirect client requests to a URL by using the GUI 424
Configure backup virtual servers 424

To configure a backup virtual server by using the CLI 425

To set up a backup virtual server by using the GUI 426

A typical load balancing scenario 426

Use case: How to force Secure and HttpOnly cookie options for websites using the NetScaler appliance 430

To configure the NetScaler appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using CLI 430

To configure the NetScaler appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using GUI 431

Accelerate load balanced traffic by using compression 432

Compression configuration task sequence 433

Enable compression 434

To enable compression by using the CLI 434

To enable compression by using the GUI 436

Configure services to compress data 436

To enable compression on a service by using the CLI 436

To enable compression on a service by using the GUI 440

Bind a compression policy to a virtual server 440

To bind or unbind a compression policy to a virtual server by using the command line 441

To bind or unbind a compression policy to a load balancing virtual server by using the GUI 443

Secure load balanced traffic by using SSL 443

SSL configuration task sequence 444

Enable SSL offload 446

Enable SSL by using the CLI 446

Enable SSL by using the GUI 447

Create HTTP services 448

Add an HTTP service by using the CLI 448

Add an HTTP service by using the GUI 452

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add an SSL based virtual server 452
Add an SSL-based virtual server by using the CLI 452
Add an SSL-based virtual server by using the GUI 455
Bind services to the SSL virtual server 455
Bind a service to a virtual server by using the CLI 455
Bind a service to a virtual server by using the GUI 458
Add a certificate-key pair 458
Add a certificate key pair by using the CLI 459
Add a certificate key pair by using the GUI 461
Bind an SSL certificate key pair to the virtual server 461
Bind an SSL certificate key pair to a virtual server by using the CLI 462
Bind an SSL certificate key pair to a virtual server by using the GUI 465
Configure support for Outlook web access 465
Create an SSL action to enable OWA support 465
Create an SSL action to enable OWA support by using the CLI 466
Create an SSL action to enable OWA support by using the GUI 467
Create SSL policies 467
Create an SSL policy by using the CLI 467
Create an SSL policy by using the GUI 468
Bind the SSL policy to the SSL virtual server 469
Bind an SSL policy to an SSL virtual server by using the CLI 469
Bind an SSL policy to an SSL virtual server by using the GUI 471
Features at a glance 472
Application switching and traffic management features 472
SSL Offloading 472
Access Control Lists 472
Load Balancing 473

LAS for NetScaler 563

Prerequisites 564

LAS supported NetScaler license types and deployments 565

FAQ 566

Are there any NetScaler licenses that the LAS does not support, and what is the path forward for those licenses? 566

Is MPX/SDX 14000 FIPS supported in LAS? 567

Are End-of-Life (EOL) NetScaler hardware units supported by LAS? 569

I am using Admin Partitions on NetScaler. Will the transition to LAS impact my deployment? 570

If I have transitioned from legacy file-based licensing to LAS-based licensing but still have legacy file-based licenses on my NetScaler or NetScaler Console, will this configuration cause a conflict? 570

© 1997–2026 Citrix Systems, Inc. All rights reserved.

I am using LAS with NetScaler Console on-prem Cloud Connect. What notification support is available for this deployment? 571

Are there any known issues with LAS exception of type license file extension? 571

In case of LAS with Pooled or Flexed license type, what is a valid bandwidth to checkout/allocate to a NetScaler instance? Is there any known issue that I must be aware of? 572

If my NetScaler is LAS licensed using Pooled/Flexed license type with Console on-premises and I want to change the license server from one Console on-premises to another (or from Console on-premises to Console service), how can I do it? 573

License Activation Service 574

Logging HTTP Header Information 791

To create an HTTP header log profile by using the the CLI 791

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind an HTTP header log profile to an LSN group by using the the CLI 792
Example 792
Logging MSISDN Information 794
Perform the following tasks for including MSISDN information in LSN logs 795
To create an LSN log profile by using the CLI 795
To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI 795
Displaying Current LSN Sessions 797
Configuration Using the CLI 797
To display all LSN sessions by using the CLI 797
To display selective LSN sessions by using the CLI 797
Example 798
Configuration Using the Configuration Utility 798
To display all or selected LSN sessions by using the configuration utility 798
Parameter Descriptions (of commands listed in the CLI procedure) 798
Displaying LSN Statistics 799
To display all LSN statistics by using the CLI 799
To display statistics for a specified LSN group by using the CLI 799
Example 800
Parameter Descriptions (of commands listed in the CLI procedure) 802
Compact Logging 802
Configuration Steps 803
To create an LSN log profile by using the CLI 803
To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI 804
IPFIX Logging 805
Points to Consider before you Configure IPFIX logging 805
Configuration Steps 805
To enable LSN logging in the AppFlow configuration by using the CLI 806
To create an LSN log profile by using the CLI 806

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI 806
To create an LSN log profile by using the GUI 806
To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI 806
TCP SYN Idle Timeout 807
Overriding LSN configuration with Load Balancing Configuration 808
To enable override lsn in a net profile by using the CLI 809
To enable override lsn while adding a net profile, at the command prompt, type 809
To enable override lsn while adding a net profile, at the command prompt, type 809
To enable override lsn in a net profile by using GUI 809
Clearing LSN Sessions 810
To clear all LSN sessions by using the command line interface 810
To clear selective LSN sessions by using the command line interface 810
Example 810
To clear all LSN sessions by using the configuration utility 811
Parameter Descriptions (of commands listed in the CLI procedure) 811
Load Balancing SYSLOG Servers 812
Load balancing of SYSLOG servers using the configuration utility 813
Port Control Protocol 815
Configuration Steps 815
To create a PCP profile by using the CLI 816
To create a PCP server by using the CLI 817
Sample Configuration for NAT44 817
LSN44 in a cluster setup 818
Dual-Stack Lite 821
Architecture 821
Example 823
Points to Consider before Configuring DS-Lite 826
Configuring DS-Lite 827

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration by Using the Command Line 828
Configuration by Using the Configuration Utility 831
Logging and Monitoring DS-Lite 833
Displaying Current DS-Lite Sessions 836
Configuration by Using the Command Line Interface 836
Configuration Using the Configuration Utility 837
Clearing DS-Lite Sessions 837
Configuring DS-Lite Static Maps 838
To create a DS-Lite static LSN mapping by using the command line 838
Parameter Descriptions 839
add lsn static 839
To create a DS-Lite static LSN mapping by using the configuration utility 840
Configuring Deterministic NAT Allocation for DS-Lite 840
Example: Deterministic DS-Lite 840
Configuration Steps 841
Points to Consider before Configuring Deterministic DS-Lite 841
Configuring Application Layer Gateways for DS-Lite 844
Application Layer Gateway for FTP, ICMP, and TFTP Protocols 844
Application Layer Gateway for SIP Protocol 844
Limitations of SIP ALG 845
Configuring SIP ALG 845
To enable SIP ALG for an LSN configuration by using the CLI 845
To enable SIP ALG for an LSN configuration by using the CLI 846
Sample Configuration 846
Application Layer Gateway for RTSP Protocol 847
Limitations of RTSP ALG 848
Configuring RTSP ALG 848
To enable RTSP ALG for an LSN configuration by using the CLI 849

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable RTSP ALG for an LSN configuration by using the CLI 849
Sample RTSP ALG Configuration 849
Logging and Monitoring DS-Lite 851
Displaying Current DS-Lite Sessions 854
To display all DS-Lite sessions by using the command line interface 854
To display selected DS-Lite sessions by using the command line interface 854
Configuration Using the Configuration Utility 855
Clearing DS-Lite Sessions 855
To clear all DS-Lite sessions by using the command line interface 855
To clear selected DS-Lite sessions by using the command line interface 855
To clear all or selected DS-Lite sessions by using the configuration utility 856
Logging HTTP Header Information 856
Configuration Steps 856
To create an HTTP header log profile by using the command line interface 857
To bind an HTTP header log profile to an LSN group by using the command line interface 857
Sample Configuration 857
IPFIX Logging 859
Points to Consider before you Configure IPFIX logging 860
Configuration Steps 860
To enable LSN logging in the AppFlow configuration by using the CLI 860
To create an LSN log profile by using the CLIAt the command prompt, type 860
To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI 861
To create an LSN log profile by using the GUI 861
To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI 861
Port Control Protocol for DS-Lite 861
Configuration Steps 862
To create a PCP profile by using the CLI 862
To create a PCP server by using the CLI 863

Sample Configuration for DS-LITE 863
Large Scale NAT64 864
Architecture 865
Example: Traffic Flow of NAT64 and DNS64 Deployment 866
DNS64 Traffic Flow 867
NAT64 Traffic Flow 867
Large Scale NAT64 features Supported on NetScaler appliances 869
Points to Consider for Configuring Large Scale NAT64 870
Configuring DNS64 871
To create a service of type DNS by using the command line interface 871
To create a DNS64 action by using the command line interface 871
To create a DNS64 policy by using the command line interface 872
To create a DNS load balancing virtual server by using the command line interface 872
To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the command line interface 872
Configuring Large Scaler NAT64 873
Configuration Using the Command Line 875
To create an LSN client by using the command line interface 875
To bind an IPv6 network or an ACL6 rule to an LSN client by using the command line interface 875
To create an LAN pool by using the command line interface 875
To bind NAT IP addresses to an LSN pool by using the command line interface 875
To configure an LSN IPv6 profile by using the command line interface 876
To create an LSN transport profile by using the command line interface 876
To create an LSN application profile by using the command line interface 877
To bind an application protocol port range to an LSN application profile by using the command line interface 877
To create an LSN group by using the command line interface 877

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind LSN protocol profiles and LSN pools to an LSN group by using the command line interface 878

Sample Large Scale NAT64 Configurations 878

Configuring Application Layer Gateways for Large Scale NAT64 880

Application Layer Gateway for FTP, ICMP, and TFTP Protocols 881

Application Layer Gateway for SIP Protocol 881

Limitations of SIP ALG 881

Configuring SIP ALG 882

To enable SIP ALG for an LSN configuration by using the CLI 882

To enable SIP ALG for an LSN configuration by using the CLI 883

Sample Configuration 883

Application Layer Gateway for RTSP Protocol 885

Limitations of RTSP ALG 885

Configuring RTSP ALG 885

To enable RTSP ALG for an LSN configuration by using the CLI 886

To enable RTSP ALG for an LSN configuration by using the CLI 886

Sample RTSP ALG Configuration 886

Configuring Static Large Scale NAT64 Maps 888

To create a Large Scale NAT64 mapping by using the command line 888

Wildcard Port Static Large Scale NAT64 Maps 888

Logging and Monitoring Large Scale NAT64 890

Logging Large Scale NAT64 890

Configuration Steps 892

To log large scale NAT64 information by using the CLI 892

Sample Configuration 893

Logging MSISDN Information for Large Scale NAT64 894

Configuration Steps 895

To create an LSN log profile by using the CLI 895

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind an LSN log profile to an LSN group of an NAT64 LSN configuration by using the CLI 895
Sample Configuration 896
Compact Logging for Large Scale NAT 897
Configuration Steps 897
To create an LSN log profile by using the CLI 897
To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI 897
Logging HTTP Header Information 899
Configuration Steps 899
To create an HTTP header log profile by using the the command line interface 899
To bind an HTTP header log profile to an LSN group by using the the command line interface 900
Sample Configuration 900
Displaying Current Large Scale NAT64 Sessions 901
To display all large scale NAT64 sessions by using the command line interface 901
To display selective large scale NAT64 sessions by using the command line interface 902
Displaying Large Scale NAT64 Statistics 902
To display total statistics of large scale NAT64 by using the command line interface 902
To display statistics for a specified large scale NAT64 configuration by using the command line interface 902
Clearing Large Scale NAT64 Sessions 902
To clear all large scale NAT64 sessions by using the command line interface 903
To clear selective large scale NAT64 sessions by using the command line interface 903
IPFIX Logging 904
Points to Consider before you Configure IPFIX logging 904
Configuration Steps 904
To enable LSN logging in the AppFlow configuration by using the CLI 905
To create an LSN log profile by using the CLIAt the command prompt, type 905
To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI 905
To create an LSN log profile by using the GUI 905

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI 905
Port Control Protocol for Large Scale NAT64 906
Configuration Steps 906
To create a PCP profile by using the CLI 907
To create a PCP server by using the CLI 907
Sample Configuration for NAT64 908
LSN64 in a cluster setup 909
Mapping Address and Port using Translation 911
Configuring MAP-T 912
To add a default mapping rule by using the CLI 912
To add a basic mapping rule by using the CLI 912
To bind IPv4 NAT address range of CE devices to a basic mapping rule by using the CLI 913
To add a map domain by using the CLI 913
To bind a basic mapping rule to a map domain by using the CLI 913
Sample configuration 913
Telco subscriber management 914
Allocating memory for the subscriber session store module 915
Example 916
Configure an interface for dynamic subscribers 917
Gx interface 917
To set up a Gx interface, perform the following tasks 919
Example 920
ARGUMENTS 921
vServer 921
Service 921
pcrfRealm 921
holdOnSubscriberAbsence 921
requestTimeout 921

requestRetryAttempts 922
healthCheck 922
healthCheckTTL 922
cerRequestTimeout 922
revalidationTimeout 922
negativeTTL 923
negativeTTLLimitedSuccess 923
purgeSDBonGxFailure 923
servicePathAVP 923
servicePathVendorid 923
To configure Gx interface by using the GUI 923
Detect transport failures over established Gx connections 924
To detect transport failures over established Gx connections by using the CLI 924
To detect transport failures over established Gx connections by using the GUI 925
Gx interface in a cluster topology 925
To configure the diameter parameters by using the GUI 926
To configure the diameter parameters by using the CLI 926
ARGUMENTS 926
Identity 927
OwnerNode 927
To configure a Gx interface for cluster deployment 927
RADIUS interface 929
ARGUMENTS 930
ListeningService 930
svrState 930
To configure RadiusOnly interface by using the GUI 931
RADIUS and Gx interface 931
To configure RadiusAndGx interface by using the GUI 932

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure static subscribers 933
Default subscriber profile 934
View and clear subscriber sessions 934
Subscriber policy enforcement & management system 936
IPv6 prefix based subscriber sessions 937
To configure the IPv6 prefix by using the command line 938
To configure the IPv6 prefix by using the configuration utility 938
IP address and VLAN ID key lookup method 938
To configure IP or IPANDVLAN as the key lookup method by using the CLI 939
VLAN parameter 939
Arguments 940
ip 940
vlan 940
To configure IP or IPANDVLAN as the key lookup method by using the GUI 941
Idle session management of subscriber sessions in a Telco network 941
To configure the idle session timeout and the associated action by using the command line 941
To configure the idle session timeout and the associated action by using the configuration utility 942
Subscriber session event logging 942
Subscriber aware LSN session termination 943
To configure subscriber aware LSN session termination by using the CLI 944
To configure subscriber aware LSN session termination by using the GUI 944
Troubleshooting 945
Subscriber aware traffic steering 945
To configure traffic steering for the above deployment by using the CLI 946
To configure traffic steering on the appliance by using the GUI 952
To configure service chaining on the appliance by using the GUI 953
Subscriber aware service chaining 954
To configure service chaining for the above deployment by using the CLI 955

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure service chaining on the appliance by using the GUI 964

Subscriber aware traffic steering with TCP optimization 965

Policy based TCP profile selection 971

Load Balance Control-Plane Traffic that is based on Diameter, SIP, and SMPP Protocols 973

SIP 973

SMPP 973

Diameter 974

Provide DNS Infrastructure/Traffic Services, such as, Load Balancing, Caching, and Logging for Telecom Service Providers 974

Provide Subscriber Load Distribution Using GSLB Across Core-Networks of a Telecom Service Provider 975

Bandwidth Utilization Using Cache Redirection Functionality 976

NetScaler Video Optimization 1034

Getting Started 1034

How NetScaler Video Optimization Works 1035

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Benefits 1035
Video Optimization over TCP 1036
Dynamic Burst Control 1037
Random Sampling 1037
Video Optimization over UDP 1038
Licensing 1038
Configuring Video Optimization over TCP 1040
Configuring Video Optimization over TCP by using the CLI 1040
Enabling Video Optimization 1040
To enable the video optimization feature 1040
Creating Virtual Servers for HTTP and HTTPS Video Traffic 1041
To add an HTTP Load Balancing virtual server for detecting HTTP video traffic 1041
To add an SSL Bridge virtual server for detecting HTTPS video traffic 1041
Binding Built-In Detection Policies to an HTTP Load Balancing Virtual Server 1042
To bind detection policies for different video types to an HTTP load balancing virtual server 1042
Binding the HTTP Body Content Detection Policy to Load Balancing Virtual Server 1044
Binding Built-In Detection Policies to an SSL-Bridge Load Balancing Virtual Server 1044
To bind a detection policy to an SSL bridge load balancing virtual server 1044
Adding Optimization Policies for Pacing ABR traffic 1045
To add an optimization action 1045
To add an optimization policy 1046
Binding Optimization Policies to an HTTP Load Balancing Virtual Server 1046
To bind an optimization policy to a Load Balancing virtual server 1046
Binding Optimization Policies to SSL-bridge Virtual Servers 1046
To bind an optimization policy to SSL Bridge virtual server for pacing encrypted traffic 1047
Setting video optimization pacing parameters 1047
To set the random sampling percentage 1047
Configuring Video Optimization over TCP by using the GUI 1047

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable video optimization feature 1048
To create load balancing virtual server for HTTP traffic 1048
To create load balancing virtual server for HTTPS traffic 1048
To bind a built-in detection policy to a load balancing virtual server 1049
To bind a built-in detection policy to a SSL-bridge load balancing virtual server 1049
To create a video optimization action 1050
To create a video optimization policy 1050
To set video optimization pacing parameters 1051
To bind a video optimization policy to an HTTP load balancing virtual server 1051
To bind a video optimization policy to an SSL-bridge load balancing virtual server 1051
Configuring Video Optimization over UDP 1052
Configuring video optimization for QUIC by using the CLI 1052
Enabling video optimization for QUIC traffic 1053
To enable the video optimization 1053
Creating a service for QUIC traffic 1053
To create a load balancing web service for QUIC video traffic 1053
Creating a load balancing virtual server for QUIC traffic 1054
To create a load balancing virtual server for QUIC video traffic 1054
Binding a QUIC web service to the load balancing virtual server 1054
To bind a web service to load balancing virtual server for QUIC video traffic 1054
Creating Video Optimization Policy for QUIC based UDP traffic 1054
To add an optimization action 1054
To add an optimization policy 1055
Binding Optimization Policies to a QUIC Load Balancing Virtual Server 1055
To bind an optimization policy to a QUIC Load Balancing virtual server 1055
Configuring video optimization for QUIC by using the GUI 1056
To enable video optimization 1056
To create a QUIC servers 1056

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create a QUIC service 1057
To create a load balancing virtual server 1057
To bind a load balancing virtual server to a QUIC service 1058
To bind a load balancing virtual server to a QUIC service 1058
To create a video optimization action for QUIC traffic 1058
To create a video optimization policy for QUIC traffic 1059
To bind a video optimization policy to an QUIC load balancing virtual server 1059
NetScaler URL Filtering 1060
URL List 1060
URL List Types 1060
URL List Policy Expressions 1061
URL List Policy Actions 1062
Prerequisites 1062
DNS Server for DNS Requests 1062
Importing a custom URL list 1063
Configuring a URL List for HTTP traffic 1063
To add a URL list action 1063
To add a HTTP load balancing virtual server for HTTP traffic 1063
To bind URL list policy to HTTP load balancing virtual server 1063
Configuring URL List for HTTPS traffic 1064
To add a URL List policy for HTTPS traffic 1064
To add a SSL-bridge load balancing virtual server 1064
To bind URL List policy with SSL-bridge load balancing by using the CLI 1064
Configuring a URL List by using the GUI 1065
To import a URL list 1065
To add a URL list 1065
To configure a URL list action 1066
To configure a URL list policy 1066

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To add an HTTP load balancing virtual server 1067
To bind a URL List policy to the HTTP load balancing virtual server 1067
To add URL List policy for HTTPS traffic 1067
To add a SSL-bridge load balancing virtual server for HTTPS traffic 1068
To bind a URL List Policy to the SSL-bridge load balancing virtual server 1068
Configuring Audit Log Messaging 1069
URL List Semantics 1069
URL Categorization 1070
How URL Categorization Works 1071
Prerequisites 1072
URL Categorization Policy Expressions 1073
Sample Policy Expressions 1074
URL Categorization Policy Actions 1074
Configuring URL Categorization 1075
Setting up URL Categorization 1076
To enable URL Filtering feature 1076
To configure shared memory limit 1076
To configure URL categorization parameters 1076
Configuring URL categorization for HTTP traffic 1077
To add URL categorization action for HTTP traffic 1077
To add URL categorization policy for HTTP traffic 1077
To add an HTTP load balancing virtual server 1077
To bind URL categorization policy with load balancing virtual server 1078
Configuring URL categorization for HTTPS traffic 1078
To add URL categorization policy for HTTPS traffic 1078
To add SSL-Bridge load balancing virtual server 1078
To bind categorization policy with SSL-Bridge virtual server 1079
Configuring URL Categorization by using the GUI 1079

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable URL categorization 1079
To add a URL categorization action 1079
To add a URL categorization policy for HTTP traffic 1080
To add a categorization policy for HTTPS traffic 1080
To add a load balancing virtual server for HTTP traffic 1081
To add an SSL-bridge load balancing virtual server 1081
To bind a URL categorization policy to the HTTP load balancing virtual server 1082
To bind a categorization policy to the SSL-bridge load balancing virtual server 1082
To configure the shared memory limit 1082
To configure URL categorization parameters 1083
Configuring Audit Log Messaging 1083
Storing Failure Errors Using SYSLOG Messaging 1084
URL Reputation Score 1084
FAQs 1086
This section provides the FAQ on the following NetScaler features 1086
Authentication, Authorization, and Auditing 1086
Web Application Firewall protection 1086
Admin Partition 1087
Where can I get the NetScaler configuration file for a partition? 1087
How can I configure integrated caching in a partitioned NetScaler appliance? 1087
What is the scope for L2 and L3 parameters in admin partitions? 1088
How to enable dynamic routing in an admin partition? 1088
Where can I find the logs for a partition? 1089
How can I get audit logs for an admin partition? 1089
How can I get web logs for an admin partition? 1089
How can I get the trace for an admin partition? 1090
How can I get the technical support bundle specific to an admin partition? 1090

Install, upgrade, and downgrade 1117

Install and upgrade 1117

How to download a specific NetScaler release build package? 1117

How to upgrade the system software of a NetScaler appliance? 1117

Where do I find the release notes for a NetScaler release build? 1117

Where do I find security updates for NetScaler appliances? 1117

What is the use of the zebos.conf file available in a NetScaler release? 1118

I want to change the SSH port (22) on the NetScaler appliance to some other port. Is it possible to change the SSH port on the appliance? 1118

The flash directory is missing from the NetScaler appliance. What procedure must I follow to mount the flash directory? 1118

© 1997–2026 Citrix Systems, Inc. All rights reserved.

I want to log on to the NetScaler appliance without entering the password. Is it possible to configure SSH on the appliance to allow that? 1119

What is the procedure to reset the NetScaler appliance BIOS? Under what circumstances must I reset the BIOS? 1120

I need to reset the NetScaler appliance to the factory defaults. What procedure must I follow? 1121

The appliance displays a message similar to the “Jun 21 12:20:18 ns /flash/ns-10.0-47.15: dc0: NIC hangs condition #663: TX 10000/10000, RX 0, HF 0” message on the console. What is the meaning of this message? 1122

After I upgraded the NetScaler release on the appliance, the appliance still displays the earlier release/build. What can be the reason? 1122

Since I upgraded the NetScaler release on the appliance, the LCD display on the front panel of the appliance displays the out of service message or does not display anything. How can I resolve this issue? 1123

I have upgraded the NetScaler release/build. However, after the upgrade process, the appliance fails to start. Can I downgrade the appliance’s software to the previous release/build? 1123

After upgrading the NetScaler release on the appliance, I accidentally deleted the kernel file from the /flash directory. As a result, I am not able to start the appliance. Is there a method for starting the appliance in this situation? 1123

After upgrading the appliance software, I am not able to log on to the appliance, and the following message appears. I tried to resolve this issue by using the password recovery procedure, but I was not successful. Have I done something incorrectly? 1124

During an upgrade of a high availability pair, the following message appears repeatedly. What can be the reason? 1125

I want to change the netmask of the NSIP address on a NetScaler appliance. Can I do so without causing an outage? 1125

I have configured a High Availability pair of NetScaler appliances. After upgrading the software release from a preview release to a final release, I noticed that some of the appliance configurations are missing. Can I retrieve the lost configurations? 1125

Can the primary appliance and secondary appliance have separate builds? 1126

Can both the appliances in a High Availability (HA) pair be upgraded at the same time? 1126

Does NetScaler support firmware upgrades in the Amazon Web Services cloud? 1126

Can I upgrade the NetScaler instance independently of the SDX version? 1126

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Can I use the FTP server to upgrade the NetScaler appliance? 1127

Is the procedure for upgrading the NetScaler appliance with GSLB configurations different from an upgrade of an appliance that is not involved in GSLB? 1127

Upgrade fails with a warning "Many deprecated features, parameters, and functionalities, and use of classic expressions have been removed". How do I fix this issue? 1127

Downgrade 1128

I have received a NetScaler appliance with the latest NetScaler release installed on it. However, I want to downgrade the software release. Can I do so? 1128

When downgrading the NetScaler release, I followed the instructions. However, the appliance displays the following message. How is the rollback procedure performed on a NetScaler appliance? 1128

SAML authentication 1275
Why use SAML authentication 1276
NetScaler as a SAML SP 1277
Configure the NetScaler appliance as a SAML SP by using the CLI 1279
Configure a NetScaler appliance as a SAML SP by using the GUI 1280
Points to note about the relaystateRule parameter 1285
Relay state rule configurations for different uses cases 1287
AAATM use case 1287
VPN use case 1289
IdP use case 1290
NetScaler as a SAML IdP 1291
Configure NetScaler as a SAML IdP by using the CLI 1292
Configure NetScaler as a SAML IdP by using the GUI 1296
Configure SAML single sign-on 1301
Configuring SAML single sign-on by using the CLI 1301
Configuring SAML single sign-on by using the GUI 1302
Configure Microsoft Entra ID as SAML IdP and NetScaler as SAML SP 1307
Microsoft Entra ID side configurations 1308
NetScaler side configurations 1310
More features supported for SAML 1314
Metadata reading and generation support for SAML SP and IdP configuration 1314
Metadata export for SAML SP 1314
Metadata import for SAML SP 1316
Metadata import for SAML IdP 1316
Name-value attribute support for SAML authentication 1317
To configure the name-value attributes by using the CLI 1317
Assertion Consumer Service URL support for SAML IdP 1317
Increase of SessionIndex size in SAML SP 1318

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Custom authentication class reference support for SAML SP 1318
To configure the customAuthnCtxClassRef attributes by using the CLI 1318
To configure the customAuthnCtxClassRef attributes by using the GUI 1319
Support for artifact binding in SAML IdP 1319
Assertion Consumer Service URL support for SAML IdP 1319
FIPS offload support 1319
Common SAML terminologies 1320
Other useful Citrix articles related to SAML authentication 1322
OAuth authentication 1322
Points to note 1322
Configure the OpenID Connect protocol 1323
Advantages of having the OpenID Connect support 1323
To configure a NetScaler appliance as an IdP using the OpenID Connect protocol by using GUI 1323
Binding the OAuthIdP policy and LDAP policy to the authentication virtual server 1324
To configure the NetScaler appliance as an IdP using the OpenID Connect protocol by using CLI 1325
NetScaler as an OAuth SP 1326
Points to note 1326
Configure OAuth by using the GUI 1326
Configure OAuth by using the CLI 1329
Name-value attribute support for OAuth authentication 1330
To configure the name-value attributes by using the CLI 1330
NetScaler as an OAuth IdP 1331
Advantages of having NetScaler as an OAuth IdP 1331
To configure NetScaler as an OAuth IdP using the GUI 1332
To configure NetScaler as an IdP using the OIDC protocol by using the CLI 1334
Encrypted tokens support on OIDC protocol 1337

Email Validation – Failure scenario 1499
re-Captcha configuration for nFactor authentication 1500
re-Captcha configuration 1501

© 1997–2026 Citrix Systems, Inc. All rights reserved.

re-Captcha configuration on Google 1501
re-Captcha configuration for Admin Console (re-Captcha v2 and v3) 1501
re-Captcha configuration for Enterprise Console (re-Captcha v3) 1503
re-Captcha configuration on NetScaler 1504
Display re-Captcha screen 1504
To configure display of re-Captcha by using the CLI 1505
Post the re-Captcha response to the Google server 1506
To verify re-Captcha response from the browser for the Admin console 1507
To verify re-Captcha response from the browser for the Enterprise console 1508
Configure LDAP as the second factor for user logon 1508
User validation of re-Captcha 1509
Web proxy support for outbound calls to IdP or third party endpoints 1512
Prerequisites 1514
Configure an outbound proxy by using the CLI 1514
Configure an outbound proxy by using the GUI 1516
Use cases 1516
Use case 1: OAuth authorization code flow with Duo universal prompt 1516
Use case 2: NetScaler Gateway and Microsoft Intune integration 1516
Single sign-on types 1517
NetScaler kerberos single sign-on 1517
An overview of NetScaler kerberos SSO 1518
Integration of NetScaler Kerberos SSO with authentication methods 1519
Set up NetScaler SSO 1520
Prerequisites for configuring NetScaler SSO 1520
To create a server and service by using the CLI 1521
To create a traffic management virtual server by using the CLI 1522
To create an authentication virtual server by using the CLI 1523
To configure a traffic management virtual server to use an authentication profile 1524

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure single sign-on 1525
Enable integrated authentication on the web application server 1525
To configure Microsoft IIS to use integrated authentication 1526
Set up SSO by impersonation 1526
To create the KCD account for SSO by impersonation with a password 1527
Example 1527
Configure custom salt expression for Kerberos impersonation in KCD accounts 1527
To configure the custom salt expression by using the CLI 1528
Key features 1528
Limitation 1528
Configure SSO by delegation 1528
Installing the client CA certificate on the NetScaler appliance 1529
To install the client CA certificate on the NetScaler appliance 1529
Creating the KCD account 1530
To create the KCD account for SSO by delegation with a password 1531
Creating the KCD account for SSO by delegation with a keytab 1532
To create the keytab file manually 1533
To use the NetScaler configuration utility to create a script to generate the keytab file 1533
To create the KCD account 1534
To create the KCD account for SSO by delegation with a delegated user cert 1534
Setting up Active Directory for NetScaler SSO 1535
To configure delegation for the Kerberos service account 1536
Configuration changes to enable KCD to support child domains 1536
Points to note when advanced encryptions are used to configure KCD account 1537
Domain user information 1537
When configuring NetScaler SSO using Kerberos delegation 1537
When configuring NetScaler SSO using Kerberos impersonation 1538
Troubleshooting KCD account configuration 1538

Rewrite for NetScaler Gateway and authentication server generated responses 1553

An example to use Rewrite 1554

Sample configuration 1554

Content Security Policy response header support for NetScaler Gateway and authentication virtual server-generated responses 1555

Configuring Content-Security-Policy header for NetScaler Gateway and authentication virtual server-generated responses 1555

Custom Content-Security-Policy header 1559

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Rewrite policies to support DUO authentication 1560
Rewrite policies for VPN virtual server 1560
Rewrite policies for Traffic Management (TM) virtual server 1561
Self-service password reset 1562
Prerequisites 1564
Limitations 1565
Active Directory setting 1565
Enforce SSPR registration at login 1566
Self-service password reset registration 1567
To view the default knowledge-based questions JSON file from CLI 1567
To complete knowledge-based question and answer registration Login Schema using GUI 1568
Create user registration and management workflow using CLI 1569
To create authentication virtual server 1570
To create LDAP logon action 1570
To create an authentication policy for LDAP logon 1571
To create knowledge-based question and answer registration action 1571
Display user registration and management screen 1572
Using URL 1572
To create and bind the registration policy 1572
To bind authentication policy to authentication, authorization, and auditing virtual server when the URL contains '/register' 1572
To bind certificate to VPN global 1573
Using attribute 1573
To create an authentication policy to check if the user is not already registered 1574
To create a registration policy label and bind to the LDAP registration policy 1574
To bind authentication policy to authentication, authorization, and auditing virtual server 1574
User registration and management validation 1574
Configure the user logon page 1575

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create load balancer virtual server by using CLI 1576

Create LDAP action with authentication disabled as first policy 1576

Create knowledge-based question and answer validation action 1577

To create an authentication policy for knowledge-based question and answer validation using CLI 1577

Create an email validation action 1577

To configure email action using the CLI 1579

To configure email ID using the GUI 1580

To create an authentication policy for email validation by using CLI 1580

To create an authentication policy for the password reset factor 1580

Presenting UI through Login Schema 1580

To create single authentication password reset by using CLI 1581

Create knowledge-based question and answer and email OTP validation factor through the policy label 1581

Create password reset factor through the policy label 1581

Bind the flow 1582

To bind all the UI flow 1582

User log on workflow to reset password 1583

Troubleshooting 1583

NS Log 1583

Registration 1584

Knowledge-based question and answer validation 1584

Email ID validation 1584

Configure SSPR using nFactor visualizer 1584

Now that the LDAP servers are added, proceed with the nFactor configuration using the visualizer 1585

User Registration 1586

Password reset 1587

To create a traffic policy by using the command line interface 1623

To modify a traffic policy by using the command line interface 1623

To globally bind a traffic policy by using the command line interface 1623

To bind a traffic policy to a load balancing or content switching virtual server by using the command line interface 1624

To unbind a globally bound traffic policy by using the command line interface 1624

To unbind a traffic policy from a load balancing or content switching virtual server by using the command line interface 1624

To remove a traffic policy by using the command line interface 1625

To configure and bind traffic policies by using the configuration utility 1625

Form SSO profiles 1626

To create a form SSO profile by using the command line interface 1626

To modify a form SSO by using the command line interface 1627

To remove a form SSO profile by using the command line interface 1627

To configure form SSO profiles by using the configuration utility 1628

SAML SSO profiles 1628

To create a SAML SSO profile by using the command line interface 1628

To modify a SAML SSO by using the command line interface 1629

To remove a SAML SSO profile by using the command line interface 1629

To configure a SAML SSO profile by using the configuration utility 1630

Session timeout for OWA 2010 1630

To force OWA 2010 to time out after a specified period by using the command line interface 1630

Rate Limiting for NetScaler Gateway 1631

Common use-cases for Rate limiting 1632

Configure Rate Limiting for NetScaler Gateway 1632

Prerequisites 1632

Points to note 1632

Parameter description 1633

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration for the common use cases for applying rate limiting to NetScaler Gateway 1636
Bind responder policy for authentication, authorization, and auditing endpoints 1639
Troubleshooting responder action configuration 1639
Client source IP address tracking 1641
Configure client source IP address tracking for sessions 1642
Client IP address validation using X-Forwarded-For (XFF) in AAA sessions 1642
Benefits 1643
Prerequisites 1643
How it works 1643
Key policy expressions 1643
Configuration examples 1643
Limitations 1644
Authorizing user access to application resources 1645
To configure authorization by using the CLI 1645
To configure authorization by using the GUI (Configuration tab) 1646
Sample authorization configurations 1646
Audit authenticated sessions 1646
To configure syslog auditing by using the CLI 1647
To configure syslog auditing by using the GUI 1647
NetScaler as an Active Directory Federation Services proxy 1648
Advantages of ADFS proxy 1649
Prerequisites for using NetScaler as ADFS proxy 1649
Configure NetScaler appliance as ADFS proxy 1649
Configure NetScaler appliance as ADFS proxy using the CLI 1650
To configure ADFS service 1650
To configure ADFS load balancing virtual server 1651
To configure content switching virtual server for domain 1652
Supported protocols 1652

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Web Services Federation protocol 1653

Advantages of WS-Federation 1653

Prerequisites for using NetScaler as WS-Federation 1653

Features supported by NetScaler when configured as ADFS proxy and WS-Federation IdP 1654

Configure NetScaler appliance as WS-Federation IdP 1655

Configure NetScaler appliance as WS-Federation IdP (SAML IdP) using the CLI 1655

To configure LDAP authentication and add policy 1656

To configure NetScaler as WS-Federation IdP or SAML IdP 1657

To configure an authentication, authorization, and auditing virtual server to authenticate the employees who log on to Office365 using corporate credentials 1657

To bind authentication virtual server and policy 1658

To configure content switching 1658

To bind content switching virtual server to policy 1659

Active Directory Federation Service Proxy Integration Protocol compliance 1659

Prerequisites 1660

Authentication mechanism 1660

Configure NetScaler to support ADFS server 1661

Prerequisites 1661

Create an SSL certificate with private key to use with ADFS proxy profile by using the GUI 1663

Create an SSL certificate with private key to use with ADFS proxy profile by using the CLI 1664

Create an ADFS proxy profile using the GUI 1664

Create an ADFS proxy profile using the CLI 1665

Associate the ADFS proxy profile to the load balancing virtual server using the GUI 1666

Associate the ADFS proxy profile to the load balancing virtual server using the CLI 1667

Trust renewal support for ADFSPIP 1667

To configure the trust renewal of certificates by using the CLI 1668

Client certificate based authentication on ADFS server 1668

Configure SSO for ADFS server using client certificate 1669

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use an on-premises NetScaler Gateway as the identity provider for Citrix Cloud 1671
Prerequisites 1671
Create an OAuth IdP policy on the on-premises NetScaler Gateway 1672
Creating an OAuth IdP profile by using the CLI 1672
Creating an OAuth IdP profile by using the GUI 1673
Binding the OAuthIDP policy and LDAP policy to the authentication virtual server 1676
Store Authentication Context Class Reference values 1677
Support for active-active GSLB deployments on NetScaler Gateway 1678
GSLB active-active support for multifactor authentication using connection proxy 1678
How it works 1678
Configuration support for SameSite cookie attribute 1679
Configure SameSite cookie attribute 1679
Setting the SameSite attribute by using the CLI 1680
Binding cookies to the patset by using the CLI 1680
Setting the SameSite attribute by using the GUI 1680
Authentication, authorization, and auditing configuration for commonly used protocols 1682
Handling authentication, authorization and auditing with Kerberos/NTLM 1682
Optimizing Kerberos authentication on authentication, authorization, and auditing 1684
How NetScaler implements Kerberos for client authentication 1684
Key Distribution Center (KDC) 1684
Authentication service and protocol negotiation 1684
Authorization 1685
Auditing 1685
Supported Environment 1685
High Availability 1685
Kerberos authentication process 1686
Client authenticates itself to the KDC 1686
Configuring kerberos authentication on the NetScaler appliance 1687

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring Kerberos authentication on the CLI 1687
Configuring Kerberos authentication on the GUI 1690
Configure kerberos authentication on a client 1691
To configure Internet Explorer for Kerberos authentication 1691
To configure Mozilla Firefox for Kerberos authentication 1691
Offload Kerberos authentication from physical servers 1692
To configure Kerberos authentication on the NetScaler appliance 1692
To configure Internet Explorer for Kerberos authentication 1694
To configure Mozilla Firefox for Kerberos authentication 1694
Troubleshoot authentication and authorization-related issues 1695
Localize error messages 1695
Troubleshoot authentication issues with aaad.debug module 1695
Troubleshoot authentication, authorization and auditing issues 1695
Troubleshoot authentication issues in NetScaler and NetScaler Gateway with aaad.debug module 1695
Troubleshooting authentication issues 1696
Incorrect password 1697
Invalid username 1697
Determining group extraction results 1698
aaad.debug module error codes 1698
Localize error messages generated by NetScaler nFactor system 1702
Enhanced authentication feedback 1703
Configure certificate authentication as the first factor and LDAP as the second factor in NetScaler nFactor authentication 1703
Use Case: Certificate authentication as the first factor followed by LDAP as the next factor 1704
Perform the following by using the CLI 1706
Configuring by using the nFactor Visualizer 1709
Unbind the nFactor flow 1717

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure domain drop-down, username, and password field in the first factor and policy evaluation based on groups in the next factor 1718

Configure domain drop-down, username, and password field in the first factor and policy evaluation based on groups in the next factor using nFactor visualizer 1719

Configure domain drop-down, username, and password field in the first factor and policy evaluation based on groups in the next factor using CLI 1727

Configure EULA as an authentication factor in NetScaler nFactor system 1729

nFactor flow presentation 1729

Configuration by using the CLI 1730

Configuration by using the nFactor Visualizer 1731

To unbind the nFactor flow 1737

Login schema used in this example 1738

Configure nFactor for applications with different login site requirements including step-up authentication 1739

Prerequisites 1740

Basic setup 1740

Authentication level configuration 1742

nFactor configuration for multifactor authentication 1744

Multifactor authentication configuration through nFactor Visualizer 1754

Unbind the nFactor Flow 1762

Result 1763

Configure nFactor for NetScaler Gateway with WebAuth in first factor and LDAP with password change in second factor 1766

How it works 1767

Configuration by using the CLI 1768

Configuration by using the nFactor Visualizer 1775

Debugging – Logs and counters 1779

Configure periodic Endpoint Analysis scan as a factor in nFactor authentication 1780

Pre-requisites 1781

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Perform the following by using the CLI 1782

Configuration by using the nFactor Visualizer in the GUI 1783

Configure post-authentication Endpoint Analysis scan as a factor in NetScaler nFactor authentication 1787

Prerequisites 1788

Perform the following by using the CLI 1789

Configuring using the nFactor Visualizer 1790

Configure pre-authentication Endpoint Analysis scan as a factor in nFactor authentication 1794

Prerequisites 1795

Perform the following by using the CLI 1796

Configuration by using the nFactor Visualizer 1798

Unbind the nFactor flow 1804

Configure pre-auth and post-auth EPA scan as a factor in nFactor authentication 1804

High level steps involved in this configuration 1804

Pre-requisites 1805

Configuration by using the CLI 1805

Configuration by using the GUI 1807

Unbind the nFactor flow 1815

Configure prefill user name from certificate in NetScaler nFactor authentication 1815

Use Case: Certificate and LDAP authentication 1815

Perform the following by using the CLI 1816

Configuring by using the nFactor Visualizer 1817

Unbind the nFactor Flow 1821

Configure protected user as an authentication factor in NetScaler nFactor authentication 1821

Sample configuration 1822

Configure SAML followed by LDAP or certificate authentication based on SAML attribute extraction in nFactor authentication 1824

SAML authentication in first factor with attribute extraction from SAML assertion 1824

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Perform the following by using the CLI 1827

Configuring by using the nFactor Visualizer 1828

Unbind the nFactor Flow 1835

Configure two-factor authentication with one login schema and one passthrough schema in NetScaler nFactor authentication 1835

Two-factor authentication with one login schema and one passthrough schema 1836

Perform the following by using the CLI 1836

Configuring by using the nFactor Visualizer 1838

Configure user name and two passwords with group extraction in third factor by nFactor authentication 1841

User name and two passwords with group extraction in third factor 1841

Perform the following by using the CLI 1843

Configuring by using the nFactor Visualizer 1845

Configure a domain drop-down list for user input in the first factor to decide the next factor authentication flow 1849

Configure domain drop-down list for user input in the first factor to decide the next factor authentication flow using CLI 1850

Prerequisite 1850

Configure authentication virtual server for the domain drop-down list value 1850

Create first factor as NO_AUTHN 1850

Create next factor for Employee, Partner, Vendor Departments/Division using policy labels 1851

Create a single authentication policy factor (LDAP is used as an example for this configuration) 1851

Create OAuth policy for redirecting to OAuth IdP 1852

Create SAML policy for redirecting to SAML IdP 1853

Bind the three policy factors created previously to plabel_noauth_Employee_Partner_Vendo 1853

Bind group based policy label as nextFactor for drop-down list based authentication policy selection 1854

Configure domain drop-down list for user input in first factor to decide the next factor authentication flow using GUI 1854

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Unbind the nFactor flow 1858

Configure email ID (or user name) input based group extraction at first factor to decide the next factor authentication flow 1858

Configure email ID (or user name) input based group extraction at first factor to decide the next factor authentication using CLI 1860

Prerequisite 1860

Configure authentication virtual server for email based group extraction 1860

Create login schema policy using email login schema created in the previous step and bind to the authentication virtual server 1860

Create an LDAP authentication policy for group extraction 1861

Extracted group based policy configuration 1861

Create next factor for Employee, Partner, Vendor Groups using policy labels 1861

Create a single Auth policy factor (LDAP is used as an example for this configuration) 1862

Create OAuth Policy for redirecting to OAuth IdP 1863

Create SAML Policy for redirecting to SAML IdP 1863

Bind all three policy factors to plabel_noauth_Employee_Partner_Vendor 1864

Bind group based policy label as nextFactor for group extraction authentication policy 1864

Configure email ID (or user name) input based group extraction at first factor to decide the next factor authentication by using the nFactor Visualizer 1864

Unbind the nFactor 1872

Localize error messages generated by NetScaler nFactor system 1872

Enhanced authentication feedback 1873

Configure NetScaler Gateway preauthentication EPA scan for the domain check 1873

Preauthentication EPA scan configuration by using the advanced authentication policy 1874

High level steps involved in this configuration 1874

Pre-requisites 1874

Configuration by using the GUI 1874

Configuration by using the CLI 1876

Preauthentication EPA scan configuration by using the classic authentication policy 1876

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration by using the GUI 1876
Configuration by using the CLI 1879
Admin partition 1880
User access and roles 1882
Points to remember 1882
Use case for managing role based access in a partitioned setup 1883
Configure roles and responsibilities for partition administrators 1884
Benefits of using admin partitions 1886
User case 1: How admin partition is used in an enterprise network 1886
Use case 2: How an admin partition is used by a service provider 1887
NetScaler configurations support in admin partition 1888
Case 1 (global configurations) 1888
Case 2 (partition-specific configurations) 1889
Case 3 1889
Configure admin partitions 1895
Tip 1896
Partition resource limiting 1896
Configure an admin partition 1898
Access in an admin partition by using the CLI 1898
To access an admin partition by using the GUI 1898
Add an admin partition 1899
To create an administrative partition by using the CLI 1899
Switch user access from the default partition to an admin partition 1899
Add SNIP address to a partition user account with management access enabled 1899
Create and Bind a partition user with partition command policy 1900
Create and bind partition user group with partition command policy 1900
Configuring external server authentication for external users 1900
Configure a partition system user account in a partition by using the GUI 1901

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a partition user account in a partition by using the GUI 1901
Create a partition user group account in a partition by using the GUI 1901
Configure external server authentication for external users by using the GUI 1901
Sample configuration 1902
Command policies for a partition users and partition user groups in an administrative partition 1902
Configure an LACP Ethernet channel on the default admin partition 1903
Configure and verify LACP 1904
Configure and verify LACP on NetScaler by using the CLI 1904
Save the configuration of all admin partitions from the default partition 1905
Save all admin partitions from the default partition by using the CLI 1905
Support for partition and cluster based custom reports 1906
View the custom reports of the current partition or cluster in the GUI 1906
Support to bind VPN global certificates in a partitioned setup for OAuth IdP 1906
Bind the certificates in Partitioned setup by using the CLI 1906
VLAN configuration for admin partitions 1906
Dedicated VLANs 1907
Configure the following by using the CLI 1908
Configure a dedicated VLAN by using the NetScaler GUI 1909
Shared VLAN 1909
Configure a shared VLAN by using the CLI 1910
Bind a partition to a Shared VLAN by using the CLI 1911
Configure a Partition MAC Address by using the CLI 1911
Bind partitions to a shared VLAN by using the CLI 1912
Configure Shared VLAN by using the NetScaler GUI 1912
Dynamic routing over a shared VLAN across admin partitions 1912
Before you begin 1914
Configuration steps 1914
Sample configuration 1915

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Dynamic routing of IPv6 over a shared VLAN across admin partition 1916
Sample configuration 1916
Shared VLAN with admin partition on NetScaler SDX appliance 1918
VXLAN support for admin partitions 1918
Points to remember before configuring a VXLAN 1919
Supportable VXLAN configurations 1919
Extending VLAN over a VXLAN in the same broadcast domain 1919
SNMP support for admin partitions 1920
SNMP traps for admin partition rate limiting 1921
Configuring PARTITION-RATE-LIMIT alarm 1921
To enable PARTITION-RATE-LIMIT alarm by using the CLI 1922
To configure PARTITION-RATE-LIMIT Alarm by using the CLI 1922
To configure the SNMP trap destination by using the CLI 1922
To configure the PARTITION-Rate-Limit alarm by using the GUI 1922
To configure the SNMP trap destination by using the GUI 1923
SNMP monitoring for partition resource utilization 1923
Audit log support for admin partitions 1924
Points to remember 1924
Configuring audit logging in partitioned NetScaler appliance 1924
Configure the following by using the CLI 1924
Example 1925
Storing logs 1926
Display configured PMAC addresses for shared VLAN configuration 1926
Display PMACs by using the NetScaler CLI 1927
Display PMAC Addresses by using the NetScaler GUI 1927
AppExpert 1928
Action analytics 1929
Configure a selector 1930

How other resources category works 1977
Entity naming conventions 1977
Add intranet subnets 1977
Add other resources 1978
Configure authorization policies 1979
Configure traffic policies 1979
Configure clientless access policies 1980
Configure TCP compression policies 1981
Configure bookmarks 1982
AppQoE 1982
Enable AppQoE 1983
To enable AppQoE by using the command line 1983
To enable AppQoE by using the GUI 1984
AppQoE actions 1984
To configure an AppQoE action by using the command line 1985
To modify an existing AppQoE action by using the command line 1986
To remove an AppQoE action by using the command line 1987
Parameters for configuring an AppQoE action 1987
Limitations 1989
To configure an AppQoE action by using the configuration utility 1989
AppQoE parameters 1990
To configure the AppQoE parameter settings by using the command line 1990
Parameters for configuring the AppQoE parameters 1990
To configure the AppQoE parameter settings by using the GUI 1990
AppQoE policies 1991
To configure an AppQoE policy by using the command line 1991
Parameters for configuring an AppQoE policy 1992
To configure an AppQoE policy by using the configuration utility 1992

Configure advanced policy expression: Getting started 2157
Basic elements of an advanced policy expression 2158
Prefixes 2159
Single-element expressions 2161
Operations 2162
Basic operations on expression prefixes 2162
Compound advanced policy expressions 2164
Booleans in compound expressions 2164
Parentheses in compound expressions 2165
Compound operations for strings 2166
Compound operations for numbers 2168
Functions for data types in the policy infrastructure 2171
Arithmetic Operators, Logical Operators, and Type Promotion 2172
Specify the character set in expressions 2173
Compound expressions with different character sets 2173
Specify the character set based on the character set of traffic 2174
Character and string literals in expressions 2174
Values in hexadecimal and octal formats 2175
Functions that return UTF-8 strings 2175
Terminal connection settings for UTF-8 2176
Minimum and maximum functions in an advanced policy expression 2176
Configure advanced policy expressions in a policy 2176
Configure an Advanced policy syntax rule by using the CLI 2177
Configure a Advanced policy expression by using the GUI 2178
Test a Advanced policy expression by using the GUI 2179
Configure named advanced policy expressions 2179
Example 1: Simple Named Expression as a Prefix 2180
Example 2: Compound named expression as a prefix 2180

Encrypt and decrypt text 2196
Configure encryption 2197
Configure encryption by using the GUI 2197
Use the ENCRYPT and DECRYPT functions 2197
Configure encryption key for third-party encryption 2198
Cipher methods 2199
Stream ciphers 2199
Block ciphers 2199
Padding 2200
Modes of operation 2200
Configure encryption keys for third-party encryption 2201
Add an encryption key by using the CLI 2201
Modify an encryption key by using the CLI 2202
Unset an encryption key by using the CLI 2202
Remove an encryption key by using the CLI 2202
Show an encryption key by using the CLI 2202
Add an encryption key by using the GUI 2203
Modify an encryption key by using the GUI 2203
Remove an encryption key by using the GUI 2203
ENCRYPT and DECRYPT functions for third-party encryption 2203
Variants and optional parameters 2205
Configure HMAC keys 2205
Configure a unique and random HMAC key 2206
Modify an HMAC key by using the CLI 2207
Unset an HMAC key by using the CLI 2207
Remove an HMAC key by using the CLI 2207
Show an HMAC key by using the CLI 2208
Advanced policy expressions: Working with dates, times, and numbers 2208

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Format of dates and times in an expression 2209
Expressions for the NetScaler system time 2210
Expressions for SSL certificate dates 2215
Expressions for HTTP request and response dates 2225
Generate the day of the week, as a string, in short and long formats 2225
Expression prefixes for numeric data other than date and time 2226
Convert numbers to text 2227
Virtual server based expressions 2228
Advanced policy expressions: Parsing HTTP, TCP, and UDP data 2230
About evaluating HTTP and TCP payload 2230
Expressions for identifying the protocol in an incoming IP packet 2232
Arguments to the PROTOCOL function 2232
Use case scenarios 2233
Expressions for HTTP and cache-control headers 2234
Prefixes for HTTP headers 2234
Operations for HTTP headers 2234
Prefixes for cache-control headers 2234
Operations for cache-control headers 2234
Expressions for extracting segments of URLs 2237
Expressions for HTTP status codes and numeric HTTP payload data other than dates 2238
SIP expressions 2239
SIP reference tables 2240
SIP request expressions 2240
SIP response expressions 2250
Operations for HTTP, HTML, and XML encoding and "safe" characters 2251
Expressions for TCP, UDP, and VLAN data 2254
Expressions for evaluating a DNS message and identifying its carrier protocol 2259
XPath and HTML, XML, or JSON expressions 2261

Configuring a String Map 2500
To configure a string map by using the NetScaler GUI 2501
Example: responder policy with a redirect action 2501
To configure a string map by using the NetScaler GUI 2501
URL sets 2502
Getting started 2502
Use Case for Safe Internet Access Policies for ISPs/Telcos 2503
Advanced policy expressions for URL evaluation 2504
Configure URL set 2504
Import a URL set with meta by using the command line interface 2507
Perform explicit subdomain match for an imported URL set 2507
To show the URL set by using the command line interface 2508
To show the URL set imported by using the command line interface 2509
To show URL set <urlset_name> by using the command line interface 2509
To export a URL set by using the command line interface 2509
To add a URL set by using the command line interface 2509

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To update a URL set by using the command line interface 2509
To remove a URL set command by using the command line interface 2510
Display imported URL sets 2511
To import a URL set by using the GUI 2511
To add a URL set by using the GUI 2511
To edit a URL set by using the GUI 2511
To Update a URL set by using the GUI 2511
To Export a URL set by using the GUI 2512
URL pattern semantics 2512
URL Categories 2512
AppFlow® 2522
How AppFlow Works 2523
Flow Records 2524
Templates 2524
EIEs for webpage performance data 2526
EIEs for database information 2526
Configuring the AppFlow® feature 2527
Enabling AppFlow 2527
Enable the AppFlow feature by using the command line interface 2528
Enable the AppFlow feature by using the configuration utility 2528
Specifying a Collector 2528
Specify a collector by using the command line interface 2528
Example 2529
Specify multiple collectors by using the command line interface 2529
Specify one or more collectors by using the configuration utility 2530
Configure an AppFlow Action 2530
Configure an AppFlow action by using the command line interface 2530
Example 2530

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure an AppFlow action by using the configuration utility 2531
Configure an AppFlow Policy 2531
Configure an AppFlow policy by using the command line interface 2531
Example 2531
Configure an AppFlow policy by using the configuration utility 2532
Add an expression by using the Add Expression dialog box 2532
Bind an AppFlow Policy 2532
Globally bind an AppFlow policy by using the command line interface 2533
Example 2533
Bind an AppFlow policy to a specific virtual server by using the command line interface 2534
Example 2534
Globally bind an AppFlow policy by using the configuration utility 2534
Bind an AppFlow policy to a specific virtual server by using the configuration utility 2534
Enable AppFlow for Virtual Servers 2534
Enable AppFlow for a virtual server by using the command line interface 2535
Example 2535
Enable AppFlow for a virtual server by using the configuration utility 2535
Enable AppFlow for a Service 2535
Enable AppFlow for a service by using the command line interface 2535
Example 2536
Enable AppFlow for a service by using the configuration utility 2536
Set the AppFlow Parameters 2536
Set the AppFlow Parameters by using the command line interface 2536
Example 2537
Set the AppFlow parameters by using the configuration utility 2537
Support for subscriber ID obfuscation 2537
Configure the subscriber ID obfuscation algorithm by using the CLI 2538
Example 2538

Configure REST and gRPC API schema validation using CLI 2552
Configure REST and gRPC API schema validation using GUI 2552
Configure relaxation rule for API schema validation using CLI 2553
Configure relaxation rule for API schema validation using GUI 2554
REST API schema validation 2554
gRPC API schema validation 2554
Advanced policy expressions using API specification 2555
Advanced policy expression for API schema 2556
Expression to match traffic by HTTP method 2556
Expression to match traffic by URL 2556
Expression to match traffic by API name 2557
Access values from the API specification 2557
Access value from the repeated fields 2558
Access values from the nested objects 2558
Access value using object expression 2558
API traffic visibility using API specification validation 2559
Enable API traffic visibility with the API specification using the CLI 2559
Enable API traffic visibility without the API Specification using the CLI 2560
Enable API traffic visibility using GUI 2560
AI capabilities 2562
AI Gateway 2562
AI Gateway for Kubernetes 2562
MCP Gateway 2563
NetScaler Console MCP Server 2563
AI gateway 2564
Prerequisites 2565
Configure load balancing for AI models 2565
Points to note 2570

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Content switching-based model routing 2570
Configure spillover route request to a different language model 2572
Configure rate limiting based on token consumption 2574
Prompt management 2578
Configure a prompt template to modify the system prompt 2579
AI gateway - Observability 2580
Entity: server_svc_cfg 2580
Entity: vserver_lb 2581
Entity: vserver_cs 2581
Entity: cs_pol 2582
Web Insight records 2582
Usage tracking 2583
MCP Gateway 2587
Role of NetScaler MCP Gateway 2587
Traffic management 2587
Authentication handling 2587
Policy enforcement 2588
Rate limiting 2588
NetScaler as an MCP Gateway 2588
Understanding the MCP profile 2589
Points to note 2590
Use case 2591
Prerequisites 2591
Configure NetScaler as an MCP Gateway 2591
A. Configure a content switching gateway virtual server 2591
B. Optional response-side rewrites for authentication flows 2592
C. Use the MCP profile to reduce rewrite overhead 2594
D. Sample client configuration 2594

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Troubleshooting 2595
Routing goes to the wrong backend MCP server 2595
Backend MCP server returns session errors 2595
Authentication challenges redirect clients away from the gateway 2595
Configure persistence for MCP Gateway 2595
Configure persistence by using the CLI 2596
Validation 2596
Troubleshooting 2596
Session errors 2596
Uneven load 2596
Non-sticky behavior 2596
Monitor an MCP server 2596
What the monitor does 2596
Token handling 2597
Configure a monitor by using the CLI 2597
Parameter details 2597
Best practices 2598
Tool-based rate limiting for MCP Gateway 2598
Use cases 2598
Points to note 2599
Prerequisites 2599
Limitations 2599
Configure rate limiting by using the CLI 2599
Troubleshooting 2601
Rate limiting not triggering 2601
Per-user limit not working 2601
Unexpected responses 2601
Order issues 2602

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Server access control for MCP Gateway 2602
Important considerations 2602
Prerequisites 2602
Configure allow list and block list using the CLI 2603
Sample allow list configuration 2603
Sample block list configuration 2603
Sample default deny policy 2603
Troubleshooting 2604
Request blocked unexpectedly 2604
Unauthorized access is allowed 2604
Client errors 2604
Configure NetScaler OAuth 2.1 for MCP Gateway 2604
Key benefits 2606
Seamless client integration 2606
Centralized enterprise control 2606
Multi-resource and multi-tenant ready 2606
Standards-aligned and future-proof 2606
Points to note 2607
Prerequisites 2607
Configure OAuth by using the CLI 2608
Step 1: Configure the AAA frontend virtual server and OAuth action 2608
Step 2: Configure a load balancing virtual server acting as an MCP Gateway and offload authentication to the authentication virtual server 2608
Step 3: Update and verify an existing OAuth action to use multi-scope 2608
Sample 401 response as per RFC 9470 2609
Sample resource-specific PRM response as per RFC 9728 2609
Step 4: Verify the active configuration 2610
Configure OAuth by using the GUI 2610

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations 2611

Monitoring and troubleshooting 2611

Troubleshooting 2612

Problem: An MCP client shows authorization required but fails IdP discovery 2612

Problem: An MCP client fetches resource-specific PRM but receives a default non-resource document 2612

Problem: Scope appears as a single token instead of space-separated values 2612

Authentication for MCP Gateway 2612

Prerequisites 2613

Limitation 2613

Use cases 2614

Scenario 1: Per-user access to an MCP server using user-specific PAT or Bearer tokens 2614

Scenario 2: Service-account access using a shared (global) PAT or Bearer token for a backend MCP server 2614

Scenario 3: OAuth-only access where tokens are obtained or validated via OAuth flows 2615

Scenario 4: OAuth 2.1 frontend authentication with backend access token injection (hybrid) 2615

Troubleshooting 2616

If backend authentication fails 2616

If OAuth flows fail, verify OAuth action endpoints 2616

If clients are redirected to backend endpoints instead of gateway 2616

NetScaler Web App Firewall 2617

Highlights 2619

FAQs and Deployment Guide 2620

Q: Why is NetScaler Web App Firewall the preferred choice for securing applications? 2620

Q: What do I need to do to configure Web App Firewall? 2623

Q: How do I know what profile type to choose? 2624

Q: What is the difference between basic and advanced profiles? How do I decide which one I need? 2624

Configuring command injection check by using the CLI 2767
Configuring relaxation rules for command injection protection check 2768
Example for relaxation rule for Regex in header 2769
Example for relaxation rule with valueType as regex in cookie 2769
Configuring command injection check by using NetScaler GUI 2769
View or customize command injection patterns by using the GUI 2769
Viewing command injection traffic and violation statistics 2771
Viewing HTML command injection statistics by using the NetScaler GUI 2775
Custom keyword support for HTML payload 2775
Add custom keywords using the CLI 2776
Add custom keywords using the GUI 2777
View custom keyword statistics using the CLI 2778
View custom keyword statistics the GUI 2778
XML external entities (XXE) Attack Protection 2779
Configure XML external entities (XXE) injection protection 2779
Configure XXE injection check by using NetScaler GUI 2780
Viewing XXE injection traffic and violation statistics 2780
Viewing XXE injection statistics by using the NetScaler GUI 2781
Buffer overflow check 2781
Using the command line to configure the Buffer Overflow security check 2782
Configure buffer overflow security check by using the NetScaler GUI 2782
Using the Log Feature with the Buffer Overflow Security Check 2783
Statistics for the Buffer Overflow violations 2786
Highlights 2787
Web App Firewall support for Google web toolkit 2788
What is GWT 2788
How a GWT request works 2789
Web App Firewall protection for GWT applications 2790

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Cookie Protection 2793
Cookie consistency check 2794
Cookie hijacking protection 2797
Limitations 2798
How cookie hijacking protection works 2798
Scenario 1: User accessing the first webpage without session cookie 2799
Scenario 2: User accessing successive webpages over new TLS connection with session cookie 2800
Scenario 3: Attacker impersonating as a non-authenticated user 2800
Scenario 4: Attacker impersonating as an authenticated user 2801
Configure cookie hijacking by using the CLI 2802
Configure cookie hijacking by using the NetScaler GUI 2802
Add a relaxation rule for cookie consistency validation by using the NetScaler GUI 2803
View cookie hijacking traffic and violation statistics by using the CLI 2803
View cookie hijacking traffic and violation statistics by using the GUI 2808
SameSite cookie attribute 2808
Setting cookie attribute value 2809
Configure the SameSite attribute in the Web App Firewall profile by using the CLI 2809
Enable the `Samesite' cookie attribute 2809
Set same site cookie attribute value for Web Application Firewall session cookies 2809
Configure the SameSite cookie attribute in the Web App Firewall profile by using the GUI 2810
Data leak prevention checks 2811
Credit card check 2811
Using the command line to configure the credit card check 2812
Using the GUI to configure the credit card check 2813
Using the learn feature with the credit card check 2815
Using the log feature with the credit card check 2816
Statistics for the credit card violations 2818

JSON SQL Injection protection check 2897

Configure JSON SQL Injection protection 2897

Add application firewall profile of type JSON 2898

Example 2898

Configure JSON SQL Injection action 2898

Configure JSON SQL Injection type 2898

Example 2898

Example 2899

Configure JSON SQL Injection protection by using GUI 2900

Configure fine grain relaxation for JSON SQL injection protection 2901

Points to Consider 2902

Configure JSON fine grain relaxation for command injection attacks using command interface 2902

JSON Cross-Site Scripting protection check 2903

Configure JSON Cross-Site Scripting protection 2903

Add application firewall profile of type JSON 2903

Example 2904

Configure JSON Cross-Site Scripting action 2905

Example 2905

Example 2905

Configure JSON Cross Site Scripting (cross-site scripting) protection by using GUI 2905

Configure fine grained relaxation for JSON-based cross-site scripting 2906

Points to Consider 2907

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure JSON fine grain relaxation for cross-site scripting (XSS) injection attacks using command interface 2907

JSON command injection protection check 2909

How command injection protection works 2910

Keywords and special characters denied for command injection check 2910

Configuring JSON command injection check by using the CLI 2911

Configuring relaxation rules for JSON command injection protection check 2912

Example for relaxation rule for Regex in header 2912

Configure JSON command injection check by using the GUI 2912

Viewing command injection traffic and violation statistics 2913

Viewing JSON command injection statistics by using the NetScaler GUI 2917

Configure fine grain relaxation for JSON command injection 2919

Points to Consider 2919

Configure JSON fine grain relaxation for command injection attacks using command interface 2920

Custom keyword support for JSON payload 2921

Add custom keywords using the CLI 2922

View the statistics of the custom keyword in CLI 2922

Add custom keywords using the GUI 2923

View the statistics of the custom keyword in GUI 2924

Managing content types 2925

To set the default request content type by using the command line interface 2926

Example 2926

To remove the user-defined default request content type by using the command line interface 2926

Example 2926

To set the default response content type by using the command line interface 2927

Example 2927

To remove the user-defined default response content type by using the command line interface 2927

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example 2928

To add a content type to the allowed content types list by using the command line interface 2928

Example 2928

To remove a content type from the allowed content types list by using the command line interface 2928

Example 2928

Manage urlencoded and multipart-form content types 2929

To manage the default and allowed content types by using the GUI 2929

To manage Urlencoded and Multipart-form content types by using the NetScaler GUI 2930

Profiles 2931

Built-in profiles 2931

User-defined profiles 2932

Creating Web App Firewall profiles 2933

To create a Web App Firewall profile by using the command line interface 2934

Example 2934

To create a Web App Firewall profile by using the GUI 2935

Configure fake account detection rules 2936

Enable fake account detection feature 2937

Bind fake account rules 2937

Configure Web App Firewall fake account detection rule by using the GUI 2938

Enforce HTTP RFC compliance 2939

Block or bypass non-RFC compliant requests at global level 2939

To block or bypass invalid non-RFC complaint HTTP requests by using the command line interface 2940

To display malformed request action settings 2940

To block or bypass invalid non-RFC complaint HTTP requests by using the NetScaler GUI 2940

Block or bypass non-RFC compliant requests at profile level 2941

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure an RFC profile in the Web App Firewall profile by using the command line interface 2942
Example 2942
To configure an RFC profile in the Web App Firewall profile by using the GUI 2942
Configuring Web App Firewall profiles 2942
To configure a Web App Firewall profile by using the command line 2943
Example 2943
Bind relaxation rule to a Web App Firewall profile 2943
To bind security exemption or relaxation rules by using the CLI 2944
To bind security exemption or relaxation rules by using the GUI 2944
To configure a Web App Firewall profile by using the GUI 2944
Confidential fields in WAF profile 2946
Web Application Firewall profile settings 2946
Changing an Web App Firewall profile type 2952
To change an Web App Firewall profile type by using the command line interface 2952
Example 2953
To change an Web App Firewall profile type by using the GUI 2953
Exporting and importing an Web App Firewall profile 2953
Exporting Web App Firewall profiles with the CLI 2954
Importing Web App Firewall Profiles with the CLI 2956
Exporting and Importing Web App Firewall Profiles with the GUI 2957
Highlights 2958
Debugging Tips 2958
Ease of troubleshooting with Web Application Firewall logs 2959
Configuring verbose log level by using the command interface 2959
Example 2959
Configuring verbose log level by using the NetScaler GUI 2959
Verbose logging for JSON security checks (SQL, CMD, and cross-site scripting) 2960

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure verbose logging for JSON security protection by using the CLI 2961

Configuring verbose log level by using the NetScaler GUI 2961

Manage global lists to bypass WAF or deny requests 2962

Configure the global bypass and deny list using the CLI 2962

Bind the Web App Firewall profile with a global bypass list 2963

Bind the Web App Firewall profile with a global deny list 2965

Configure the global bypass and deny list using the GUI 2966

Add a global bypass list 2968

Add a global deny list 2968

Support for Global Deny List 2969

Manage Global Deny lists status 2969

Pre-requisites 2969

To disable the Global Deny Lists feature by using CLI 2970

File upload protection 2970

How file upload works 2971

Configure file type upload by using NetScaler CLI 2971

Example 2971

Example 2972

Configure file upload security protection by using NetScaler GUI 2972

Configure file upload relaxation rule by using NetScaler GUI 2972

Configuring and using the Learning feature 2974

To configure the learning settings by using the command line interface 2977

Example 2977

To reset learning settings to their defaults by using the command line interface 2978

To display the learning settings for a profile by using the command line interface 2978

To display unreviewed learned rules or relaxations for a profile by using the command line interface 2978

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To remove specific unreviewed learned rules or relaxations from the learning database by using the command line interface 2978

Example 2979

To remove all unreviewed learned data by using the command line interface 2979

To export learning data by using the command line interface 2979

Example 2979

To configure the Learning feature by using the GUI 2979

To review learned rules or relaxations by using the GUI 2981

Dynamic profiling 2982

Configure dynamic profiling by using the NetScaler command interface 2983

Configure dynamic learning 2983

Example 2983

Configure auto deployment grace period 2983

Example 2984

Configuring dynamic profiling by using the NetScaler GUI 2984

Export and import of relaxation rules 2985

How to export and import relaxation rules 2985

Import archived relaxation rules file by using CLI 2986

Export the archived file to the selected appliance by using the CLI 2987

To export relaxation rules by using NetScaler GUI 2987

To import relaxation rules by using NetScaler GUI 2988

Supplemental Information about profiles 2988

Configuration variable support 2989

PCRE character encoding format 2990

Inverted PCRE Expressions 2992

Disallowed Names for Web App Firewall Profiles 2993

Custom error status and message for HTML, XML, and JSON error object 2995

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure custom status code and message for HTML error object in a WAF profile by using the CLI 2995

Configure custom status code and message for XML error object in a WAF profile by using the CLI 2996

Configure custom status code and message for JSON error object in a WAF profile by using the CLI 2996

Configure custom status code and message for HTML, JSON, or XML error object in a WAF profile by using the GUI 2996

Policy labels 2997

To create an Web App Firewall policy label by using the command line 2997

Example 2997

To bind a policy to a policy label by using the command line 2998

Example 2998

To configure an Web App Firewall policy label by using the GUI 2998

Policies 2999

Web App Firewall Policies 3000

Creating and configuring Web App Firewall policies 3002

To create and configure a policy by using the command line interface 3002

Example 3002

To create and configure a policy by using the GUI 3003

To create or configure a Web App Firewall rule (expression) 3003

To add a firewall rule (expression) by using the Add Expression dialog box 3006

Binding Web App Firewall policies 3007

To bind an Web App Firewall policy by using the command line interface 3008

Example 3008

Configure log expressions 3008

Example configuration 3008

Example logs 3009

To bind an Web App Firewall policy by using the GUI 3010

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Viewing a policy bindings 3011
To view bindings for an Web App Firewall policy 3011
Supplemental information about Web App Firewall policies 3012
Correct but unexpected behavior 3012
Auditing policies 3012
To create an auditing server by using the command line interface 3012
Example 3013
To modify or remove an auditing server by using the command line interface 3013
Example 3013
To create or configure an auditing server by using the GUI 3014
To create an auditing policy by using the command line interface 3015
Example 3015
To configure an auditing policy by using the command line interface 3015
Example 3015
To configure an auditing policy by using the GUI 3015
Imports 3016
HTML error object 3016
XML error object 3018
XML Schema 3018
WSDL 3018
API Specification Import Object 3019
Import and export files 3019
To import a file by using the command line interface 3019
Example 3020
To import a file by using the GUI 3020
To export a file by using the GUI 3021
To edit an HTML or XML Error Object in the GUI 3021
Global configuration 3022

Engine settings 3022

To configure engine settings by using the command line interface 3024

Example 3025

To configure engine settings by using the NetScaler GUI 3025

Confidential fields 3027

To add a confidential field by using the command line interface 3029

Example 3029

To modify a confidential field by using the command line interface 3029

Example 3029

To remove a confidential field by using the command line interface 3030

To configure a confidential field by using the GUI 3030

Examples 3031

Field types 3032

To add a field type by using the command line interface 3033

Example 3033

To modify a field type by using the command line interface 3033

Example 3033

To remove a field type by using the command line interface 3034

To configure a field type by using the GUI 3034

Examples 3034

XML content types 3035

To add an XML content type pattern by using the command line interface 3035

Example 3035

To remove an XML content type pattern by using the command line interface 3036

To configure the XML content type list by using the GUI 3036

JSON content types 3036

To add a JSON content type pattern by using the command line interface 3037

Example 3037

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure the JSON content type list by using the GUI 3037
Statistics and reports 3038
The Web App Firewall statistics 3038
Relaxation hit statistical counter 3038
To display statistics for relaxation rule hit counters by using the CLI 3039
To display statistics for relaxation rule hit counters by using the GUI 3040
The Web App Firewall Reports 3040
The PCI DSS report 3040
The Web App Firewall configuration report 3041
Monitor Global Web App Firewall session limit 3042
View global Web App Firewall session statistics 3042
To view statistics by using CLI 3042
To view statistics by using GUI 3043
Web App Firewall logs 3043
NetScaler (Native) format logs 3043
Common Event Format (CEF) logs 3044
Log geolocation in the Web App Firewall violation messages 3047
Configure log action and other log parameters using command interface 3049
Customize Web App Firewall logs 3050
Configure Syslog policy to segregate Web App Firewall logs 3051
Send the Application Firewall messages to an external SYSLOG server 3053
View Web App Firewall logs 3054
Highlights 3056
Mask sensitive data using regex pattern 3056
Mask sensitive data in Web Application Firewall logs 3057
Add a Web Application Firewall profile 3057
Bind a log expression with the Web Application Firewall profile 3057
Mask sensitive data in Web Application Firewall logs by using NetScaler GUI 3058

Configure CAPTCHA by using the CLI 3263
Configure CAPTCHA by using the GUI 3264
Configure bot signature setting 3264
Configure bot allow list by using NetScaler GUI 3265
Configure bot block list by using NetScaler GUI 3266
Configure CAPTCHA for IP reputation 3267
How CAPTCHA works in NetScaler bot management 3268
Configure CAPTCHA settings by using the NetScaler GUI 3268
Bot Transactions Per second (TPS) 3269
Configure bot transactions per second (TPS) using CLI 3270
Enable bot transaction per second (TPS) 3270
Bind TPS settings to bot management profile 3270
Configure bot transactions per second (TPS) by using the NetScaler GUI 3271
Bot signature auto update 3272
How bot signature auto update works 3272
Configure bot signature auto update 3273
Enable bot signature auto update 3273
Configure proxy server settings (optional) 3273
Configure bot signature auto update using the NetScaler GUI 3273
Update the signature manually 3274
Update a signature file using the CLI 3274
Update the signature file using the GUI 3274
Import default signatures without internet access 3275
Bot Management 3276
Bot Management 3277
Bot signature alert Articles 3278
Bot signature update for June 2026 3278
Bot signature version 3278

Add a cache redirection virtual server in transparent mode by using the GUI 3503
Bind policies to the cache redirection virtual server 3503
Bind policies to a cache redirection virtual server by using the CLI 3503
Bind a user-defined policy to a cache redirection virtual server by using the GUI 3505
Unbind a policy from a cache redirection virtual server 3505
Unbind a policy from a cache redirection virtual server by using the command CLI 3505
Unbind a user-defined policy from a cache redirection virtual server by using the GUI 3506
Create a load balancing virtual server 3506
Create a load balancing virtual server by using the CLI 3506
Create a load balancing virtual server by using the GUI 3508
Configure an HTTP service 3508
Configure an HTTP service by using the CLI 3508
Modify or remove a service by using the CLI 3510
Add an HTTP service by using the GUI 3510
Bind/unbind a service to/from a load balancing virtual server 3510
Bind a service to a load balancing virtual server by using the CLI 3511
Unbind a service from a load balancing virtual server by using the CLI 3512
Bind/unbind a service from a load balancing virtual server by using the GUI 3512
Disable the use the proxy port setting for transparent caching 3512
Assign a port range to the NetScaler appliance 3513
Assign a source port range to a NetScaler appliance by using the CLI 3513
Assign a source port range to a NetScaler appliance by using the appliance GUI 3513
Enable load balancing virtual servers to redirect requests to cache 3513
Enable load balancing virtual servers to redirect requests to the cache by using the CLI 3513
Turn off caching for a load balancing virtual server by using the CLI 3515
Enable or disable load balancing virtual servers to redirect requests to the cache by using the GUI 3515
Configure forward proxy redirection 3515

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a DNS service 3517
Create a DNS service by using the CLI 3517
Add a DNS service by using the GUI 3518
Create a DNS load balancing virtual server 3519
Create a DNS load balancing virtual server by using the CLI 3519
Create a DNS load balancing virtual server by using the GUI 3520
Bind the DNS service to the virtual server 3520
Bind the DNS service to the load balancing virtual server by using the CLI 3520
Unbind a DNS service from the load balancing virtual server by using the CLI 3521
Bind/Unbind a DNS service to/from a load balancing virtual server by using the GUI 3521
Configure a client web browser to use a forward proxy 3522
Configure reverse proxy redirection 3522
Configure mapping policies 3523
Configure a mapping policy for reverse proxy mode by using the CLI 3524
Configure a mapping policy for reverse proxy mode by using the GUI 3525
Bind the mapping policy to the cache redirection virtual server by using the CLI 3526
Bind the mapping policy to the cache redirection virtual server by using the GUI 3527
Selective cache redirection 3527
Enable content switching 3528
Enable content switching by using the CLI 3528
Enable cache redirection and load balancing by using the GUI 3529
Configure a load balancing virtual server for the cache 3530
Configure a cache redirection policy for a specific type of content 3530
Configure policies for content switching 3531
Create a content switching policy by using the command CLI 3531
Create a rule-based content switching policy by using the GUI 3533
Bind the content switching policy to a cache redirection virtual server by using the CLI 3534
Bind the content switching policy to a cache redirection virtual server by using the GUI 3536

Configure precedence for policy evaluation 3537

Configure precedence for policy evaluation by using the CLI 3537

Configure precedence for policy evaluation by using the GUI 3538

Administer a cache redirection virtual server 3538

View cache redirection virtual server statistics 3538

View statistics for a cache redirection virtual server by using the CLI 3539

View statistics for a cache redirection virtual server by using the GUI 3540

View the statistics of a cache redirection virtual server by using the monitoring and dashboard utilities 3540

Enable or disable a cache redirection virtual server 3540

Enable or disable a cache redirection virtual server by using the CLI 3540

Enable or disable a cache redirection virtual server by using the GUI 3542

Direct policy requests to cache instead of origin web server 3543

Change the destination for a policy request to the origin or the cache by using the CLI 3543

Change the destination for a policy hit to the origin or the cache by using the GUI 3544

Back up a cache redirection virtual server 3545

Specify a backup cache redirection virtual server by using the CLI 3545

Specify a backup cache redirection virtual server by using the GUI 3546

Manage client connections for a virtual server 3546

Configure client timeout 3547

Configure client timeout by using the CLI 3547

Configure client timeout by using the GUI 3548

Insert Via headers in the requests 3548

Enable or disable Via-header insertion in client requests by using the CLI 3549

Enable or disable Via-header insertion in client requests by using the GUI 3550

Reuse TCP connections 3550

Enable or disable the reuse of TCP connections by using the CLI 3550

Enable or disable the reuse of TCP connections by using the GUI 3551

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure delayed connection cleanup 3552

Enable of disable the down state flush option by using the CLI 3552

Enable or disable the reuse of TCP connections by using the GUI 3553

Enable external health check for UDP and non-HTTP TCP virtual servers 3553

To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI 3554

To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI 3554

N-Tier cache redirection 3554

How N-tier cache redirection Is implemented 3555

Setup necessary for configuring N-Tier CRD 3556

How N-tier cache redirection works during a cache hit 3556

Traffic flow 3557

How N-tier cache redirection works during a cache bypass 3558

Traffic flow 3558

How N-tier cache redirection works during a cache miss 3559

Traffic flow 3560

Configure the upper-tier NetScaler appliances 3560

Configure an upper-tier appliance for n-tier cache redirection by using the command CLI 3560

Configure an upper-tier appliance for n-tier cache redirection by using the GUI 3561

Configure the lower-tier NetScaler appliances 3562

Configure a lower-tier appliance for n-tier cache redirection by using the CLI 3562

Configure a lower-tier appliance for n-tier cache redirection by using the GUI 3562

Translate destination IP address of a request to origin IP address 3563

Use case 3564

To translate the destination IP address and port number of the request to origin IP address by using the CLI 3566

To translate the destination IP address and port of the request to origin IP address by using the GUI 3566

Clustering 3567

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Supportability matrix for NetScaler cluster 3567
Prerequisites 3577
Cluster overview 3578
Synchronization across cluster nodes 3580
Striped, partially striped, and spotted configurations 3581
List of spotted configuration 3584
ARP owner support for striped IP 3585
Neighbor discovery owner support for striped IPv6 address 3585
To enable ND owner on a node by using the CLI 3585
To enable ND owner on a node by using the GUI 3586
Communication in a cluster setup 3586
Traffic distribution in a cluster setup 3589
Cluster node groups 3591
Cluster and node states 3592
Routing in a cluster 3592
IPv4 routing in L2 cluster 3593
Adding spotted SNIP address and enabling dynamic routing 3593
VTYSH IPv4 OSPF configuration 3593
VTYSH IPv4 BGP configuration 3594
IPv6 routing in L2 cluster 3596
Enable IPv6 routing 3596
Adding spotted SNIP6 address and enabling dynamic routing 3596
VTYSH IPv6 BGP configuration 3597
Install IPv6 learned routes 3598
Routing in a L3 cluster 3599
Deployment scenario for BGP in L3 cluster 3599
IP addressing for a cluster 3600
Best practices for VLAN bindings and route configuration while joining a node to the cluster 3602

© 1997–2026 Citrix Systems, Inc. All rights reserved.

VLAN IP bindings 3602
Routing configuration 3602
Configuring layer 3 clustering 3603
Understanding the L3 cluster 3603
Architecture 3603
Example 3605
Points to consider before configuring the L3 cluster 3606
Configuring the L3 cluster 3607
Configuring the following by using the CLI 3607
Advertising cluster IP address of a L3 cluster 3611
To enable the host route option of the cluster IP address by using the CLI 3611
Spotted, partially striped configurations on L3 cluster 3611
Configuring the following by using the CLI 3612
Configure node group 3613
Configuring the following by using the CLI 3614
Configuring the following by using the CLI 3614
Traffic distribution in a L3 cluster 3615
Setting up a NetScaler cluster 3616
Setting up inter-node communication 3616
To set up the cluster backplane, do the following for every node 3617
Important points to note when setting up the cluster backplane 3617
UDP based tunnel support for L2 and L3 cluster 3619
Configuring a UDP based tunnel 3620
CLI procedures 3620
GUI procedures 3621
Creating a NetScaler cluster 3621
Create a cluster by using the command line interface 3622
To create a cluster by using the GUI 3626

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Strict mode support for sync status of the cluster 3626
To enable the strict mode by using the CLI 3627
To view the status of strict mode by using the CLI 3627
To view the sync failure reason of a cluster node by using the GUI 3628
Add a node to the cluster 3628
Add a node to the cluster by using the CLI 3629
Add a node to the cluster by using the GUI 3633
Join a previously added node to the cluster by using the GUI 3633
Viewing the details of a cluster 3634
View details of a cluster instance by using the CLI 3634
View details of a cluster node by using the CLI 3634
View details of an interface by using the CLI 3634
View details of a cluster instance by using the GUI 3635
To view details of a cluster node by using the GUI 3635
Distributing traffic across cluster nodes 3635
Policy-based backplane steering 3635
CLI commands for IPv4 3636
CLI commands for IPv6 3636
Limitations 3636
Using the Equal Cost Multiple Path (ECMP) 3637
To configure ECMP on the cluster by using the command line interface 3639
Router monitoring cluster nodes in ECMP deployment 3642
To configure ECMP for static routes traffic distribution by using the command line interface 3642
Use Case: ECMP with BGP routing 3642
Configuration of cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol 3643
Use Case: Cluster ECMP by using Cisco Nexus 7000 switch with routing Protocol 3644
Prerequisites 3644
Configuring by using the CLI on a NetScaler appliance 3644

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Using cluster link aggregation 3652
Points to consider 3652
Backup and restore support of cluster LA on NetScaler MPX 3655
Static cluster link aggregation 3656
To configure a static cluster LA channel by using the CLI 3656
Dynamic cluster link aggregation 3658
Points to remember 3658
Configure a DCLA channel by using the CLI 3658
Link redundancy in a cluster with LACP 3660
Using USIP mode in cluster 3661
USIP mode traffic distribution 3661
USIP mode 3661
USIP `useproxyport` scenarios 3662
Limitations 3662
USIP mode deployment 3662
Configure the following using CLI 3662
Static route advertisement to upstream routers 3665
Managing the NetScaler cluster 3667
Configuring linksets 3668
To configure a linkset by using the CLI 3670
To configure a linkset by using the GUI 3671
Node groups for spotted and partially striped configurations 3671
Behavior of node groups 3672
General behavior of a cluster node group 3672
Backing up nodes in a node group 3673
Configuring node groups for spotted and partially striped configurations 3674
To configure a node group by using the command line interface 3675
To configure a node group by using the configuration utility 3676

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring redundancy for node groups 3677

Configuring redundancy for node groups 3679

Disabling steering on the cluster backplane 3679

Synchronizing cluster configurations 3681

Display list of commands failed during cluster config synchronization 3682

Sample configuration 3682

Synchronizing time across cluster nodes 3684

To enable/disable PTP by using the command line interface 3684

To enable/disable PTP by using the configuration utility 3685

Synchronizing cluster files 3685

To synchronize cluster files by using the command line interface 3686

To synchronize cluster files by using the configuration utility 3686

Viewing the statistics of a cluster 3687

To view the statistics of a cluster instance by using the command line interface 3687

To view the statistics of a cluster node by using the command line interface 3687

To view the statistics of a cluster instance by using the configuration utility 3687

To view the statistics of a cluster node by using the configuration utility 3687

Discovering NetScaler appliances 3688

To discover appliances by using the GUI 3688

Disabling a cluster node 3689

To disable a cluster node by using the command line interface 3689

To disable a cluster node by using the configuration utility 3689

Removing a cluster node 3690

To remove a cluster node by using the CLI 3690

To remove a cluster node by using the GUI 3691

Removing a node from a cluster deployed using cluster link aggregation 3691

To remove a node from a cluster that uses cluster link aggregation as the traffic distribution mechanism 3691

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Detecting jumbo probe on a cluster 3693
Route monitoring for dynamic routes in cluster 3694
To bind a cluster node using the CLI 3694
Monitoring cluster setup using SNMP MIB with SNMP link 3695
Configuring SNMP MIB on CLIP 3695
Cluster SNMP trap messages 3697
Monitoring command propagation failures in a cluster deployment 3698
Graceful shutdown of nodes 3698
Graceful handling of Nodes in cluster upgrade 3699
Graceful handling of nodes during a new node addition 3700
Configuring graceful shutdown of nodes in a cluster 3701
To retain existing connections at the global (cluster) level by using the CLI 3702
To retain existing connections of a specific virtual server in the cluster by using the CLI 3702
To set a cluster node to passive state by using the CLI 3702
To configure graceful shutdown of nodes by using the GUI 3703
Graceful shutdown of services 3704
To configure graceful shutdown for a service by using the CLI 3704
To configure graceful shutdown for a service by using the GUI 3708
To configure a TROFS code or string in a monitor by using the CLI 3708
To configure a TROFS code or string in a monitor by using the GUI 3708
IPv6 ready logo support for clusters 3708
Supportable configurations for testing IPv6 core protocols 3709
Global configuration 3709
Basic IPv6 configuration 3709
Example 1 3711
Example 2 3712
More IPv6 cluster configuration 3712
Example 3713

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Managing cluster heartbeat messages 3715
To manage heartbeat messages on a node interface by using the NetScaler CLI 3715
Configure secure heartbeats 3715
Configure secure heartbeats using the CLI 3716
Configure secure heartbeats using the GUI 3718
Configuring owner node response status 3718
To set owner node response status by using the NetScaler CLI 3719
Example 3719
To set owner node response status by using the NetScaler GUI 3719
To edit owner node response status by using the NetScaler GUI 3719
Monitor static route (MSR) support for inactive nodes in a spotted cluster configuration 3719
VRRP interface binding in a single node active cluster 3719
Cluster setup and usage scenarios 3721
Creating a two-node cluster 3721
Migrating an HA setup to a cluster setup 3721
To convert an HA setup to a cluster setup by using the CLI 3722
To convert an HA setup to a cluster setup by using the GUI 3726
Migrate a two-node cluster to an HA setup 3728
Before you begin 3729
Procedure 3729
Transitioning between a L2 and L3 Cluster 3731
Transitioning a cluster from L2 to L3 3731
Transitioning a cluster from L3 to L2 3731
Setting up GSLB in a cluster 3732
Support for GSLB parent-child topology in a cluster 3734
To set up GSLB parent-child topology in a cluster by using the CLI 3734
Parent site 3734
Child site 3735

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To set up GSLB parent-child topology in a cluster by using the GUI 3736
Using cache redirection in a cluster 3737
Using cluster LA channel with linksets 3738
To configure cluster LA channel and linksets by using the CLI 3738
Backplane on LA channel 3739
To deploy a cluster with the backplane interfaces as LA channels 3739
Common interfaces for client and server and dedicated interfaces for backplane 3741
Common switch for client, server, and backplane 3743
Common switch for client and server and dedicated switch for backplane 3747
Different switch for every node 3750
Sample cluster configurations 3751
Using VRRP in a cluster setup 3755
IP based VRRP 3755
Configuring IP based VRRP for IPv4 3755
To add a VRID by using the CLI 3756
To bind the VRID to VIP address by using the CLI 3756
To add a VRID by using the GUI 3756
To bind the VRID to a VIP address by using the GUI 3756
Configuring IP based VRRP for IPv6 3757
To add a VRID6 by using the CLI 3757
To bind the VRID6 to VIP6 address by using the CLI 3757
To add a VRID6 by using the GUI 3757
To bind the VRID6 to a VIP6 address by using the GUI 3757
Interface based VRRP 3758
Configuring interface based VRRP for IPv4 3758
To add a VRID by using the CLI 3758
To bind the VRID to an interface by using the CLI 3759
To add a VRID and bind it to interfaces by using the GUI 3759

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring interface based VRRP for IPv6 3759
To add a VRID6 by using the CLI 3760
To bind the VRID6 to an interface by using the CLI 3760
To add a VRID6 and bind it to interfaces by using the GUI 3760
Monitoring services in a cluster using path monitoring 3760
How path monitoring works 3761
Configuring path monitoring 3762
To enable path monitoring for services/service groups by using the CLI 3763
To enable path monitoring for services/service groups by using the GUI 3764
Backup and restore of cluster setup 3764
Back up a cluster Setup 3764
How to back up a cluster setup 3767
Restore a cluster setup 3768
How to restore a cluster node 3768
To restore a cluster node by using the CLI 3768
Upgrading or downgrading the NetScaler cluster 3769
Points to note before upgrading or downgrading the cluster 3772
To upgrade or downgrade the software of the cluster nodes 3773
Test the application traffic on a single node during cluster upgrade 3774
Operations supported on individual cluster nodes 3775
Support for heterogeneous cluster 3776
Points to note 3777
Deploying NetScaler clusters on public cloud platforms 3777
Deploy a NetScaler cluster on AWS 3778
Architecture 3778
Prerequisites 3778
Set up the infrastructure 3780
Deploy NetScaler VPX instances on AWS 3781

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create the cluster IP (CLIP) in AWS 3781

Configure the NetScaler cluster 3782

Post-configuration tuning 3783

Verification 3783

Configure cluster networking and load balancing 3783

Troubleshooting and best practices 3784

Deploy NetScaler cluster on Google Cloud Platform 3785

Architecture overview 3785

Cluster deployment methods on GCP 3786

Deploy a NetScaler cluster on GCP with cloud router using dynamic routing 3786

Prerequisites 3787

Deployment steps for a NetScaler cluster with Google Cloud Router using Dynamic Routing 3787

FAQs 3797

How many NetScaler appliances can be included in a single NetScaler cluster? 3797

Can a NetScaler appliance be a part of multiple clusters? 3797

What is a cluster IP address? What is its subnet mask? 3797

How can I make a specific cluster node as the cluster configuration coordinator? 3797

Why are the network interfaces of a cluster represented in 3-tuple (n/u/c) notation instead of the regular 2-tuple (u/c) notation? 3798

How can I set the host name for a cluster node? 3798

Can I automatically detect NetScaler appliances so that I can add them to a cluster? 3798

Is the traffic serving capability of a cluster affected if a node is removed or disabled or reboot or shutdown or made inactive? 3798

I have multiple standalone appliances, each of which has different configurations. Can I add them to a single cluster? 3798

Can I migrate the configurations of a standalone NetScaler appliance or an HA setup to the clustered setup? 3799

Is backplane interfaces part of the L3 VLANs? 3799

How can I configure a cluster that includes nodes from different networks? 3799

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How can I configure/un-configure the NSVLAN on a cluster? 3800

I have a cluster set up where some NetScaler nodes are not connected to the external network. Can the cluster still function normally? 3800

How can deployments that require MAC-Based Forwarding (MBF) be supported in a clustered setup? 3800

Can I run commands from the NSIP address of a cluster node? 3800

Can I disable configuration propagation among cluster nodes? 3801

Can I change the NSIP address or change the NSVLAN of a NetScaler appliance when it is a part of the cluster? 3801

Does the NetScaler cluster support L2 and L3 VLANs? 3801

How can I configure SNMP on a NetScaler cluster? 3801

What details must I have available when I contact technical support for cluster-related issues? 3802

Can I use striped IP addresses as the default gateway of servers? 3802

Can I view the routing configurations of a specific cluster node from the cluster IP address? 3802

How can I specify the node for which I want to set the LACP system priority? 3803

How are IP tunnels configured in a cluster setup? 3803

How can I add a failover interface set (FIS) on the nodes of a NetScaler cluster? 3803

How are net profiles configured in a cluster setup? 3804

How can I configure WIonNS in a cluster setup? 3804

Can the cluster LA channel be used for management access? 3805

How cluster nodes communicate to each other and what are the different types of traffic that goes through the backplane? 3805

What gets routed over the GRE tunnel for the Layer 3 cluster? 3806

How Node to Node Messaging (NNM) and heartbeat messages are exchanged, and how are they routed? 3806

What are the MTU recommendations for layer 3 cluster tunneled traffic? 3806

How the global hash key is generated and shared across all nodes? 3806

What is the need of `set rsskeytype –rsskey symmetric` command for *:*, USIP on, `useproxyport` off, topologies? 3807

© 1997–2026 Citrix Systems, Inc. All rights reserved.

What are the factors that contribute to change the CCO node? 3807

Can I form a cluster with nodes of different hardware platforms? 3807

Troubleshooting the NetScaler cluster 3807

Tracing the packets of a NetScaler cluster 3808

To trace packets of a standalone appliance 3809

To trace packets of a cluster 3809

Merge multiple trace files 3810

Examples 3810

Capturing SSL Session Keys During a Trace 3811

Advantages of using SSL session keys 3812

Limitations of using SSL session keys 3812

To capture SSL session keys by using the command line interface (CLI) 3812

To configure SSL session keys by using the NetScaler GUI 3813

To import the SSL Master Keys into Wireshark 3813

Troubleshooting common issues 3813

While joining a node to the cluster, I get the following message, "ERROR: Invalid interface name/number." What must I do to resolve this error? 3813

While joining a node to the cluster, I get the following message, "ERROR: Clustering cannot be enabled, because the local node is not a member of the cluster." What must I do to resolve this error? 3813

While joining a node to the cluster, I get the following message, "ERROR: Connection refused." What must I do to resolve this error? 3814

While joining a node to the cluster, I get the following message, "ERROR: License mismatch between the configuration coordinator and the local node." What must I do to resolve this error? 3814

What must I do when the configurations of a cluster node are not in synchronize with the cluster configurations? 3814

Why does the node state show "INACTIVE" when the node health shows "UP"? 3815

How can I resolve the health of a node when its health shows "NOT UP"? 3815

© 1997–2026 Citrix Systems, Inc. All rights reserved.

What must I do when the health of a node shows as "NOT UP" and the reason indicates that configuration commands have failed on a node? 3815

When I run the set virtual server command, I get the following message, "No such resource." What must I do to resolve this issue? 3815

I cannot configure the cluster over a Telnet session. What must I do? 3815

I notice a significant time difference across the cluster nodes. What must I do to resolve this issue? 3816

What must I do, if there is no connectivity to the cluster IP address and the NSIP address of a cluster node? 3816

What must I do to recover a cluster node that has connectivity issues? 3816

Some nodes of the cluster have two default routes. How can I remove the second default route from the cluster node? 3816

The cluster functionality gets affected when an existing cluster node comes online. What must I do to resolve this issue? 3817

Content Switching 3818

How Content Switching Works 3818

Configure basic content switching 3821

Enable content switching 3822

Enable content switching by using the CLI 3822

Enable content switching by using the GUI 3823

Create content switching virtual servers 3823

Create a virtual server by using the CLI 3823

Add a content switching virtual server by using the GUI 3824

Content switching virtual server statistics 3824

View statistics of content switching virtual server by using the CLI 3824

View statistics of content switching virtual server by using the GUI 3824

Configure a load balancing setup for content switching 3825

Configure a content switching action 3825

Configure an action that specifies the name of the target load balancing virtual server 3826

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create and verify a content switching action that specifies the name of the target load balancing virtual server, by using the CLI 3826

Configure a content switching action that specifies the name of the target load balancing virtual server, by using the GUI 3827

Configure an action that specifies an expression for selecting the target at run time 3827

Create a content switching action that specifies an expression, by using the CLI 3828

Configure a content switching action that specifies an expression by using the GUI 3829

Configure content switching policies 3829

Create a content switching policy by using the CLI 3829

Rename a content switching policy by using the CLI 3830

Rename a content switching policy by using the GUI 3830

Create a content switching policy by using the GUI 3830

Configure content switching policy labels 3831

Create a content switching policy label by using the CLI 3831

Rename a content switching policy label by using the CLI 3832

Rename a content switching policy label by using the GUI 3832

Bind a policy to a content switching policy label by using the CLI 3832

Unbind a policy from a policy label by using the CLI 3833

Remove a policy label by using the CLI 3834

Manage a content switching policy label by using the GUI 3834

Bind policies to a Content Switching virtual server 3834

Bind a policy to a content switching virtual server and select a target load balancing virtual server by using the CLI 3834

Bind a policy to a content switching virtual server and select a target load balancing virtual server by using the GUI 3835

Configure policy-based logging for content switching 3836

Configure policy-based logging for a content switching policy by using the CLI 3836

Configure policy-based logging for a content switching policy by using the GUI 3837

Verify the configuration 3837

© 1997–2026 Citrix Systems, Inc. All rights reserved.

View the properties of content switching virtual servers 3837

View the properties of content switching virtual servers by using the CLI 3838

Example 3838

View content switching policies 3841

View the properties of content switching policies by using the CLI 3842

View the properties of content switching policies by using the GUI 3842

View a content switching virtual server configuration by using the visualizer 3842

View a content switching configuration by using the Visualizer in the GUI 3843

Customizing the basic content switching configuration 3844

Support for Multiple Ports for HTTP and SSL Type Content Switching Virtual Servers 3845

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the command line 3845

Example 3845

To configure an HTTP or SSL content switching virtual server to listen on multiple ports by using the configuration utility 3846

Configuring per-VLAN Wildcard Virtual Servers 3846

To configure a wildcard virtual server that listens to a specific VLAN by using the command line interface 3847

To configure a wildcard virtual server that listens to a specific VLAN by using the configuration utility 3847

Configuring the Microsoft SQL Server Version Setting 3847

To set the Microsoft SQL Server version parameter by using the command line interface 3847

Example 3848

To set the Microsoft SQL Server version parameter by using the configuration utility 3848

Enable external health check for UDP and non-HTTP TCP virtual servers 3848

To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI 3848

To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI 3849

Content Switching for Diameter Protocol 3849

Sample Configuration 3850

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Protecting the content switching setup against failure 3851

Configuring a backup virtual server 3851

To set up a backup content switching virtual server by using the CLI 3852

Example 3852

To set up a backup content switching virtual server by using the GUI 3853

Diverting excess traffic to a backup virtual server 3853

To configure a content switching virtual server to divert new connections to a backup virtual server by using the CLI 3853

Example 3853

To set a content switching virtual server to divert new connections to a backup virtual server by using the GUI 3854

Configuring a redirection URL 3854

To configure a redirect URL for when the content switching virtual server is unavailable by using the CLI 3854

Example 3855

To configure a redirect URL for when the content switching virtual server is unavailable by using the GUI 3855

Configuring the state update option 3855

To configure the state update option by using the CLI 3856

Example 3856

To configure the state update option by using the GUI 3856

Flushing the surge queue 3856

To flush a surge queue by using the CLI 3857

Examples 3858

To flush a surge queue by using the GUI 3858

Managing a content switching setup 3858

Unbinding policies from the content switching virtual server 3859

To unbind a policy from a content switching virtual server by using the CLI 3859

To unbind a policy from a content switching virtual server by using the GUI 3859

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Removing Content Switching Virtual Servers 3859
To remove a content switching virtual server by using the CLI 3859
To remove a content switching virtual server by using the GUI 3860
Disabling and Re-Enabling Content Switching Virtual Servers 3860
To disable or re-enable a virtual server by using the CLI 3860
To disable or re-enable a virtual server by using the GUI 3860
Renaming Content Switching Virtual Servers 3860
To rename a virtual server by using the CLI 3861
To rename a virtual server by using the GUI 3861
Managing content switching policies 3861
To modify, remove, or rename a policy by using the CLI 3861
To modify, remove, or rename a policy by using the GUI 3862
Managing client connections 3862
Redirecting Client Requests to a Cache 3863
To configure cache redirection on a virtual server by using the CLI 3863
Example 3863
To configure cache redirection on a virtual server by using the GUI 3863
Enabling Delayed Cleanup of Virtual Server Connections 3863
To configure the down state flush setting on a virtual server by using the CLI 3864
Example 3864
To configure the down state flush setting on a virtual server by using the GUI 3864
Rewriting Ports and Protocols for Redirection 3864
To configure HTTP redirection on a virtual server by using the CLI 3864
Example 3864
To configure HTTP redirection on a virtual server by using the GUI 3865
Inserting the IP Address and Port of a Virtual Server in the Request Header 3865
To insert the IP address and port of the virtual server in the client requests by using the CLI 3865
Example 3865

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To insert the IP address and port of the virtual server in the client requests by using the GUI 3866
Setting a Time-out Value for Idle Client Connections 3866
To set a time-out value for idle client connections by using the CLI 3866
Example 3866
To set a time-out value for idle client connections by using the GUI 3866
Identifying Connections with the 4-tuple and Layer 2 Connection Parameters 3867
To set the L2Conn option for a content switching virtual server by using the CLI 3867
Example 3867
To set the L2Conn option for a content switching virtual server by using the GUI 3868
Persistence support for content switching virtual server 3868
Supported persistence types on content switching virtual server 3869
Backup persistence support 3870
How persistence on content switching virtual server works 3871
Scenario 1: A content switching virtual server without persistence 3871
Scenario 2: Content switching virtual server with persistence 3872
Configure persistence type on content switching virtual server by using the CLI 3874
Configure persistence type on content switching virtual server by using the GUI 3874
Troubleshooting 3875
Resources for troubleshooting content switching 3875
Troubleshooting content switching issues 3875
DataStream 3878
How DataStream works 3878
Configure database users 3880
Add a database user by using the CLI 3880
Add a database user by using the GUI 3881
Reset the password of a database user by using the CLI 3881
Reset the password of database users by using the GUI 3881
Remove a database user by using the CLI 3881

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Remove a database user by using the GUI 3882

Configure a database profile 3882

Create a database profile by using the CLI 3882

Create a database profile by using the GUI 3883

Bind a database profile to a load balancing or content switching virtual server by using the CLI 3883

Bind a database profile to a load balancing or content switching virtual server by using the GUI 3883

Configure load balancing for DataStream 3883

Parameter values specific to DataStream 3884

Configure content switching for DataStream 3885

Parameter values specific to DataStream 3886

Configure monitors for DataStream 3887

Use Case 1: Configure DataStream for a primary/secondary database architecture 3889

To configure DataStream for a primary/secondary database setup by using the command line interface 3891

Use Case 2: Configure the token method of load balancing for DataStream 3893

Configure this example by using the CLI 3894

Configure this example by using the GUI 3895

Use Case 3: Log MSSQL transactions in transparent mode 3895

Summary of configuration tasks 3895

Configure transparent mode by using a wildcard virtual server 3896

Create a wildcard virtual server by using the CLI 3896

Create a wildcard virtual server by using the GUI 3897

Enable Use Source IP (USIP) mode globally by using the CLI 3897

Enable USIP mode globally by using the GUI 3898

Configure transparent mode by using MSSQL services 3898

Create an MSSQL service and enable USIP mode on the service by using the CLI 3898

Example 3899

Create an MSSQL service, with USIP enabled, by using the GUI 3899

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use Case 4: Database specific load balancing 3899
How database specific load balancing works 3901
Enable load balancing 3901
Enable load balancing by using the CLI 3901
Enable load balancing by using the GUI 3902
Configure a load balancing virtual server for database specific load balancing 3902
Configure a load balancing virtual server for database specific load balancing using the CLI 3902
Configure services 3903
Configure database users 3903
Add a database user by using the CLI 3903
Add a database user by using the GUI 3904
Reset the password of a database user by using the CLI 3904
Reset the password of database users by using the GUI 3904
Remove a database user by using the CLI 3904
Remove a database user by using the GUI 3905
Configure a monitor to retrieve the names of active databases 3905
Configure a monitor to retrieve the names of all the active databases hosted on a service by using the CLI 3906
Configure a monitor to retrieve the names of all the active databases hosted on a service by using the GUI 3906
Availability groups deployment support for MSSQL 3906
Sample configuration 3908
Configuration examples for MSSQL virtual server 3910
Configuration examples for MySQL virtual server 3912
DataStream reference 3913
Supported database versions, protocols, and authentication methods 3914
Character sets 3914
Transactions 3915

Special queries 3916
Audit log message support 3917
Domain Name System 3918
How DNS Works on the NetScaler 3918
Enable the ADC appliance to use DNS to resolve the host name to its respective IP address 3921
Points to note 3922
CLI configuration 3923
GUI configuration 3924
Round Robin DNS 3924
Functional Overview 3924
Round Robin DNS Example 3925
Configure DNS resource records 3925
Create SRV records for a service 3927
Add an SRV record by using the CLI 3927
Modify or remove an SRV record by using the CLI 3928
Configure an SRV record by using the GUI 3928
Create AAAA records for a domain name 3928
Add an AAAA record by using the CLI 3929
Add an AAAA record by using the GUI 3929
Create address records for a domain name 3930
Add an Address record by using the CLI 3930
Add an Address record by using the GUI 3931
Create MX records for a mail exchange server 3931
Add an MX record by using the CLI 3931
Modify or remove an MX record by using the CLI 3932
Add an MX record by using the GUI 3932
Create NS Records for an authoritative server 3932
Create an NS record by using the CLI 3932

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create an NS record by using the GUI 3933
Create CNAME records for a subdomain 3933
Add a CNAME record by using the CLI 3933
Add a CNAME record by using the GUI 3934
Cache CNAME records 3934
Create NAPTR records for telecommunications domain 3934
Create a NAPTR record by using CLI 3935
Remove a NAPTR record by using CLU 3935
Configure a NAPTR record using GUI 3935
Create PTR records for IPv4 and IPv6 addresses 3935
Add a PTR record by using the CLI 3935
Add a PTR record by using the GUI 3936
Create SOA records for authoritative information 3936
Create an SOA record by using the CLI 3936
Modify or remove an SOA record by using the CLI 3937
Configure an SOA record by using the GUI 3937
Create TXT records for holding descriptive text 3937
Create a TXT resource record by using the CLI 3938
Split the string in a TXT resource record using CLI 3938
Remove a TXT resource record by using the CLI 3939
Configure a TXT record by using the GUI 3940
Create CAA records for a domain name 3940
Add a CAA record using the CLI 3941
Add a CAA record using the GUI 3942
Create SVCB and HTTPS records for a domain name 3942
Configure SVCB and HTTPS records by using CLI 3943
Configure SVCB and HTTPS Records by using GUI 3944
Limitations 3944

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use cases 3944
Encrypted ClientHello (ECH) 3944
HTTP/2 and HTTP/3 discovery 3944
QUIC and modern transport bootstrapping 3945
Alternate and optimized service endpoints 3945
View DNS statistics 3945
View DNS records statistics by using the CLI 3945
View DNS records statistics by using the GUI 3947
Configure a DNS zone 3947
Create a DNS zone on the NetScaler appliance by using the CLI 3948
Modify or remove a DNS zone by using the CLI 3949
Configure a DNS zone by using the GUI 3949
Configure the NetScaler as an ADNS server 3949
Create an ADNS service 3951
Configure the ADNS setup to use TCP 3952
Add DNS resource records 3952
Remove ADNS services 3952
Configure domain delegation 3952
Create an SOA record 3953
Create an NS record for a name server 3953
Create an address record 3953
Create an NS record for domain delegation 3953
Create a glue record 3954
Configure NetScaler as a DNS proxy server 3954
Create a load balancing virtual server 3956
Create DNS services 3956
Bind a load balancing virtual server to DNS services 3956
Configure the DNS proxy setup to use TCP 3957

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure time-to-live values for DNS entries 3957

Specify the minimum and maximum TTL by using the CLI 3957

Specify the minimum and maximum TTL by using the GUI 3958

Flush DNS records 3959

Delete all proxy records by using the CLI 3959

Delete all proxy records by using the GUI 3959

Add DNS resource records 3959

Remove a load balancing DNS virtual server 3959

Limit the number of concurrent DNS requests on a client connection 3959

Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the CLI 3960

Specify the maximum number of concurrent DNS requests allowed on a single client connection by using the GUI 3961

DNS ECS Insertion Support 3961

Configure the ECS parameter using CLI 3961

Configure the ECS parameter using GUI 3962

Configure the NetScaler as an end resolver 3962

Enable recursive resolution 3963

Prerequisite 3964

Enable recursive resolution by using the CLI 3964

Enable DNS recursive resolution by using the GUI 3965

Enable recursive resolution in specific deployment use cases 3966

Configure the NetScaler appliance as a forwarder 3969

Add a name server 3969

Add a name server (when the NetScaler appliance acts as a forwarder) by using the CLI 3970

Add a name server (when the NetScaler appliance acts as a resolver) by using the CLI 3971

Add a name server by using the GUI 3972

Set DNS lookup priority 3972

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Set the lookup priority to DNS by using the CLI 3973

Set lookup priority to DNS by using the GUI 3973

Disable and enable name servers 3974

Enable or disable a name server by using the CLI 3974

Enable or disable a name server by using the GUI 3974

Configure NetScaler as a non-validating security aware stub-resolver 3975

Jumbo frames support for DNS to handle responses of large sizes 3975

To configure the maximum UDP packet size using the CLI 3976

To configure the maximum UDP packet size using the GUI 3976

Configure DNS logging 3977

DNS profiles 3977

DNS query logging 3978

DNS answer section logging 3978

DNS extended logging 3978

DNS error logging 3979

Policy-based logging 3979

Understand the NetScaler syslog log message format 3979

Understand the record logging format 3983

Limitations of DNS logging 3985

Configuring DNS logging 3986

Configure DNS logging for NetScaler configured as DNS Proxy by using the CLI 3987

Sample DNS logging configuration for NetScaler appliance configured as DNS proxy 3989

Sample DNS logging configuration for NetScaler appliance configured as ADNS 3990

Sample DNS logging configuration for NetScaler appliance configured as a forwarder 3991

Sample DNS logging configuration for a NetScaler appliance configured as a resolver 3991

Configure policy based logging for DNS 3992

Configure policy based logging for a DNS policy by using the CLI 3993

Configure log action for the DNS policy to log client IP address 3995

Sample DNS logging configuration for a NetScaler appliance to log client IP address 3995
Configuring DNS suffixes 3995
Create DNS suffixes 3996
Create DNS suffixes by using the CLI 3996
Create DNS suffixes by using the GUI 3997
DNS ANY query 3997
Behavior in ADNS mode 3997
Behavior in DNS proxy mode 3997
Behavior for Global Server Load Balancing (GSLB) domains 3997
Configure negative caching of DNS records 3998
Enable or disable negative caching by using the CLI 3999
Specify service or virtual server level DNS parameters by using the CLI 4000
Specify service or virtual server level DNS parameters by using the GUI 4001
Rate limiting negative response served by the appliance 4001
Rate limiting negative response served by the cache by using the CLI 4001
Rate limiting negative response served by the cache by using the GUI 4002
Cache EDNS0 client subnet data when the NetScaler appliance is in proxy mode 4002
Enable caching of ECS responses by using the CLI 4002
Limit the number of subnets that can be cached per domain by using the CLI 4003
Domain name system security extensions 4004
Configure DNSSEC 4004
Enable and disable DNSSEC 4005
Enable or disable DNSSEC by using the CLI 4005
Enable or disable DNSSEC by using the GUI 4006
Create DNS keys for a zone 4006
Create a DNS key by using the CLI 4007
Create a DNS key by using the GUI 4007
Publish a DNS key in a zone 4008

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Publish a key in a zone by using the CLI 4009
Publish a key in a DNS zone by using the GUI 4010
Configure a DNS key 4010
Configure a key by using the CLI 4010
Configure a key by using the GUI 4011
Sign and unsign a DNS zone 4011
Sign a zone by using the CLI 4011
Unsign a zone by using the CLI 4013
Sign or unsign a zone by using the GUI 4013
View the NSEC records for a given record in a zone 4014
View the NSEC record for a given record in a zone by using the CLI 4014
View the NSEC record for a given record in a zone by using the GUI 4014
Remove a DNS key 4015
Remove a key from the NetScaler by using the CLI 4015
Remove a key from the NetScaler by using the GUI 4015
Revoke a DNS key 4015
Enable revoke using CLI 4016
Enable revoke using GUI 4016
Automatic key rollover 4016
Configure automatic key rollover using CLI 4017
Configure automatic key rollover using GUI 4017
SNMP Alarm 4017
DNS Zone Transfer 4018
Enable or disable zone transfer using CLI 4018
Enable or disable zone transfer using GUI 4018
Configure DNSSEC when the NetScaler is authoritative for a zone 4018
Configure DNSSEC for a zone for which the NetScaler is a DNS proxy server 4019
Configure DNSSEC for a zone-less DNS proxy server configuration 4019

Configure DNSSEC for a partial zone ownership configuration 4020
Sign the zone on the back-end name servers 4020
Sign the partial zone on the NetScaler 4021
Configure DNSSEC for global server load balancing (GSLB) domain names 4021
Zone maintenance 4022
Re-sign an updated zone 4022
Zone Transfer in GSLB 4022
Roll over DNSSEC keys 4022
Automatic key rollover 4023
Prepublish key rollover 4023
Double signature key rollover 4025
Double-RRset 4026
Offload DNSSEC operations to the NetScaler 4028
Enable DNSSEC offloading for a zone by using the CLI 4029
Enable DNSSEC offloading for a zone by using the GUI 4030
Admin partition support for DNSSEC 4030
Supporting wildcard DNS domains 4031
Example configuration 4032
Mitigate DNS DDoS attacks 4033
Flush negative records 4034
Flush negative cache records by using the CLI 4034
Flush of negative cache records by using the GUI 4034
Protection against random subdomain and NXDOMAIN attacks 4034
Limit the memory consumed by the DNS Cache by using the CLI 4035
Limit the memory consumed by the DNS Cache by using the GUI 4035
Restrict the TTL of negative records by using the CLI 4035
Restrict the TTL of negative records by using the GUI 4036
Retain DNS records in the cache 4036

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Retain DNS records in the cache by using the CLI 4036
Retain DNS records in the cache by using the GUI 4036
Enable DNS cache bypass 4037
Enable DNS cache bypass by using the CLI 4037
Enable DNS cache bypass by using the GUI 4037
Prevent the `Slowloris` attack 4037
Limit the DNS queries to a single packet by using the CLI 4037
Limit DNS queries to a single packet by using the GUI 4038
Collect statistics of the DNS responses served from the cache 4038
Enable DNS root referral 4038
Enable root referral by using the CLI 4039
Enable root referral by using the GUI 4040
Use case: Configure the automatic DNSSEC key management feature 4040
Use case: Configure the automatic DNSSEC key management on GSLB deployment 4042
Use case: How to revoke a compromised active key 4046
Federal Information Processing Standards 4049
NetScaler 14.1 FIPS release notes 4050
VPX FIPS appliances 4051
Prerequisites 4051
Configuration 4052
Ciphers supported on a VPX FIPS appliance 4053
Upgrade a VPX FIPS appliance 4053
Limitations 4053
Troubleshooting 4054
MPX FIPS appliances 4054
Ciphers supported on MPX 8900 FIPS, MPX 9100 FIPS, MPX 9200 FIPS, and MPX 15000-50G FIPS appliances 4055
Upgrade an MPX FIPS appliance 4055

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitation 4056
Configuration 4056
Enforce strong passphrase requirements using the GUI 4057
Replace the default TLS certificate 4057
Create a Certificate Signing Request (CSR) using the GUI 4057
Disable HTTP access to the web GUI 4058
Disable local authentication and configure remote authentication using LDAP 4058
Configure remote authentication using RADIUS 4059
Configure RADIUS over TLS by using the CLI 4059
Configure RADIUS over TLS by using the GUI 4060
MPX 14000 FIPS appliances 4061
Limitations 4061
Configure the HSM 4062
Initialize the FIPS card 4062
Initialize the FIPS card by using the CLI 4063
Create a FIPS key 4065
Create a FIPS key by using the CLI 4065
Create a FIPS key by using the GUI 4066
Import a FIPS key 4067
Import a FIPS key by using the CLI 4067
Import a FIPS key by using the GUI 4067
Export a FIPS key 4068
Export a FIPS key by using the CLI 4068
Export a FIPS key by using the GUI 4069
Import an external key 4069
Import an external key as a FIPS key by using the CLI 4070
Import an external key as a FIPS key by using the GUI 4070
Configure FIPS on appliances in an HA setup 4071

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prerequisites 4071
Configure FIPS on appliances in an HA setup by using the CLI 4072
Configure FIPS on appliances in an HA setup by using the GUI 4074
Create a certificate signing request by using the CLI 4075
Create a server certificate by using the CLI 4075
Add a certificate-key pair by using the CLI 4076
Update the license on an MPX 14000 FIPS appliance 4077
Support for hybrid FIPS mode on the MPX 14000 FIPS and SDX 14000 FIPS platforms 4078
Enable hybrid FIPS mode by using the CLI 4078
Enable hybrid FIPS mode by using the GUI 4079
SDX 14000 FIPS appliances 4080
Limitations 4082
Terminology 4082
Initialize the HSM 4082
Zeroize the HSM by using the Management Service 4082
Initialize the HSM by using the Management Service 4083
Create partitions 4084
Create a partition by using the Management Service 4084
Provision a new instance or modify an existing instance and assign a partition 4085
Provision a new instance or modify an existing instance 4085
Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance 4086
Initialize the FIPS card 4087
Initialize the FIPS card by using the CLI 4087
Create a FIPS key for an instance on an SDX 14030/14060/14080 FIPS appliance 4090
Create a FIPS key by using the CLI 4090
Import a FIPS key by using the CLI 4091
Create a certificate signing request by using the CLI 4092
Create a server certificate by using the CLI 4092

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add a certificate-key pair by using the CLI 4093
Upgrade the FIPS HSM firmware on a VPX instance 4094
Upgrade the FIPS HSM firmware 4094
Support for Thales Luna Network hardware security module 4095
Supported versions matrix 4096
Prerequisites 4096
Configure a Thales Luna client on the ADC 4097
Configure Thales Luna HSMs in a high availability setup on the ADC 4101
Other ADC configuration 4105
NetScaler appliances in a high availability setup 4107
Limitations 4107
Appendix 4108
Run the script 4108
Create a certificate 4108
Copy the certificate to the HSM 4108
Copy the certificate and key from the HSM to the NetScaler appliance 4109
Use SSH to connect to the Thales Luna HSM 4109
Register the NetScaler on the Thales Luna HSM 4110
Assign the client a partition from the partition list 4110
Register the HSM with its certificate on the NetScaler 4111
Verify the network trust links (NTLs) connectivity between the ADC and HSM 4111
Save the configuration 4111
Configure automatic start of the gateway daemon at boot time 4112
FAQ 4112
Support for Azure Key Vault 4112
Architecture overview 4113
Prerequisites 4114
Configure the ADC Azure Key Vault integration 4114

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Perform the following steps on the Azure portal 4114

Perform the following steps on the ADC appliance 4115

Configure a DNS server 4115

Add and bind a root certificate 4116

Configure an Azure application 4118

Configure Azure Key Vault 4120

Add HSM key 4122

Add a certificate-key pair 4124

Bind the certificate-key pair to a virtual server 4126

Limitations 4129

FAQ 4130

When integrated with Azure Key Vault, are private keys stored in the ADC appliance memory? 4130

Is the integration FIPS 140-2 level 2 compliant? 4130

Which key types are supported? 4130

What key sizes are supported? 4130

Which ciphers are supported? 4130

Are transactions logged? 4130

What is the advantage of implementing NetScaler integration with Azure Key Vault? 4131

By configuring the NetScaler Azure Key Vault integration, can I place individual server certificates in the Azure Key Vault and not install individual server certificates in NetScaler? 4131

What all certificates do I need to bind to the virtual server? 4131

If a content switching virtual server is configured, does the SSL handshake happen twice with Azure Key Vault since the same certificate is bound to content switching virtual server and load balancing virtual server? 4132

Is it mandatory to configure HSM? 4132

NetScaler® FIPS FAQ 4132

General Overview 4132

What is the Federal Information Processing Standard (FIPS)? 4132

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Form factor and series options 4133

What are the current FIPS options for NetScaler? 4133

Which NetScaler appliances are FIPS validated? 4134

Why did NetScaler develop its own cryptographic modules for FIPS validation? 4135

Is FIPS 140-3 level 2 more secure than FIPS 140-2 Level 3? 4135

Is NetScaler trading off security over performance by having MPX 9100 FIPS and MPX 9200 FIPS at Level 2? 4135

FIPS Encryption/Ciphers 4136

Which ciphers are supported on NetScaler MPX 8900/9100/9200 FIPS and VPX FIPS? 4136

What key sizes are supported in the VPX FIPS and MPX 8900/9100/9200 FIPS series? 4136

What happens if I try to add non-compliant ciphers to my virtual servers that are using a certificate to enable FIPS encryption? 4136

Features and Functions 4136

Does NetScaler FIPS include all the standard NetScaler functionality? 4136

Upgrading NetScaler firmware 4136

How do I know which firmware is compatible with my NetScaler? 4137

Can I upgrade to a FIPS validated version firmware from a non-FIPS version of firmware? 4138

How do I upgrade firmware on my FIPS validated appliances? 4138

Can VPX FIPS be installed on NetScaler SDX or NetScaler SDX FIPS appliances? 4138

Can we upgrade or downgrade VPX to VPX FIPS or vice versa? 4138

Firmware information and differences 4138

Can the FIPS validated build be installed on the MPX series other than MPX 8900 FIPS, MPX 9100 FIPS, and MPX 9200 FIPS? 4138

Can I deploy NetScaler FIPS appliances in a high-availability deployment? 4139

Can I deploy a NetScaler FIPS Cluster 4139

Will the NetScaler MPX 14000 FIPS commands work on NetScaler MPX 8900/9100/9200 FIPS appliances? 4139

Do VPX FIPS and MPX 8900/9100/9200 FIPS support Admin Partitions? Are there any differences from non-FIPS appliances? 4139

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Which NetScaler appliances require specific firmware, and why? 4139

Pooled Licensing 4140

Is Pooled licensing supported on NetScaler MPX 8900/9100/9200 and NetScaler VPX FIPS appliances? 4140

VPX FIPS 4140

Which hypervisors are supported for NetScaler VPX FIPS? 4140

What are the prerequisites to run a NetScaler VPX FIPS appliance? 4140

How is NetScaler VPX FIPS packaged? 4140

Where can I find NetScaler FIPS documentation? 4141

Are there advantages to operating an instance in non-FIPS mode on a NetScaler SDX FIPS appliance? 4141

Performance 4141

Why are instances or appliances configured to use FIPS mode not able to achieve the same TPS rates for SSL traffic as the non-FIPS counterparts? 4141

Cloud 4142

How do I get FIPS compliance in the Azure Cloud? 4142

How can I tell if my NetScaler appliance is operating in FIPS mode? 4142

Configure and manage GSLB service groups by using the CLI 4276
Enable or disable GSLB service group members 4278
Changes to the existing GSLB CLI commands 4279
Configure GSLB service groups by using the GUI 4280
Configure site persistence for the GSLB service groups 4280
To set site persistence based on HTTP cookies by using the CLI 4280
To set site persistence based on cookies by using the GUI 4281
To change the GSLB site of a GSLB service group using CLI 4282
To change the GSLB site of a GSLB service group using GUI 4282
Configure a GSLB virtual server 4282
To create a GSLB virtual server by using the command line interface 4283
To modify or remove a GSLB virtual server by using the command line interface 4283
To configure a GSLB virtual server by using the configuration utility 4284
To view the statistics of a GSLB virtual server by using the command line interface 4284
To view the statistics of a GSLB virtual server by using the configuration utility 4284
GSLB virtual server statistics 4284
GSLB service statistics 4286
Clearing the GSLB virtual server or service statistics 4287
To clear the statistics of a GSLB virtual server by using the command line interface 4287
To clear the statistics of a GSLB service by using the command line interface 4287
To clear the statistics of a GSLB virtual server by using the configuration utility 4287
To clear the statistics of a GSLB service by using the configuration utility 4288
Enabling and Disabling GSLB Virtual Servers 4288
To enable or disable a GSLB virtual server by using the command line interface 4288
To enable or disable a GSLB virtual server by using the configuration utility 4288
Use cases - GSLB virtual server 4288
Bind GSLB services to a GSLB virtual server 4289
To bind a GSLB service to a GSLB virtual server by using the command line interface 4289

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To unbind a GSLB service from a GSLB virtual server by using the command line interface 4289
To bind GSLB services by using the configuration utility 4289
Bind a domain to a GSLB virtual server 4290
To bind a domain to a GSLB virtual server by using the command line interface 4290
To unbind a GSLB domain from a GSLB virtual server by using the command line interface 4290
To bind a domain to a GSLB virtual server by using the configuration utility 4290
To view the statistics of a domain by using the command line interface 4291
To view the statistics of a domain by using the configuration utility 4291
To view the configuration details of the entities bound to a GSLB domain using the command line 4292
To view the configuration details of the entities bound to a GSLB domain by using the configuration utility 4293
Example of a GSLB setup and configuration 4294
To configure the GSLB setup with NetScaler appliances by using the CLI commands 4295
Synchronize the configuration in a GSLB setup 4296
To improve the time taken for configuration synchronization on all GSLB sites 4298
Limitations of synchronization 4298
Points to note before starting the synchronization of a GSLB setup 4299
Manual synchronization between sites participating in GSLB 4300
Points to note 4300
Previewing GSLB synchronization 4303
Debugging the commands triggered during synchronization process 4303
GSLB location file synchronization 4304
To enable the GSLB location file synchronization using the CLI 4304
To enable the GSLB location file synchronization using the GUI 4304
Real-time synchronization between sites participating in GSLB 4304
Best practices for using the real-time synchronization feature 4305
To enable real-time synchronization by using the CLI 4305

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable real-time synchronization by using the GUI 4307
Points to note 4308
Incremental synchronization of GSLB configuration 4309
To enable GSLB configuration incremental synchronization by using the CLI 4310
To enable GSLB incremental synchronization by using the GUI 4310
Full synchronization of GSLB configuration 4310
To enable GSLB full synchronization by using the CLI 4311
Multiple main sites in a GSLB deployment 4312
View GSLB synchronization status and summary 4312
To view the GSLB synchronization status or summary by using the CLI 4312
Sample configuration output for GSLB manual synchronization 4313
Sample configuration output for GSLB real-time synchronization 4313
To view the GSLB synchronization status or summary by using the GUI 4317
SNMP traps for GSLB configuration synchronization 4317
Sample SNMP trap messages 4318
Secure GSLB configuration synchronization 4319
Limitations 4319
Configure the KRPC channel by using the CLI 4319
Configure the KRPC channel by using the GUI 4319
Source IP address whitelisting for GSLB communication channels 4320
Source IP address specification 4320
Enforcement and dataset binding 4320
Dataset requirements 4321
Source IP address specification enforcement 4321
Benefits 4321
Configure the Source IP address whitelisting feature by using the CLI 4321
Enable Source IP address whitelisting 4321
Bind authorized IP addresses to the whitelist dataset 4322

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Verify configuration status 4322
Enable Source IPaddress whitelisting by using the GUI 4322
GSLB dashboard 4322
Monitor GSLB services 4322
Configure monitor trigger 4323
To configure monitor triggering by using the command line interface 4323
To configure monitor triggering by using the configuration utility 4324
Add or remove monitors 4324
To add a monitor by using the command line interface 4324
To remove a monitor by using the command line interface 4324
To add a monitor by using the configuration utility 4324
Bind monitors to a GSLB service 4325
To bind the monitor to the GSLB service by using the command line interface 4325
To set the monitoring threshold for a GSLB service by using the command line interface 4325
To bind the monitor to the GSLB service by using the configuration utility 4326
To set the monitoring threshold for a GSLB service by using the configuration utility 4326
How domain name system supports GSLB 4326
Delegation 4327
Benefits of the hierarchical topology 4328
Resolvers 4328
Name Servers 4328
Root name servers and query resolution 4330
Recursive and non-recursive queries 4330
Caching 4331
Resource record types 4331
How GSLB supports DNS 4332
Metric exchange protocol 4335
Priority order for GSLB services 4335

Configure transition Out-Of-Service State (TROFS) in GSLB 4354

Configure dynamic weights for services 4355

To configure a GSLB virtual server to use dynamic weights by using the command line interface 4356

To set GSLB virtual server to use dynamic weights by using the configuration utility 4356

How to configure persistence in GSLB 4356

Persistence on GSLB virtual server 4357

Site persistence on GSLB services 4357

Configure persistence based on source IP address 4358

To configure persistence based on source IP address by using the CLI 4359

To configure persistence based on source IP address by using the GUI 4359

Configure site persistence based on HTTP cookies 4359

Connection Proxy 4360

HTTP redirect 4361

To set persistence based on HTTP cookies by using the CLI 4361

To set persistence based on cookies by using the GUI 4362

Manage client connections 4362

Enable delayed cleanup of virtual server connections 4362

To enable delayed cleanup of virtual server connections by using the command line interface 4362

To enable delayed cleanup of virtual server connections by using the configuration utility 4363

Manage local DNS traffic by using DNS policies 4363

DNS expressions 4363

To create an expression by using the configuration utility 4364

Configure DNS actions 4364

To configure a DNS action by using the command line interface 4365

Examples 4365

To configure a DNS action by using the NetScaler configuration utility 4366

Configure DNS policies 4367

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To add a DNS policy by using the command line interface 4369

To remove a configured DNS policy by using the command line interface 4369

To configure a DNS policy by using the NetScaler configuration utility 4370

Bind DNS policies 4370

To bind a DNS policy globally by using the command line interface 4370

To bind a DNS policy globally by using the configuration utility 4371

To view the global bindings of a DNS policy by using the command line interface 4372

To view the global bindings of a DNS policy by using the configuration utility 4372

Adding DNS Views 4372

To add a DNS view by using the command line interface 4372

To remove a DNS view by using the command line interface 4373

To add a DNS view by using the configuration utility 4373

Configure GSLB for proximity 4373

Configure dynamic round trip time (RTT) method 4373

Configure static proximity 4374

Configure static proximity and dynamic RTT 4375

Protect the GSLB setup against failure 4375

Configure a backup GSLB virtual server 4375

To configure a backup GSLB virtual server by using the command line interface 4376

To set GSLB virtual server as a backup virtual server by using the configuration utility 4376

Configure a GSLB setup to respond with multiple IP addresses 4376

To configure a GSLB virtual server for multiple IP responses by using the command line interface 4377

To set a GSLB virtual server for multiple IP responses by using the configuration utility 4377

Configuring a GSLB Virtual Server to Respond with an Empty Address Record When DOWN 4377

To configure a GSLB virtual server for empty down responses by using the command line interface 4378

To set a GSLB virtual server for empty down responses by using the configuration utility 4378

Configure a backup IP address for a GSLB domain 4378

To set a backup IP address for a domain by using the command line interface 4378

To set a backup IP address for a domain by using the configuration utility 4379

Divert excess traffic to a backup virtual server 4379

To configure backup GSLB virtual server by using the command line interface 4381

To configure backup GSLB virtual server by using the configuration utility 4381

Configure GSLB for disaster recovery 4381

Configure GSLB for disaster recovery in an active-standby data center setup 4382

To designate the standby GSLB site by using the command line interface 4382

To configure the standby site by using the configuration utility 4383

Configure for disaster recovery in an active-active data center setup 4383

Configuring for Disaster Recovery with Weighted Round Robin 4383

To configure a virtual server to assign weights to services by using the command line interface 4384

To set dynamic weight by using the command line interface 4385

To add weights to the GSLB services by using the command line interface 4385

To configure a virtual server to assign weights to services by using the configuration utility 4385

To add weights to the GSLB services by using the configuration utility 4385

To set dynamic weight by using the configuration utility 4385

Configuring for Disaster Recovery with Data Center Persistence 4386

To configure HTTP redirect by using the command line interface 4386

To configure HTTP redirect by using the configuration utility 4387

Override static proximity behavior by configuring preferred locations 4387

Example 4389

Configure GSLB service selection using content switching 4390

Sample Configuration 4391

Associate a target virtual server expression to a GSLB content switching action 4393

To configure a content switching action that specifies an expression by using the CLI 4394

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure a content switching action that specifies an expression by using the GUI 4394
Configure GSLB for DNS queries with NAPTR records 4394
NAPTR Record Format 4395
Configuration procedure 4396
Sample configuration 4396
Configure GSLB for wildcard domain 4399
To configure a GSLB setup for wildcard domain by using the CLI 4399
Use the EDNS0 client subnet option for Global Server Load Balancing 4400
Address validation 4404
To enable address validation by using the command line interface 4405
Example of a complete parent-child configuration using the metrics exchange protocol 4406
site1 4406
site1_child1 4408
site1_child2 4409
site2 4409

To create a virtual server by using the GUI 4456
Bind services to the virtual server 4457
To bind a service to a load balancing virtual server by using the CLI 4457
To bind a service to a load balancing virtual server by using the GUI 4458
Verify the configuration 4458
View the properties of a server object 4458
To view the properties of server objects by using the CLI 4458
To view the properties of server objects by using the GUI 4459
View the properties of a virtual server 4459
To view the properties of a load balancing virtual server by using the CLI 4459
To view the properties of a load balancing virtual server by using the GUI 4459
View the properties of a service 4459
To view the properties of services by using the CLI 4460
To view the properties of services by using the GUI 4460
View the bindings of a service 4460
To view the bindings of a service by using the CLI 4460
To view the bindings of a service by using the GUI 4460
View the statistics of a virtual server 4461
To display virtual server statistics by using the CLI 4461
To display virtual server statistics by using the GUI 4462
View the statistics of a service 4463
To view the statistics of a service by using the CLI 4463
To view the statistics of a service by using the GUI 4463
Load balance virtual server and service states 4463
Support for load balancing profile 4466
To create an LB profile by using the CLI 4468
To create an LB profile by using the GUI 4469
To associate an LB profile with an LB virtual server by using the CLI 4469

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To associate an LB profile with an LB virtual server by using the GUI 4471
To configure the Proximity from Self parameter in the load balancing profile by using the GUI 4471
Load balancing algorithms 4471
To set the startup round-robin factor by using the CLI 4474
To set the startup round-robin factor by using the GUI 4474
Least connection method 4474
Round robin method 4480
Least response time method 4482
Selection of services when weights are assigned 4485
To configure the least response time load balancing method by using the CLI 4487
To configure the least response time load balancing method by using the GUI 4488
LRTM method 4488
Selection of services when weights are assigned 4492
To configure the LRTM load balancing method by using the CLI 4494
To configure the LRTM load balancing method by using the GUI 4494
To enable the LRTM option in monitors by using the CLI 4494
To enable the LRTM option in monitors by using the GUI 4494
Hashing methods 4495
Consistent hashing algorithms 4497
To choose the consistent hashing algorithm by using CLI 4498
To choose the consistent hashing algorithm by using GUI 4499
The URL Hash Method 4500
The Domain Hash Method 4502
The Destination IP Hash Method 4503
The Source IP Hash Method 4503
The Source IP Destination IP Hash Method 4504
The Source IP Source Port Hash Method 4504
The Call ID Hash Method 4504

Least bandwidth method 4505
Least packets method 4509
Custom load method 4513
Static proximity method 4519
Specifying the Proximity Method 4520
To specify static proximity by using the command line interface 4520
To specify static proximity by using the GUI 4520
Token method 4521
To configure the Token load balancing method by using the command line interface 4522
To configure the token load balancing method by using the configuration utility 4523
Least requests method 4523
Configure a load balancing method that does not include a policy 4528
To set the load balancing method by using the command line interface 4528
To set the load balancing method by using the configuration utility 4529
Persistence and persistent connections 4529
About Persistence 4529
Source IP address persistence 4533
HTTP cookie persistence 4533
To change the `HTTPOnly` flag setting by using the CLI 4535
To change the `HTTPOnly` flag setting by using the GUI 4535
Encrypting the Cookie 4535
To encrypt the cookie by using the command line interface, at the command prompt, type 4535
To encrypt the cookie by using the configuration utility 4536
SSL session ID persistence 4536
Back up persistence support for SSL session ID 4536
Diameter AVP number persistence 4537
To configure Diameter-based persistence on a virtual server by using the command line interface 4537

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Custom server ID persistence 4537
To configure custom server ID persistence by using the configuration utility 4539
IP address persistence 4539
Persistence Based on Destination IP Addresses 4539
Persistence Based on Source and Destination IP Addresses 4540
SIP Call ID persistence 4540
RTSP session ID persistence 4540
Configure URL passive persistence 4541
To configure URL passive persistence by using the CLI 4542
To configure persistence on a virtual server by using the GUI 4542
Configure persistence based on user-defined rules 4542
To configure persistence based on user-defined rules by using the CLI 4544
To configure persistence based on user-defined rules by using the GUI 4544
Example: Classic Expression for a Request Payload 4544
Example: Advanced policy Expression for a Request Header 4545
Example: Advanced policy Expression for a Response Cookie 4545
Configure persistence types that do not require a rule 4545
To configure persistence on a virtual server by using the CLI 4545
To configure persistence on a virtual server by using the GUI 4546
Configure backup persistence 4546
To set backup persistence for a virtual server by using the command line interface 4547
To set backup persistence for a virtual server by using the configuration utility 4548
Configure persistence groups 4548
To create a virtual server persistency group by using the command line interface 4549
To modify a virtual server group by using the configuration utility 4550
To modify a virtual server group by using the command line interface 4550
Share persistent sessions between virtual servers 4550
Configuring Sharing of Persistent Sessions 4551

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable the useVserverPersistency parameter by using the command line interface 4551
To enable the useVserverPersistency parameter by using the GUI 4551
To designate a virtual server as a main virtual server by using the command line interface 4552
To designate a virtual server as a main virtual server by using the GUI 4552
Arguments 4552
useVserverPersistency 4552
masterVserver 4553
Example Configuration of Sharing Persistent Sessions by Using the Command Line Interface 4553
Configure RADIUS load balancing with persistence 4554
Enabling the Load Balancing or Content Switching Feature 4555
Configuring Virtual Servers 4555
To configure a load balancing virtual server by using the command line interface 4555
To configure a content switching virtual server by using the command line interface 4556
To configure a load balancing or content switching virtual server by using the configuration utility 4557
Configuring Services 4557
Binding Virtual Servers to Services 4557
Configuring a Persistency Group for Radius 4557
Configuring RADIUS Shared Secret 4557
RADIUS shared secret key validation scenarios 4557
Arguments 4558
IPaddress 4558
Radkey 4558
Message Authenticator attribute support for RADIUS Load Balancing 4560
Enable the Message-Authenticator attribute using the CLI 4560
View persistence sessions 4560
To view persistence sessions by using the command line interface 4560
To view persistence sessions by using the GUI 4561

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Clear persistence sessions 4561
To clear a persistence session by using the command line interface 4561
To clear persistence sessions by using the configuration utility 4563
Override persistence settings for overloaded services 4563
To override persistence settings for overloaded services by using the CLI 4564
Example 4564
To override persistence settings for overloaded services by using the GUI 4565
Troubleshooting 4565
Insert cookie attributes to ADC generated cookies 4567
Use case: Configure SameSite cookie attribute 4568
Configure ADC generated cookies 4568
Setting the ADC cookie attributes in the load balancing parameters by using the CLI 4569
Configure variables by using the GUI 4570
Create an assignment by using the GUI 4572
Setting the ADC cookie attributes in load balancing parameters by using the GUI 4572
Setting the ADC cookie attributes in the load balancing profile by using the CLI 4574
Setting the ADC Cookie attributes in the load balancing profile by using the GUI 4575
Verify ns variable configuration 4578
Sample output 4578
Sample configuration for inserting cookie attributes in GSLB deployment 4580
Sample configuration for inserting cookie attribute in content switching deployment 4581
Customize a load balancing configuration 4583
Customize the hash algorithm for persistence across virtual servers 4584
To change the use-port-number global setting by using the CLI 4584
To change the use-port-number global setting by using the GUI 4585
To create a new service and specify a hash identifier for a service by using the CLI 4585
To specify a hash identifier for an existing service by using the CLI 4586
To specify a hash identifier while adding a service group member 4586

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To specify a hash identifier for a service by using the GUI 4587
To specify a hash identifier for an already configured service group member by using the GUI 4588
Configure the redirection mode 4588
To configure the redirection mode by using the CLI 4588
To configure the redirection mode by using the GUI 4589
Configure per-VLAN wildcarded virtual servers 4589
To configure a wildcarded virtual server that listens to a specific VLAN by using the CLI 4589
To configure a wildcarded virtual server that listens to a specific VLAN by using the GUI 4590
Assign weights to services 4590
To configure a virtual server to assign weights to services by using the CLI 4591
To configure a virtual server to assign weights to services by using the GUI 4592
Configure the MySQL and Microsoft SQL server version setting 4592
To set the Microsoft SQL server version parameter by using the CLI 4592
Example 4592
To set the MySQL server version parameter by using the CLI 4593
Example 4593
To set the MySQL or Microsoft SQL server version parameter by using the GUI 4594
Multi-IP virtual servers 4594
Configure a multi-IP virtual server 4594
To add an IPset and bind multiple VIP addresses to it by using the CLI 4595
To bind the IPset to a virtual server by using the CLI 4595
To add an IPset and bind multiple VIP addresses to it by using the GUI 4596
To bind the IPSet to a virtual server by using the GUI 4596
GSLB support for multi-IP virtual servers 4598
Limit the number of concurrent requests on a client connection 4598
To limit the number of concurrent connections for a client by using the CLI 4599
To limit the number of concurrent connections for a client by using the GUI 4599
Configure diameter load balancing 4600

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How diameter load balancing works 4601
Load balancing diameter traffic 4602
Disconnect a session 4602
Configure load balancing for diameter traffic 4603
To configure load balancing for diameter traffic by using the command line interface 4603
To configure load balancing for Diameter traffic by using the configuration utility 4606
Configure FIX load balancing 4606
How FIX load balancing works 4606
Configure and monitor load balancing for FIX traffic 4607
To configure a FIX load balancing server by using the command line interface 4607
To configure a SSL_FIX load balancing virtual server by using the command line interface 4608
To configure a FIX service by using the command line interface 4608
To configure a SSL_FIX service by using the command line interface 4608
To configure FIXSESSION persistence by using the command line interface 4609
To set persistence timeout by using the command line interface 4609
To display FIX stats by using the command line interface 4609
To bind FIX service to FIX virtual server by using the command line interface 4610
To display FIX persistent sessions by using the command line interface 4610
To configure FIX load balancing virtual server by using the GUI 4610
To edit a FIX load balancing virtual server by using the GUI 4611
To delete a FIX load balancing virtual server by using the GUI 4611
To configure FIX Load Balancing Virtual Service by using the GUI 4611
To edit a FIX load balancing virtual service by using the GUI 4612
To delete a FIX load balancing virtual service by using the GUI 4612
To display FIX load balancing server statistics 4612
To display Persistent sessions for a FIX server by using the GUI 4612
To clear Persistent sessions for a FIX server by using the GUI 4612
MQTT load balancing 4613

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure load balancing for MQTT traffic 4614

To configure load balancing for MQTT traffic by using the CLI 4615

To configure load balancing for MQTT traffic by using the GUI 4617

MQTT message length limit 4617

Protect a load balancing configuration against failure 4618

Redirect client requests to an alternate URL 4618

To configure a virtual server to redirect the client request to a URL by using the CLI 4619

To configure a virtual server to redirect the client request to a URL by using the GUI 4620

Configure a backup load balancing virtual server 4620

To set a backup virtual server by using the CLI 4621

To set a backup virtual server by using the GUI 4622

Configure spillover 4622

Configure a predefined spillover method 4623

To configure a predefined spillover method for a virtual server by using the command line interface 4624

Example 4624

To configure a predefined spillover method for a virtual server by using the configuration utility 4624

Configure policy based spillover 4624

Configuring a Spillover Action 4625

To configure policy based spillover by using the command line interface 4625

Example 4625

Selecting an Expression for the Spillover Policy 4626

`Averagesurgecount` 4626

`Activeservices` 4626

`Activetransactions` 4626

is_dynamic_limit_reached 4626

Configuring a Spillover Policy 4627

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure a spillover policy by using the command line interface 4627
Example 4628
Binding a Spillover Policy to a Virtual Server 4628
To bind a spillover policy to a virtual server by using the command line interface 4628
Example 4629
Configuring a Backup Action for a Spillover Event 4629
To configure a backup action for spillover by using the CLI 4630
To configure a backup action for spillover by using the GUI 4631
Connection failover 4631
How connection failover works on NetScaler appliances 4632
Supported setup 4633
Features affected by connection failover 4635
To configure connection failover by using GUI 4636
To configure connection failover by using CLI 4636
To disable connection failover by using CLI 4636
To disable connection failover by using GUI 4637
Flush the surge queue 4637
To flush a surge queue by using the CLI 4638
Examples 4639
To flush a surge queue by using the GUI 4639
Manage a load balancing setup 4639
Manage server objects 4639
To enable a server by using the CLI 4640
To enable or disable a server object by using the GUI 4640
To disable a server object by using the CLI 4640
To remove a server object by using the CLI 4640
To remove a server object by using the GUI 4641
Manage services 4641

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable or disable a service by using the CLI 4641
To enable or disable a service by using the GUI 4641
Identify the cause for the service state marked DOWN by using the GUI 4642
Manage a load balancing virtual server 4642
To enable or disable a virtual server by using the CLI 4643
To enable or disable a virtual server by using the GUI 4643
To unbind a service from a virtual server by using the CLI 4643
To unbind a service from a virtual server by using the GUI 4643
Identify the cause for the virtual server state marked DOWN by using the GUI 4644
Load balancing visualizer 4645
To view load balancing virtual server properties by using the Visualizer 4646
To view configuration details for services, service groups, and monitors by using the Visualizer 4646
To view configuration details for policies and policy labels by using the Visualizer in the configuration utility 4646
To modify a resource in a load balancing configuration by using the Visualizer 4647
To add a load balancing configuration by using the Visualizer 4647
Manage client traffic 4647
Configure sessionless load balancing virtual servers 4648
Supported setup 4648
Service Types 4649
Load Balancing Methods 4649
Limitations 4649
To add a sessionless virtual server by using the CLI 4650
To configure sessionless load balancing on an existing virtual server 4651
Example 4651
To configure a sessionless virtual server by using the GUI 4651
Redirect HTTP requests to a cache 4651

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure cache redirection on a virtual server by using the CLI 4652

To configure cache redirection on a virtual server by using the GUI 4652

Enable cleanup of virtual server connections 4652

To configure the down state flush setting on a virtual server by using the CLI 4654

To configure the down state flush setting on a virtual server by using the GUI 4654

Rewrite ports and protocols for HTTP redirection 4654

To configure HTTP redirection on a virtual server by using the CLI 4659

To configure HTTP redirection on a virtual server by using the GUI 4659

To configure SSL Redirect on an SSL virtual server or service by using the CLI 4659

To configure SSL redirection and SSL port rewrite on an SSL virtual server or service by using the GUI 4659

Insert IP address and port of a virtual server in the request header 4660

To insert the IP address and port of the virtual server in the client requests by using the CLI 4660

To insert the IP address and port of the virtual server in the client requests by using the GUI 4660

Use a specified source IP for back-end communication 4661

Usage of a net profile for sending traffic 4662

Manage net profiles 4663

Create an IP set 4663

To create an IP set by using the CLI 4664

Examples 4664

To create an IP set by using the GUI 4666

Create a net profile 4666

To create a net profile by using the CLI 4666

Examples 4667

Bind a net profile to a NetScaler entity 4667

To bind a net profile to a server by using the command line interface 4667

Examples 4668

To bind a net profile to a virtual server by using the GUI 4668

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind a net profile to a service by using the CLI 4668
Example 4668
To bind a net profile to a service by using the GUI 4668
To bind a net profile to a service group by using the CLI 4669
Example 4669
To bind a net profile to a service group by using the GUI 4669
To bind a net profile to a monitor by using the CLI 4669
Example 4669
To bind a net profile to a monitor by using the GUI 4669
Set a time-out value for idle client connections 4669
To set a time-out value for idle client connections by using the CLI 4670
To set a time-out value for idle client connections by using the GUI 4670
Manage RTSP connections 4670
To configure RTSP NAT by using the CLI 4671
To configure RTSP NAT by using the GUI 4671
Manage client traffic based on traffic rate 4671
Identify a connection with layer 2 parameters 4671
To configure the L2 connection option by using the CLI 4672
Example 4672
To configure the L2 connection option by using the GUI 4672
Configure the Prefer Direct Route option 4672
To set the Prefer Direct Route option by using the CLI 4673
To set the Prefer Direct Route option by using the GUI 4673
Use a source port from a specified port range for back-end communication 4673
To specify a source port range or ranges by using the CLI 4674
To specify a source port range or ranges by using the GUI 4674
Sample Configuration 4674
Configure source IP persistency for back-end communication 4675

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable source IP persistency in a net profile by using the CLI 4675
To enable source IP persistency in a net profile by using the GUI 4676
Example 4676
Use IPv6 link local addresses on the server side of a load balancing setup 4677
Advanced load balancing settings 4678
Gradually step up the load on a new service with virtual server–level slow start 4679
Manual slow start 4680
Automated slow start 4681
Set the slow start parameters 4684
To configure stepwise load increments for a new service by using the command line interface 4684
Example 4685
To configure stepwise load increments for a new service by using the configuration utility 4685
The no-monitor option for services 4686
To set the no-monitor option for a new service by using the CLI 4686
To set the no-monitor option for an existing service by using the CLI 4688
To set the no-monitor option for a service by using the GUI 4690
Protect applications on protected servers against traffic surges 4690
To set surge protection on the service by using the CLI 4690
To set surge protection on the service by using the GUI 4690
Enable cleanup of virtual server and service connections 4691
To set down state flush on the service by using the CLI 4692
To set down state flush on the service by using the GUI 4693
To set down state flush on the virtual server by using the CLI 4693
To set down state flush on the virtual server by using the GUI 4693
Graceful shutdown of services 4693
Adding a TROFS Code or String 4694
To configure a TROFS code or string in a monitor by using the command line interface 4694
To modify the TROFS code or string by using the command line interface 4694

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure a TROFS code or string in a monitor by using the configuration utility 4695
Disabling a Service 4695
To configure graceful shutdown for a service by using the command line interface 4696
To configure graceful shutdown for a service by using the configuration utility 4698
Enable or disable persistence session on TROFS services 4698
To set the trofsPersistence flag by using the command line interface 4699
Argument 4699
Direct requests to a custom webpage 4700
To set SureConnect on the service by using the CLI 4700
To set SureConnect on the service by using the GUI 4700
Enable access to services when down 4700
To enable access down on a service by using the CLI 4701
To enable access down on a service by using the GUI 4701
Enable TCP buffering of responses 4701
To enable TCP Buffering on a service by using the CLI 4701
To enable TCP Buffering on a service by using the GUI 4701
Enable compression 4702
To enable compression on a service by using the CLI 4702
To enable compression on a service by using the GUI 4702
Enable external health check for UDP and non-HTTP virtual servers 4702
To enable external health check for UDP and non-HTTP TCP virtual servers by using CLI 4703
To enable external health check for UDP and non-HTTP TCP virtual servers by using GUI 4703
Maintain client connection for multiple client requests 4704
To enable the client keep-alive on a service by using the CLI 4704
To enable the client keep-alive on a service by using the GUI 4704
Insert the IP address of the client in the request header 4704
To insert the client IP address in the client request by using the CLI 4705
To insert the client IP address in the client request by using the GUI 4705

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Retrieve location details from user IP address using geolocation database 4705

Getting user location details using geolocation functions 4706

Setting up geolocation database 4706

Geolocation functions 4706

Configuring geolocation functions 4707

Enable load balancing, responder, rewrite features 4707

Use case 1: Configuring geolocation function for redirecting invalid users outside geo location 4707

Add responder action 4708

Add audit log message action 4708

Add responder policy 4708

Bind responder policy to load balancing server 4709

Use case 2: Configuring geolocation function for inserting new HTTP header with location details for back-end to respond 4709

Add rewrite action 4709

Add rewrite policy 4710

Bind rewrite policy to load balancing 4710

Syslog support for logging geolocation details (optional) 4710

Output for user geolocation details 4711

Use the source IP address of the client when connecting to the server 4711

To enable USIP mode for a service by using the CLI 4711

To enable USIP mode for a service by using the GUI 4711

Use client source IP address for back end communication in a v4-v6 load balancing configuration 4712

Configuration Steps 4712

Sample configuration 4713

Configure the source port for server-side connections 4714

Configure the use proxy port setting on a service 4715

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure the Use Proxy Port setting on a service by using the CLI 4715
To configure the Use Proxy Port setting on a service by using the GUI 4716
Configure the use proxy port setting globally 4716
To configure the Use Proxy Port setting globally by using the CLI 4716
To configure the Use Proxy Port setting globally by using the GUI 4717
Set a limit on the number of client connections 4717
To set a limit to the number of client connections by using the CLI 4717
To set a limit to the number of client connections by using the GUI 4717
Set a limit on the number of requests per connection to the server 4717
To limit the number of client requests per connection by using the CLI 4718
To limit the number of client requests per connection by using the GUI 4718
Set a threshold value for the monitors bound to a service 4718
To set the monitor threshold value on a service by using the CLI 4719
To set the monitor threshold value on a service by using the GUI 4719
Set a timeout value for idle client connections 4719
To set a timeout value for idle client connections by using the CLI 4719
To set a timeout value for idle client connections by using the GUI 4719
Set a timeout value for idle server connections 4720
To set a timeout value for idle server connections by using the CLI 4720
To set a timeout value for idle server connections by using the GUI 4720
Set a limit on the bandwidth usage by clients 4720
To set a maximum bandwidth limit on a service by using the CLI 4720
To set a maximum bandwidth limit on a service by using the GUI 4721
Redirect client requests to a cache 4721
To set cache redirection on a service by using the CLI 4721
To set cache redirection on a service by using the GUI 4721
Retain the VLAN identifier for VLAN transparency 4721
To configure a load balancing virtual server to retain the client VLAN ID by using the CLI 4721

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure a load balancing virtual server to retain the client VLAN ID by using the GUI 4722
Configure automatic state transition based on percentage health of bound services 4722
To configure percentage based automatic state transition by using the CLI 4722
To configure percentage based automatic state transition by using the GUI 4723
To enable the ENTITY-STATE alarm by using the CLI 4723
To enable the ENTITY-STATE alarm by using the GUI 4723
Static proximity based on NetScaler location 4723
Prerequisite 4723
To configure the proximityFromSelf parameter by using the CLI 4724
To configure the Proximity from Self parameter by using the GUI 4724
Built-in monitors 4724
TCP-based application monitoring 4725
To configure TCP-based monitors by using CLI 4726
SSL service monitoring 4727
Sample configuration for HTTP-ECV health check monitor 4728
Bind a monitor to a service by using the GUI 4729
Create and bind a monitor to a service by using the CLI 4729
HTTP/2 service monitoring 4729
Bind the HTTP/2 monitor to a service by using the CLI 4730
Proxy protocol service monitoring 4730
Configure proxy protocol monitor by using the CLI 4732
FTP service monitoring 4733
To send secure FTP probes to FTP services by using the CLI 4734
To send secure FTP probes to FTP services by using the GUI 4734
Secure monitoring of servers by using SFTP 4734
To configure secure monitoring using SFTP by using the CLI 4734
To configure secure monitoring using SFTP by using the GUI 4735
Set SSL parameters on a secure monitor 4735

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Monitor Types that Support SSL Profiles 4735

To specify an SSL profile while adding a monitor by using the command line 4736

To bind a certificate-key pair to a monitor by using the command line 4736

SIP service monitoring 4736

To configure SIP service monitoring using the CLI 4737

To configure SIP service monitoring using the GUI 4737

RADIUS service monitoring 4737

Monitor accounting information delivery from a RADIUS server 4739

To configure a RADIUS accounting monitor by using the command line interface 4739

Example 4740

DNS and DNS-TCP service monitoring 4740

LDAP service monitoring 4741

Configure the LDAP monitor by using CLI 4741

MySQL service monitoring 4742

To configure MySQL monitors by using CLI 4742

SNMP service monitoring 4743

NNTP service monitoring 4743

POP3 service monitoring 4744

To configure POP3 monitors by using CLI 4745

SMTP service monitoring 4745

RTSP service monitoring 4745

ARP request monitoring 4750

Citrix Virtual Desktops™ Delivery Controller service monitoring 4751

To add an XD-DDC monitor with the validate credentials option by using the command line interface 4752

To specify the validate credentials option on an XD-DDC monitor by using the command line interface 4753

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure an XD-DDC monitor with the validate credentials option by using the configuration utility 4753

Citrix® StoreFront™ stores monitoring 4754

Create a StoreFront monitor by using the CLI 4754

Example 4755

Create a StoreFront monitor by using the GUI 4755

Extended StoreFront monitor 4756

Configure the extended StoreFront monitor by using the GUI 4757

Configure the extended StoreFront monitor by using the CLI 4757

Error messages 4757

Oracle ECV service monitoring 4761

Unsupported security features 4761

Custom monitors 4761

Configure HTTP-inline monitors 4762

To configure HTTP-inline monitors by using CLI 4762

Understand user monitors 4763

How to use a user monitor to check websites 4771

Understand the internal dispatcher 4772

Configure user monitor 4774

To configure a user monitor by using the CLI 4775

To configure a user monitor by using the GUI 4776

Understand load monitors 4777

Configure load monitors 4779

To create a metric table by using the command line interface 4779

To create a metric table and bind metrics to it by using the configuration utility 4779

Unbind metrics from a metrics table 4779

To unbind metrics from a metric table by using the command line interface 4779

To unbind metrics from a metric table by using the configuration utility 4780

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure reverse monitoring for a service 4780
Configuring HTTP Reverse Monitoring for a Service 4780
To configure HTTP reverse monitoring for a service by using the CLI 4781
Configuring ICMP Reverse Monitoring for a Service 4781
To configure ICMP reverse monitoring for a service by using the CLI 4781
Configuring TCP Reverse Monitoring for a Service 4782
To configure TCP reverse monitoring for a service by using the CLI 4782
To configure reverse monitoring by using the GUI 4782
Configure monitors in a load balancing setup 4782
Create monitors 4784
To create a monitor by using the CLI 4784
To create a monitor by using the GUI 4784
Configure monitor parameters to determine the service health 4786
Retries 4786
failureRetries 4786
alertRetries 4786
Setting alertRetries to a value higher than the Retries value 4786
To set the alertRetries parameter value to a higher value than the Retries value by using the command line interface 4787
To set the alertRetries parameter value to a higher value than the Retries value by using the GUI 4787
Bind monitors to services 4787
To bind a monitor to a service by using the CLI 4788
To bind a monitor to a service by using the GUI 4788
Modify monitors 4788
To modify an existing monitor by using the CLI 4788
To modify an existing monitor by using the GUI 4789
Enable and disable monitors 4789

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable a monitor by using the CLI 4789
To enable a monitor by using the GUI 4789
To disable a monitor by using the CLI 4789
Unbind monitors 4790
To unbind a monitor from a service by using the CLI 4790
To unbind a monitor from a service by using the GUI 4790
Remove monitors 4790
To remove a monitor by using the CLI 4790
To remove a monitor by using the GUI 4791
View monitors 4791
To view monitor bindings by using the CLI 4791
To view monitor bindings by using the GUI 4791
To view monitors by using the CLI 4791
To view monitors by using the GUI 4792
Close monitor connections 4792
Closing Monitor Connections at the Service or Service Group Level 4792
To configure monitor-connection closure at the service level by using the CLI 4793
To configure monitor-connection closure at the service group level by using the CLI 4793
To configure monitor-connection closure at the service level by using the GUI 4793
To configure monitor-connection closure at the service group level by using the GUI 4793
Ignore the upper limit on client connections for monitor probes 4794
To set the Skip MaxClients for Monitor Connections option by using the CLI 4794
To set the Skip MaxClients for Monitor Connections option by using the GUI 4794
Manage a large scale deployment 4794
Ranges of virtual servers and services 4795
Creating a range of virtual servers 4796
To create range of virtual servers by using the CLI 4796
To create range of virtual servers by using the CLI 4796

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create range of virtual servers by using the GUI 4797

Creating a range of services 4797

To create range of services by using the CLI 4797

Configure service groups 4798

Create service groups 4799

To create a service group by using the command line 4799

To create a service group by using the configuration utility 4799

Bind a service group to a virtual server 4799

To bind a service group to a virtual server by using the command line interface 4799

To bind a service group to a virtual server by using the GUI 4799

Bind a member to a service group 4800

To add members to a service group by using the command line interface 4800

To add members to a service group by using the configuration utility 4800

Bind a monitor to a service group 4801

To bind a monitor to a service group by using the command line interface 4801

To a bind monitor to a service group by using the configuration utility 4801

Retain the original state of a service group member after disabling and enabling a virtual server 4802

Manage service groups 4802

Modify a service group 4802

To modify a service group by using the command line interface 4802

To modify a service group by using the configuration utility 4803

Remove a service group 4803

To remove a service group by using the command line interface 4803

To remove a service group by using the configuration utility 4803

Unbind a member from a service group 4804

To unbind members from a service group by using the command line interface 4804

To unbind members from a service group by using the configuration utility 4804

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Unbind a service group from a virtual server 4804

To unbind a service group from a virtual server by using the command line interface 4804

To unbind a service group from a virtual server by using the configuration utility 4805

Unbind monitors from service groups 4805

To unbind a monitor from a service group using the command line interface 4805

To unbind a monitor from a service group by using the configuration utility 4805

Enable or Disable a service group 4805

To disable a service group by using the command line interface 4806

To disable a service group by using the configuration utility 4806

To enable a service group by using the command line interface 4806

To enable a service group by using the configuration utility 4806

View the status of service groups members 4806

Viewing the properties of a service group 4807

To view the properties of a service group by using the command line interface 4807

To view the properties of a service group by using the configuration utility 4808

Viewing service group statistics 4808

To view the statistics of a service group by using the command line interface 4808

To view the statistics of a service group by using the configuration utility 4808

Load balancing virtual servers bound to a service group 4809

To display the virtual servers bound to a service group by using the command line interface 4809

To display the virtual servers bound to a service group by using the configuration utility 4810

Configure a desired set of service group members for a service group in one NITRO API call 4810

Use case: Synchronize deployment changes to NetScaler appliance in large scale deployments, such as Kubernetes 4811

Create a service group of type API by using the CLI 4811

Arguments 4812

autoDisablegraceful 4812

autoDisabledelay 4813

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Autoscale API 4813
Unbind a service group member gracefully 4814
Create a service group of type API by using the GUI 4815
Configure graceful shutdown or a time delay for an API type service group by using the GUI 4815
Configure automatic domain based service group scaling 4816
To configure a service group to scale automatically by using the command line interface 4817
Example 4817
To configure a service group to scale automatically by using the configuration utility 4819
Overwriting TTL values 4820
Overwriting the TTL values using the CLI 4820
Overwriting the TTL values using the GUI 4821
Specifying different name servers for service group and domain name bindings 4821
Specifying name servers while binding a server to service groups using the CLI 4822
Specifying name servers while binding a server to service groups using the GUI 4822
Auto delayed TROFS 4822
Configure auto delayed TROFS using the CLI 4823
Configure auto delayed TROFS using the GUI 4823
Service discovery using DNS SRV records 4824
Use case: Load balancing microservices 4825
Priority based load balancing using SRV records 4826
To enable querying for SRV records using the CLI 4826
To enable querying for SRV records using the GUI 4827
Create a server 4827
Create a service group with autoscale mode as DNS 4828
Bind server to the service group member 4828
Overwriting TTL values 4828
Overwriting the TTL values using the CLI 4829
Overwriting the TTL values using the GUI 4829

Specifying different name servers for service group and domain name bindings 4830
Specifying name servers while binding a server to service groups using the CLI 4830
Specifying name servers while binding a server to service groups using the GUI 4830
Translate the IP address of a domain-based server 4831
To configure a translation IP address for a server by using the command line interface 4831
To configure a translation IP address for a server by using the configuration utility 4832
Mask a virtual server IP address 4832
To configure a virtual server IP address mask by using the command line interface 4833
To configure a virtual server IP address mask by using the configuration utility 4834
Configure load balancing for commonly used protocols 4834
Load balance a group of FTP servers 4835
To create FTP monitors by using the CLI 4837
To create FTP monitors by using the GUI 4837
Load balance DNS servers 4837
To configure DNS monitors by using the CLI 4839
To configure DNS monitors by using the GUI 4840
Load balance domain-name based services 4840
To add a name server by using the command line interface 4843
To add a name server by using the configuration utility 4843
Load balance a group of SIP servers 4844
Server Initiated Traffic 4845
Support for Policies and Expressions 4845
Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP 4846
To configure a basic load balancing setup for SIP traffic by using the command line interface 4848
Sample Configuration for load balancing the SIP traffic over UDP 4851
Sample Configuration for load balancing the SIP traffic over TCP 4852
Sample Configuration for load balancing and securing SIP traffic over TCP 4854
To configure a basic load balancing setup for SIP traffic by using the GUI 4855

SIP Expression and Policy Example: Compression Enabled in Client Requests 4856
Load balance RTSP servers 4857
To configure RTSP monitors by using the CLI 4859
To configure RTSP monitors by using the GUI 4860
Load balance remote desktop protocol servers 4860
To configure RDP load balancing services by using the command line interface 4862
To configure RDP load balancing services by using the configuration utility 4863
To configure an RDP load balancing virtual server by using the command line interface 4863
To configure an RDP load balancing virtual server by using the configuration utility 4865
To configure a scripting monitor for RDP services by using the command line interface 4865
To configure a scripting monitor for RDP services by using the configuration utility 4866
Priority order for load balancing services 4866
Configure priority order for load balancing services 4867
Configure priority order for load balancing services using the CLI 4867
Configure priority order for load balancing services using the GUI 4868
Configure priority order for load balancing services using LB policy commands 4869
LB action 4869
LB policy 4870
Configure priority order for load balancing services with LB policy commands using the CLI 4871
Configure priority order for load balancing services with the LB policy commands using the GUI 4871
Persistence settings for services 4873
Priority toggle 4874
Set priority order for service group and service 4875
Use Case 1: Prioritize servers within a single service group 4875
Use case 2: Prioritize entire server farms (Multiple Service Groups) 4875
Use case 1: SMPP load balancing 4876
Introduction to SMPP 4877
Architecture Overview of the Different SMPP Entities in a Mobile Network 4877

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How SMPP Load Balancing Works on the NetScaler 4879
Messages Originating from the ESMEs 4880
Messages Originating from a Message Center 4880
Health Monitoring of Message Centers 4882
Content Switching on Message Centers 4882
Concatenated Message Handling 4883
Limitation 4884
Configuring SMPP Load Balancing on the NetScaler 4884
To configure SMPP load balancing by using the command line 4884
Example 4885
To configure SMPP load balancing by using the configuration utility 4885
Use case 2: Configure rule based persistence based on a name-value pair in a TCP byte stream 4886
Use case 3: Configure load balancing in direct server return mode 4888
To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface 4891
Example 4891
To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility 4891
To configure a service to use source IP address by using the command line interface 4892
To configure a service to use source IP address by using the configuration utility 4892
Configure a loopback interface on the backend server (Windows Server) 4892
Use case 4: Configure LINUX servers in DSR mode 4893
To configure LINUX server in DSR mode 4894
Use case 5: Configure DSR mode when using TOS 4894
To configure the redirection mode for the virtual server by using the command line interface 4896
To configure the redirection mode for the virtual server by using the configuration utility 4896
To configure the transparent monitor for TOS by using the command line interface 4897

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create the transparent monitor for TOS by using the configuration utility 4897
Wildcard TOS Monitors 4897
To create a wildcard TOS monitor by using the CLI 4898
To bind a wildcard TOS monitor to a service by using the CLI 4898
To create a wildcard TOS monitor by using the GUI 4898
To bind a wildcard TOS monitor to a service by using the GUI 4899
Use case 6: Configure load balancing in DSR mode for IPv6 networks by using the TOS field 4902
To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance 4904
To configure load balancing in DSR Mode using TOS by using the command line interface 4904
To enable USIP mode by using the configuration utility 4905
To create services by using the configuration utility 4905
To create a load balancing virtual server and bind services by using the configuration utility 4905
Use case 7: Configure load balancing in DSR mode by using IP Over IP 4905
Configure a load balancing virtual server 4906
To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface 4906
To create and configure a load balancing virtual server for IP over IP DSR by using the GUI 4907
Configure services for IP over IP DSR 4907
To create and configure a service for IP over IP DSR by using the command line interface 4907
To configure a monitor by using the GUI 4908
To create and configure a service for IP over IP DSR by using the GUI 4908
To bind a service to a load balancing virtual server by using the command line interface 4909
To bind a service to a load balancing virtual server by using the GUI 4909
Using the client IP address in the Outer header of tunnel packets 4909
To use a client-source IP address as the source IP address by using the CLI 4909
To use client source IP address as the source IP address by using the GUI 4910
To use client source IP address as the source IP address by using the CLI 4910

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To use client source IP address as the source IP address by using the GUI 4910

Decapsulation configuration 4910

NetScaler decapsulation 4910

Back-end server decapsulation 4913

Use case 8: Configure load balancing in one-arm mode 4916

Use case 9: Configure load balancing in the inline mode 4917

Use case 10: Load balancing of intrusion detection system servers 4918

To enable MAC-based forwarding by using the command line interface 4921

To enable MAC-based forwarding by using the configuration utility 4921

To configure a load balancing method and redirection mode for a sessionless virtual server by using the command line interface 4922

To configure a load balancing method and redirection mode for a sessionless virtual server by using the configuration utility 4922

To set a service to use the source IP address by using the command line interface 4923

To set a service to use the source IP address by using the configuration utility 4923

Use case 11: Isolating network traffic using listen policies 4923

How network paths are isolated 4925

Traffic within network domain 1 4926

Traffic between network domain 1 and network domain 2 4927

Configuration Steps 4927

To isolate network traffic by using the command line interface 4928

To isolate network traffic by using the configuration utility 4931

Use case 12: Configure Citrix Virtual Desktops™ for load balancing 4931

To configure load balancing for Citrix Virtual Desktops by using the GUI 4932

To configure load balancing for Citrix Virtual Desktops by using the command line interface 4933

Use case 13: Configure Citrix Virtual Apps™ for load balancing 4934

To configure load balancing for Citrix Virtual Apps by using the GUI 4935

To configure load balancing for Citrix Virtual Apps by using the command line interface 4936

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use case 14: ShareFile wizard for load balancing Citrix® ShareFile 4937
To configure a NetScaler appliance for load balancing Citrix ShareFile 4939
To remove load balancing configuration for ShareFile 4943
Use case 15: Configure layer 4 load balancing on the NetScaler appliance 4943
To configure layer 4 load balancing using the command line interface 4943
To configure layer 4 load balancing using the GUI 4944
Use case 16: Dual-Stack DNS server support for GSLB 4945
To configure Dual-Stack DNS server by using the CLI 4946
Example 4946
Configure autoScaling workflows in dual-stack environments 4947
Troubleshooting 4948
Resources for Troubleshooting Load Balancing 4949
Troubleshooting Load Balancing Issues 4949
Load balancing FAQs 4955
What are the various load balancing policies I can create on the NetScaler appliance 4955
Can I achieve the Web farm security by implementing load balancing using the NetScaler appliance? 4956
What are the various devices that I can use to load balance with a NetScaler appliance? 4956
Why do I implement the load balancing feature for the website? 4956
Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)? 4957
Networking 4958
IP Addressing 4958
Configuring NetScaler-owned IP addresses 4959
Configuring the NSIP address 4959
Command Line Procedures 4960
GUI Procedures 4960

Configuring and Managing Virtual IP (VIP) Addresses 4961
Detecting a NetScaler Appliance in a UDP Load Balancing Setup through TTL Updates 4966
Before You Begin 4967
Configuration Steps 4967
CLI Procedures 4967
GUI Procedures 4968
Configuring ARP response Suppression for Virtual IP addresses (VIPs) 4968
Configure ICMP response suppression for virtual IP addresses 4971
IP related configuration 4972
Configure IPv4 address with ICMP response control by using CLI 4972
Configure IPv4 address with ICMP response control by using GUI 4974
Configure IPv6 address with ICMP response control 4974
Virtual server related configuration 4976
Configure ICMP response behavior for virtual server 4976
Configuring Subnet IP Addresses (SNIPs) 4978
Using SNIPs for a Directly Connected Server Subnet 4980
Using SNIPs for Server Subnets Connected through a Router 4981
Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch 4983
Configuring GSLB Site IP Addresses (GSLBIP) 4984
Removing a NetScaler-owned IP address 4984
Configuring Application Access Controls 4985
Enable secure access to NetScaler GUI using a subnet IP address(SNIP) 4987
NetScaler CLI procedure 4988
How the NetScaler Proxies Connections 4988
How the Destination IP Address Is Selected 4988
How the Source IP Address Is Selected 4989
Enable Use Source IP Mode 4989
Before you begin 4990

RNAT 5014
Before you begin 5015
Configure RNAT 5016
CLI procedures 5016
GUI procedures 5018
Monitor RNAT 5019
Configure RNAT6 5020
CLI procedures 5021
GUI procedures 5021
Monitor RNAT6 5021
Log Start Time and Connection Closure Reasons in RNAT Log Entries 5023
Stateful Connection Failover for RNAT 5025
Reserving the source port for RNAT connections to servers 5025
Removing RNAT Sessions 5026
Configuring Prefix-Based IPv6-IPv4 Translation 5028
IP Prefix NAT 5030
Use Case: Zonification of Clients for a Deployment of a NetScaler appliance and an Optimization Device 5030
Configuration Steps 5030
Sample configuration 5031
Static ARP 5032
Specify a VLAN in a Static ARP Entry 5033
Set the Timeout for Dynamic ARP Entries 5033
Neighbor Discovery 5034
Configuration Steps 5035
CLI procedures 5035
GUI procedures 5036
IP Tunnels 5037

Verifying the IPv6 OSPF Configuration 5226
OSPFv3 Authentication 5227
Configuring Graceful Restart for IPv6 OSPF 5228
Configuring ISIS 5230
Prerequisites for configuring ISIS 5230
Enabling ISIS 5231
Creating an ISIS Routing Process and Starting It on a VLAN 5231
Advertising Routes 5232
Limiting ISIS Propagations 5233
Verifying the ISIS Configuration 5234
Install Routes to the NetScaler Routing Table 5235
Maximum number of ECMP routes supported in a NetScaler appliance 5236
Advertisement of SNIP and VIP Routes to Selective Areas 5236
Advertise SNIP Routes to Selective Areas 5237
Advertise VIP Routes to Selective Areas 5237
Configuring Bidirectional Forwarding Detection 5238
Points to Consider for Configuring Bidirectional Forwarding Detection 5238
Configuration Steps 5239
Configure BFD Parameters 5239
Configuring BFD Parameters for a Single Hop Session 5240
Configuring BFD Parameters for IPv4 Multiple Hop Sessions 5241
Configuring BFD Parameters for IPv6 Multiple Hop Sessions 5242
Configure BFD Support for Dynamic Routing Protocols 5242
Configuring BFD for an IPv4 BGP Single Hop Session 5242
Configuring BFD for an IPv4 BGP Multiple Hop Session 5244
Configuring BFD for an IPv6 BGP Single Hop Session 5245
Configuring BFD for an IPv6 BGP Multiple Hop Session 5246
Configuring BFD for OSPFv2 (IPv4) on Interfaces 5248

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring BFD for OSPFv3 (IPv6) on Interfaces 5250
Configuring Static Routes 5251
Configuring IPv4 Static Routes 5254
Create a static route by using the CLI 5254
Create a monitored static route by using the CLI 5255
Create a null route by using the CLI 5256
Remove a static route by using the CLI 5257
Configure a static route by using the GUI 5257
Configuring IPv6 Static Routes 5257
Create an IPv6 route by using the CLI 5258
Create a monitored IPv6 static route by using the CLI 5259
Remove an IPv6 route by using the CLI 5260
Configure an IPv6 route by using the GUI 5260
Remove an IPv6 route by using the GUI 5261
Route Health Injection Based on Virtual Server Settings 5261
Configuring Policy-Based Routes 5263
Policy-Based Routes (PBR) for IPv4 Traffic 5264
Creating or modifying a PBR 5264
CLI procedures 5265
GUI procedures 5267
Applying a PBR 5268
Enabling or disabling PBRs 5268
Renumbering PBRs 5270
Use case - PBR with multiple hops 5271
Policy-Based Routes (PBR6) for IPv6 Traffic 5274
Creating or Modifying a PBR6 5274
CLI procedures 5274
GUI procedures 5275

Support for TLS1.2 signature hash algorithm 5916

Validate the peer certificate 5919

Configure a strict signature digest check on an SSL virtual server, service, or profile by using the CLI 5920

Configure SSL for ADC Admin UI access 5921

Configure secure HTTPS by using the CLI 5921

Configure secure HTTPS by using the GUI 5921

Support for TLS 1.3 protocol 5922

Supported NetScaler features 5923

Configuration 5925

Add a front-end SSL profile by using the CLI 5925

Add a front-end SSL profile by using the GUI 5928

Add a back-end SSL profile by using the CLI 5928

Add a back-end SSL profile by using the GUI 5930

Bind an SSL profile to an SSL virtual server by using the CLI 5930

Bind an SSL profile to an SSL virtual server by using the GUI 5931

Bind an SSL profile to an SSL service by using the CLI 5931

Bind an SSL profile to an SSL service by using the GUI 5931

SSL profile parameters for TLS 1.3 protocol 5932

Default cipher group 5934

Limitations 5936

Security restrictions 5936

Enhanced audit logging support for TLS Session ID and SNI 5936

Enable TLS Session and SNI Logging 5937

To enable enhanced TLS session ID and SNI logging by using CLI 5938

To enable Client Logs for Enhanced SSL Profiles (front-end and back-end) by using GUI 5938

To enable client logs for a virtual server by using GUI 5938

To enable client logs for a service by using GUI 5939

How to link an intermediate authority certificate 6030

Manual certificate linking 6030

Add a certificate set by using the CLI 6031

Add a certificate set by using the GUI 6042

Automated certificate linking 6042

Create a chain of certificates 6043

Create a certificate chain by using the CLI 6043

Create a certificate chain by using the GUI 6044

Support for SSL certificate key bundle 6044

To add a certificate key bundle using the CLI 6046

To add a certificate key bundle using the GUI 6046

To update a certificate key bundle using the CLI 6046

To update a certificate key bundle using the GUI 6046

To remove a certificate key bundle using the CLI 6047

To remove a certificate key bundle using the GUI 6047

To bind a certificate key bundle to an SSL virtual server using the CLI 6047

To bind a certificate key bundle to an SSL virtual server using the GUI 6050

To bind a certificate key bundle to an SSL virtual server as an SNI certificate key bundle using the CLI 6050

To bind a certificate key bundle to an SSL virtual server as an SNI certificate key bundle using the GUI 6053

To unbind a certificate key bundle from an SSL virtual server using the CLI 6054

To unbind a certificate key bundle from an SSL virtual server using the GUI 6054

User scenarios for certificate key bundle binding 6054

Scenario 1: A certificate-key pair and a certificate key bundle containing the same server certificate is bound to the same SSL virtual server 6055

Scenario 2: Two certificate key bundles contain the same intermediate certificate chain 6055

Scenario 2: Two certificate key bundles contain some common intermediate certificates in the chain 6056

Restrict virtual servers with a limited domain 6096

Restrict the virtual servers with a limited domain by using CLI 6096

Restrict the virtual servers with a limited domain by using the GUI 6097

Support for verbose logging in NetScaler for Zero Touch Certificate Management 6097

Logged Workflow Touchpoints 6098

Viewing ZTCM Diagnostic Logs 6098

Sample Log Messages 6098

Support for HDX or ICA Proxy virtual servers 6099

Limitations 6100

Zero touch certificate management FAQs 6100

Basic questions 6100

Is the zero touch certificate management feature recommended for customers with many appliances and thousands of SSL VIPs? 6100

Does the zero-touch certificate management feature affect performance? 6100

How is the distribution of certificates be managed? Will all certificates be available on every NetScaler®, or can we specify which certificates are distributed to particular NetScaler? 6100

Are the certificates and keys fetched by NetScaler stored only in memory, or are they also saved to the NetScaler file system? 6101

What should we do if a client does not support the SNI extension? 6101

Will it be necessary to allocate additional memory to a VPX in order to support all the certificates? 6101

Will this include certificates for SAML signing and OCSP responders? 6101

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If a customer has multiple certificates that match the SNI, which one will the NetScaler choose? Will it always prefer the most specific FQDN certificate, or the one with the longest validity period? 6101

If we enable zero touch certificate management on a NetScaler instance today, will it apply to all virtual IP addresses, including those that already have a certificate bound, or only to virtual IP addresses without SSL certificates? 6101

Does the NetScaler CLI display the certificate binding on the virtual IP addresses? Since this information does not appear in the NetScaler GUI, identifying the bindings in the CLI may assist customers with troubleshooting needs? 6102

Does NetScaler Console require any additional memory allocation? 6102

Certificate revocation using OCSP or OCSP stapling in zero touch certificate management 6102

Global zero touch OCSP parameter configuration 6103

Example modification (if necessary) 6104

SSL policy support for Per-virtual server or service control 6104

Front-end SSL handshake (client-Side) 6105

OCSP stapling 6105

Client certificate authentication OCSP validation 6106

Backend SSL handshake (server-side) 6107

Limitations 6109

SSL profiles 6110

Differences between the old and the new SSL profile infrastructure 6111

SSL profile infrastructure 6111

Points to note 6113

Save the configuration by using the CLI 6114

Enable the default profile 6115

Parameters that are part of the default profiles 6116

Use case 6120

SSL profile parameters 6122

Support for secure renegotiation at the back end of a NetScaler appliance 6122

Configure an SSL policy by using the GUI 6257
Support for SSL policies with TLS1.3 protocol 6257
Limitations 6257
SSL built-in actions and user-defined actions 6258
Examples of built-in actions in a policy 6258
Client certificate verification with policy based client authentication 6259
Set client certificate verification to optional using the CLI 6259
Set client certificate verification to optional using the GUI 6260
User-defined SSL actions 6260
Configure a user-defined SSL action by using the CLI 6260
Configure a user-defined SSL action by using the GUI 6261
Configure an SSL action to forward client traffic to another virtual server 6261
Configuration using the CLI 6262
Configuration using the GUI 6263
SSL action to selectively pick CAs based on SNI for client authentication 6264
Configuration using the CLI 6264
Configuration using the GUI 6269
Unbind a CA certificate group by using the GUI 6270
Remove a CA certificate group by using the GUI 6270
Conditional client authentication and HTTP/2 support 6270
Configure conditional client authentication and HTTP/2 6271
Configure conditional client authentication 6271
Configure conditional HTTP/2 enablement 6271
Limitation 6272
SSL policy binding 6272
Bind an SSL policy globally by using the CLI 6273
Bind an SSL policy globally by using the GUI 6274
Bind or unbind an SSL policy to a virtual server by using the CLI 6274

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bind an SSL policy to a virtual server by using the GUI 6276
SSL policy labels 6276
Create an SSL policy label and bind policies to the label by using the CLI 6277
Configure an SSL policy label and bind policies to the label by using the GUI 6278
Selective SSL logging 6278
Set DEBUG level 6279
SSL log profile 6279
Add an SSL log profile by using the CLI 6280
Add an SSL log profile by using the GUI 6282
Modify an SSL log profile by using the CLI 6282
Modify an SSL log profile by using the GUI 6283
View all the SSL log profiles by using the CLI 6283
View all the SSL log profiles by using the GUI 6284
Attach an SSL log profile to an SSL profile 6284
Attach an SSL log profile on an SSL profile by using the CLI 6285
Attach an SSL log profile to an SSL profile by using the GUI 6285
Attach an SSL log profile to an SSL action 6285
Attach an SSL log profile to an SSL action by using the CLI 6285
Attach an SSL log profile to an SSL action by using the GUI 6286
Sample output from the log file 6286
Support for DTLS protocol 6288
DTLS monitor support for DTLS service 6289
DTLS configuration 6289
Enable the DTLS protocol on DTLS virtual server by using the CLI 6290
Enable a DTLS protocol on DTLS virtual server by using the GUI 6290
Enable the DTLS v1.2 protocol on service by using the CLI 6291
Enable the DTLS v1.2 protocol on service by using the GUI 6291
Support for SNI on a DTLS virtual server 6291

Decrypting TLS1.3 traffic from packet trace 6343

CRL refresh does not happen on the secondary node in an HA setup 6343

SSL FAQs 6344

Basic questions 6344

HTTPS access to the GUI fails on a VPX instance. How do I gain access? 6344

If I add a license to an MPX appliance, the certificate-key pair binding is lost. How do I resolve this problem? 6344

What are the various steps involved in setting up a secure channel for an SSL transaction? 6344

I understand that SSL is a CPU-intensive process. What is the CPU cost associated with the SSL process? 6345

What are the various entities of an SSL configuration? 6345

I want to use the SSL offloading feature of the NetScaler appliance. What are the various options for receiving an SSL certificate? 6346

What are the minimum requirements for an SSL setup? 6346

What are the limits for the various components of SSL? 6346

What are the various steps involved in the end-to-end data encryption on a NetScaler appliance? 6347

Certificates and Keys 6347

Can I place the certificate and key files at any location? Is there any recommended location to store these files? 6347

What is the maximum size of the certificate key supported on the NetScaler appliance? 6348

What is the maximum size of the DH parameter supported on the NetScaler appliance? 6348

What is the maximum certificate-chain length, that is, the maximum number of certificates in a chain, supported on a NetScaler appliance? 6349

What are the various certificate and key formats supported on the NetScaler appliance? 6349

Is there a limit for the number of certificates and keys that I can install on the NetScaler appliance? 6349

I have saved the certificate and key files on the local computer. I want to transfer these files to the NetScaler appliance by using the FTP protocol. Is there any preferred mode for transferring these files to the NetScaler appliance? 6349

© 1997–2026 Citrix Systems, Inc. All rights reserved.

What is the default directory path for the certificate and key? 6349

When adding a certificate and key pair, what happens if I do not specify an absolute path to the certificate and key files? 6350

I have configured a high availability setup. I want to implement the SSL feature on the setup. How must I handle the certificate and key files in a high availability setup? 6350

nCipher nShield HSM 6350

When integrating with nCipher nShield HSM, do we have to keep in mind any specific configuration when adding the NetScaler appliance to HA? 6350

Do we have to individually integrate both the appliances with nCipher nShield HSM and RFS? Do we need to complete this action before or after the HA setup? 6351

Do we need to import the key into both the primary and secondary NetScaler appliances, or are the keys synchronized from the primary node to the secondary node? 6351

Given that the HSM is not on the NetScaler appliance, but on nCipher, what happens to the keys and certificates when a node fails and is replaced? 6351

Ciphers 6351

What is a NULL-Cipher? 6351

Are the NULL-Ciphers enabled by default for an SSL VIP or an SSL service? 6352

What is the procedure to remove NULL-Ciphers? 6352

What are the various cipher aliases supported on the NetScaler appliance? 6352

What is the command to display all the predefined ciphers of the NetScaler appliance? 6352

What is the command to display the details of an individual cipher of the NetScaler appliance? 6352

What is the significance of adding the predefined ciphers of the NetScaler appliance? 6353

Is it possible to change the cipher's order without unbinding them from a cipher group on a NetScaler appliance? 6353

Is ECDSA supported on the NetScaler appliance? 6353

Does the NetScaler VPX appliance support AES-GCM/SHA2 ciphers on the front-end? 6354

Certificates 6354

Is the distinguished name in a client certificate available for the length of the user session? 6354

Why do I need to bind the server certificate? 6355

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How many certificates can I bind to an SSL VIP or an SSL service? 6355

What happens if I unbind or overwrite a server certificate? 6355

How do I install an intermediate certificate on a NetScaler appliance and link to a server certificate? 6356

Why am I getting a "resource already exists" error when I try to install a certificate on the NetScaler? 6356

I want to create a server certificate on a NetScaler appliance to test and evaluate the product. What is the procedure to create a server certificate? 6356

I have received a NetScaler appliance on which NetScaler software release 9.0 is installed. I have noticed an extra license file on the appliance. Is there any change in the licensing policy starting with NetScaler software release 9.0? 6358

How do I export the certificate from the Internet Information Service (IIS)? 6358

How do I convert the PKCS#12 certificate and install it on the NetScaler? 6359

How do I convert the PKCS#7 certificate and install it on the NetScaler appliance? 6363

When I bind a cipher to a virtual server or service by using the bind cipher command, I see the error message "Command deprecated."? 6363

Why can't I create a cipher group and bind ciphers to it by using the add cipher command? 6364

OpenSSL 6364

How do I use OpenSSL to convert certificates between PEM and DER? 6364

System Limits 6365

What are the important numbers to remember? 6365

MPX 9700/10500/12500/15500 FIPS appliances 6369

HSM configuration 6370

Configure the HSM on the MPX 9700/10500/12500/15500 FIPS platform by using the CLI 6371

Configure the HSM on the MPX 9700/10500/12500/15500 FIPS platform by using the GUI 6375

Create and transfer FIPS keys 6376

Create FIPS keys 6376

Create a FIPS key by using the GUI 6376

Create a FIPS key by using the CLI 6377

How ICAP response modification (RESPMOD) works 6398
ICAP license 6398
Configure ICAP for content transformation service 6398
To enable content inspection 6398
Add ICAP profile 6398
Support for HTTP/2 in Content Inspection (ICAP Mode) 6400
Log ICAP content inspection action 6400
Add ICAP service as a TCP or SSL_TCP service 6401
Add a TCP or SSL_TCP based load balancing virtual server 6401
Bind ICAP service to the load balancing virtual server 6402
Add content inspection action 6402
Add content inspection policies 6403
Bind content inspection policies to the content switching or load balancing virtual server 6404
Configure secured ICAP service 6404
Add SSL-based TCP service to load balancing virtual server 6404
Add SSL-based TCP service to load balancing virtual server 6405
Bind SSL-based TCP service to SSL_TCP or TCP load balancing virtual server 6405
Bind SSL-based TCP service or load balancing virtual server to the Content Inspection action 6406
Configure ICAP protocol by using the GUI 6406
Configure secured ICAP protocol by using the GUI 6407
Audit log support for remote content inspection 6408
Inline device integration with NetScaler 6408
How the NetScaler is integrated with inline devices 6409
Software licensing 6410
Configuring inline device integration 6411
Scenario 1 for using a single inline device 6411
Enable MBF (MAC-based forwarding) mode 6412

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable Content Inspection 6412

Add Layer 2 connection method 6412

Add Content Inspection profile for service 6412

Add IPS-TCP monitor 6413

Add a service 6413

Add a health monitor 6413

Bind the service to the health monitor 6414

Add content inspection action for service 6414

Add content inspection policy for inspection 6415

Add content switching or load balancing virtual server of type HTTP/SSL 6415

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL 6415

Scenario 2: Load balancing multiple inline devices using dedicated interfaces 6416

Add content inspection profile1 for service1 6416

Add content inspection profile2 for service2 6417

Add service 1 for inline device 1 6417

Add service 2 for inline device 2 6417

Add load balancing virtual server 6418

Bind service 1 to the load balancing virtual server 6418

Bind service 2 to the load balancing virtual server 6418

Add content inspection action for the service 6419

Add content inspection policy for inspection 6419

Add content switching or load balancing virtual server of type HTTP/SSL 6419

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL 6420

Scenario 3: Load balancing multiple inline devices using shared interfaces 6420

Bind VLAN A with sharing option enabled 6421

Bind VLAN B with sharing option enabled 6421

Bind VLAN C with sharing option enabled 6421

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bind VLAN D with sharing option enabled 6422

Add content inspection profile1 for service1 6422

Add content inspection profile2 for service2 6422

Configure inline service integration using the NetScaler GUI 6423

Integration with IPS or NGFW as inline devices using SSL forward proxy 6425

SSL forward proxy integration with inline devices 6426

Configuring inline device integration 6427

Scenario 1: Using a single inline device 6427

Configure using the CLI 6428

Configure using the GUI 6431

Configure using the CLI 6432

Configuration using the GUI 6435

Scenario 3: Load balance multiple inline devices with shared interfaces 6436

Configuration using the CLI 6436

Configuration using the GUI 6439

Integrating NetScaler with passive security devices (Intrusion Detection System) 6440

How NetScaler is integrated with IDS device with L2 connectivity 6441

Software licensing 6443

Configuring intrusion detection system integration 6443

Scenario 1: Integration with a single IDS device 6443

Enable Content Inspection 6443

Add Content Inspection profile of type "MIRROR 6444

Add IDS service 6444

Add content inspection action of type MIRROR for IDS service 6444

Add content inspection policy for IDS inspection 6445

Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL 6445

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bind Content Inspection policy to content switching virtual server or load balancing virtual server of type HTTP/SSL 6445

Scenario 2: Load balancing multiple IDS devices 6446

Add content inspection profile1 of type MIRROR for IDS service 1 6447

Add content inspection profile 2 for type MIRROR for IDS service 2 6447

Add IDS service 1 of type ANY for IDS device 1 6447

Add IDS service 2 of type ANY for IDS device 2 6448

Add load balancing virtual server 6448

Bind IDS service 1 to load balancing virtual server 6449

Bind IDS service 2 to load balancing virtual server 6449

Add content inspection action for the IDS service 6449

Add content inspection policy for inspection 6449

Add content switching or load balancing virtual server of type HTTP/SSL 6450

Bind Content Inspection policy to load balancing virtual server of type HTTP/SSL 6450

Configure inline service integration using the NetScaler GUI 6450

Integrating NetScaler layer 3 with passive security devices (Intrusion Detection System) 6452

How NetScaler is integrated with IDS device with L3 connectivity 6453

Software licensing 6454

Configuring intrusion detection system integration 6454

Scenario 1: Integration with a single IDS device 6454

Enable Content Inspection 6455

Add Content Inspection profile of type “MIRROR" 6455

Add IDS service 6455

Add content inspection action of type MIRROR for IDS service 6456

Add content inspection policy for IDS inspection 6456

Bind content inspection policy to content switching or load balancing virtual service of type HTTP/SSL 6456

Unified configuration file for NetScaler 6609
Sample output 6610
System user authentication and authorization 6613
User, user groups, and command policies 6613
Configure user accounts 6615
Configure a user account by using the NetScaler GUI 6616
Configure user groups 6618
To create a user group by using the command line interface 6618
Bind a user account to a group by using the CLI 6618
Configure a user group by using the NetScaler GUI 6618
Configure command policies 6620
Create custom command policies 6621
Configure a command policy by using the NetScaler GUI 6623
Bind command policies to user accounts and user groups 6623
Bind command policies to a user account by using the NetScaler GUI 6624
Bind command policies to a user group by using the NetScaler GUI 6625
Example use case: Manage user accounts, user groups, and command policies in a manufacturing organization 6626
Configure user accounts, groups, and command policies for a sample organization 6627
User account and password management 6629
System user account lockout 6629
Configure system user account lockout by using the GUI 6631

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Lock system user account for management access 6633

Lock a system user account by using the GUI 6633

Unlock a locked system user account for management access 6634

Configure system user unlock by using the GUI 6634

Disable management access for system user account 6635

Disable management access to system user by using the GUI 6635

Force passwords change for administrative users 6636

Remove sensitive files in a system user account 6637

Strong password configuration for system users 6637

Enforce password rotation and password history for local accounts 6638

Configuration and applicability 6638

Important notes for applying changes 6639

Limitation 6639

How to configure and use the password rotation and history feature 6639

Configuration by using the CLI 6639

Configuration by using the GUI 6642

Default user account 6644

How to reset root administrator (`nsroot`) password 6644

External user authentication 6647

LDAP authentication (using external LDAP servers) 6648

Configure LDAP user authentication by using the CLI 6649

Configure LDAP policy 6649

Configure LDAP user authentication by using the NetScaler GUI 6650

Bind an authentication policy to the system global for LDAP authentication using the NetScaler GUI 6651

Determining attributes in the LDAP directory 6652

Key-based authentication support for LDAP users 6653

RADIUS authentication (using external RADIUS servers) 6654

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure RADIUS user authentication by using the CLI 6654

Configure RADIUS user authentication by using the GUI 6655

Bind the authentication policy to the system global for RADIUS authentication by using the GUI 6656

Choose RADIUS user authentication protocols 6657

Configure IP address extraction 6658

Group extraction for RADIUS by using the GUI 6658

TACACS+ authentication (using external TACACS+ servers) 6659

Configure TACACS+ authentication by using the GUI 6659

Bind authentication policies to the system global entity by using the CLI 6660

Bind authentication policies to the system global entity by using the GUI 6660

Display number of unsuccessful logon attempts for external users 6662

SSH key-based authentication for local system users 6664

SSH key-based authentication for local system users 6665

Configure SSH key-based authentication for the NetScaler local system users by using GUI 6665

User-specific SSH key-based authentication for local system users 6666

Configure user-specific SSH key-based authentication by using the CLI 6666

Two factor authentication for system users and external users 6667

How two factor authentication works 6668

Use case 1: Two factor authentication (2FA) across NetScaler, GUI, CLI, API and SSH interfaces 6669

Use case 2: Two factor authentication supported on external authentication servers such as LDAP, RADIUS, Active Directory and TACACS 6669

Use case 3: External authentication enabled and local authentication disabled for system users 6669

Add authentication action for LDAP server (first level authentication) 6670

Add authentication policy for LDAP server (first level authentication) 6670

Add authentication action for RADIUS server (second level authentication) 6670

Add authentication policy for RADIUS server (second level authentication) 6671

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add authentication login schema 6671

Add and bind authentication policy label to RADIUS server 6671

Bind authentication system global for LDAP policy 6671

Disable local authentication in system parameter 6672

Use case 4: External authentication enabled for system user with local authentication policy attached 6672

Add authentication action for LDAP server (first level authentication) 6673

Add authentication policy for LDAP server (first level authentication) 6673

Add local authentication policy for system users (second level authentication) 6673

Add and bind authentication policy label 6673

Disable local authentication in system parameter 6674

Use case 5: External authentication disabled and local authentication enabled for system user 6674

To enable system user password and disable external authentication 6674

Use case 6: External authentication enabled and local authentication enabled for system users 6675

Add authentication action for LDAP server 6675

Add authentication policy for LDAP policy 6676

Add authentication action for RADIUS server 6676

Add advanced authentication policy for RADIUS server 6676

Add authentication login schema 6677

Add and bind authentication policy label to RADIUS authentication policy for user login 6677

Bind authentication policy global 6677

Use case 7: External authentication enabled for selected external users only 6678

Add authentication action for LDAP server 6678

Add authentication policy for LDAP policy 6678

Add authentication action for RADIUS server 6679

Add advanced authentication policy for RADIUS server 6679

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add authentication login schema 6679
Add and bind authentication policy label to RADIUS authentication policy for user login 6679
Bind authentication policy global 6680
Add authentication action for LDAP server 6680
Add authentication policy for LDAP server 6681
Bind authentication system global for LDAP policy 6681
Display customized prompt message for two factor authentication 6681
Configuring two-factor authentication by using the NetScaler GUI 6682
Smart card-based authentication for management GUI access 6684
Configure smart card-based authentication by using the CLI 6685
Configure smart card-based authentication by using the GUI 6688
Access NetScaler® management GUI by using smart card-based authentication 6690
Troubleshoot issues related to smart card-based authentication 6691
References 6691
Restricted system user authentication to NetScaler management interfaces 6691
Configure user access to NetScaler management interfaces by using the CLI 6692
TCP Configurations 6693
Supported TCP configuration 6693
Defending TCP against spoofing attacks as per RFC 5961 6693
Explicit Congestion Notification (ECN) 6693
Round trip time measurement (RTTM) using the timestamp option 6694
Detection of spurious retransmissions 6694
Congestion control 6694
Window scaling 6695
TCP maximum congestion window 6696
Selective acknowledgment (SACK) 6696
Forward acknowledgment (FACK) 6696
TCP connection multiplexing 6696

Dynamic receive buffering 6696
MPTCP Connection 6696
Support for additional address advertisement (ADD_ADDR) in MPTCP 6697
Points to remember about MPTCP ADD_ADDR functionality 6698
Configure more address advertisement (ADD_ADDR) feature to advertise additional VIP address by using the CLI 6698
Add an IP set 6698
Add an IP address of type virtual server IP (VIP) with MPTCP advertise enabled 6699
Bind IP addresses to the IP set 6699
Configure IP set to load balancing virtual server 6699
Configure advertising external IP address using ADD_ADDR functionality 6700
Add an external IP address of type virtual server IP (VIP) with MPTCP advertise enabled 6700
Bind IP addresses to the IP set 6700
Configure IP set to load balancing virtual server 6701
Advertise an IP address to MPTCP enabled clients by using the NetScaler GUI 6701
Extracting the TCP/IP path overlay option and inserting the client-IP HTTP header 6701
TCP segmentation offload 6702
Synchronizing cookie for TCP handshake with clients 6702
Learning MSS to enable MSS learning for all the virtual servers configured on the appliance 6702
Supported TCP Parameters 6702
Setting Global TCP Parameters 6716
Default TCP profile 6717
Global TCP command 6718
TCP buffering feature 6718
Configure the TCP buffering feature globally 6718
Setting Service or Virtual Server Specific TCP Parameters 6719
Built-in TCP Profiles 6720
Sample TCP Configurations 6721

Defending TCP against spoofing attacks 6722
Prior to RFC 5961 compliance support 6722
From NetScaler release 14.1-4.x onwards with RFC 5961 compliance support 6722
Explicit Congestion Notification (ECN) 6723
Selective Acknowledgment (SACK) 6723
Forward Acknowledgment (FACK) 6724
Window Scaling (WS) 6724
Maximum Segment Size (MSS) 6724
NetScaler to learn the MSS of a virtual server 6724
TCP keep-alive 6725
Buffer size - using TCP profile 6725
Buffer size - using TCP buffering feature 6725
MPTCP 6725
Congestion control 6725
Dynamic receive buffering 6726
Support for TCP Fast Open (TFO) in Multipath TCP (MPTCP) 6726
Support for Variable TFO Cookie Size for MPTCP 6726
SYN-Cookie timeout interval 6727
Enhanced ISN generation 6727
Delink client and server connection 6728
Configure the slow start threshold parameter 6728
HTTP configurations 6729
Setting global HTTP parameters 6729
Default HTTP profile 6730
Global HTTP command 6730
Configure HTTP profile to drop TRACE or TRACK invalid requests 6731
Configure HTTP profile for a service group 6731
Configure the HTTP profile using the NetScaler GUI 6732

Setting service or virtual server specific HTTP parameters 6732

To specify service or virtual server level HTTP configurations by using the command line interface 6733

To specify service or virtual server level HTTP configurations by using the GUI 6733

Built-in HTTP profiles 6734

Sample HTTP configurations 6734

HTTP band statistics 6734

WebSocket connections 6734

Configure the NetScaler appliance to delete or pass the upgrade header to the back-end server 6735

Set the passProtocolUpgrade parameter by using the CLI 6735

Set the passProtocolUpgrade parameter by using the GUI 6735

Configure HTTP profile to validate host headers 6736

Validate HTTP host headers using the NetScaler CLI 6736

Validate HTTP host headers using the NetScaler GUI 6736

Configure HTTP profile to validate duplicate HTTP headers 6736

Validate duplicate HTTP headers using the NetScaler CLI 6737

Validate duplicate HTTP headers using the NetScaler GUI 6737

HTTP/2 configuration 6737

How HTTP/2 works 6739

HTTP/2 for HTTPS (SSL) load balancing configuration 6740

HTTP/2 for HTTP load balancing configuration 6740

Before you Begin 6741

Configuring HTTP/2 6741

Sample configurations 6743

Configure HTTP/2 initial connection window size 6744

Configure the HTTP/2 initial connection window size parameter by using the CLI 6745

WebSocket over HTTP/2 configuration 6745

Configure the WebSocket connections over HTTP/2 by using the CLI 6745

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure the WebSocket connections over HTTP/2 by using the GUI 6746

Enable the Extended CONNECT mechanism in HTTP/2 for WebSocket support 6747

Enable or disable the Extended CONNECT mechanism in HTTP/2 by using the CLI 6747

Enable an extended CONNECT mechanism in HTTP/2 by using the GUI 6748

HTTP/2 DoS mitigation 6750

Configure the maximum limit for HTTP/2 frames to mitigate DoS attacks by using the command-line interface 6750

Configure the maximum limit for frames received in an HTTP/2 connection by using the NetScaler GUI 6751

HTTP3 over QUIC protocol 6752

Advantage of using HTTP/3 protocol 6753

Transport stack in HTTP protocols 6753

How QUIC and HTTP/3 connection management works in NetScaler 6753

How HTTP/3 protocol works 6754

HTTP/3 configuration and Stat summary 6755

Enable SSL and load balancing 6756

Add load balancing and content switching (optional) virtual servers of type HTTP_QUIC for HTTP/3 service 6756

Associate QUIC profile with HTTP_QUIC virtual server 6756

Enable and bind HTTP/3 on a HTTP_QUIC virtual server 6759

Bind SSL certificate-key pair with HTTP_QUIC virtual server 6759

Bind SSL/TLS profile with a HTTP_QUIC virtual server 6760

Add services or service groups of type HTTP_QUIC 6761

Associate QUIC profile with HTTP_QUIC services or service groups 6761

Associate the SSL/TLS profile with HTTP_QUIC services or service groups 6762

Add a custom monitor of type QUIC 6763

Associate a QUIC monitor to the HTTP_QUIC services or service groups 6763

Enable SSL and load balancing features by using the GUI 6763

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add load balancing and content switching (optional) virtual servers of type HTTP_QUIC by using the GUI 6764

Associate QUIC profile with the HTTP_QUIC virtual server by using the GUI 6765

Associate SSL/TLS profile with the virtual server of type SSL by using the GUI 6768

Add services or service groups of the type HTTP_QUIC by using the GUI 6770

Associate QUIC profile with the HTTP_QUIC services or service groups by using the GUI 6770

Associate the SSL/TLS profile with the HTTP_QUIC services or service groups by using the GUI 6771

Associate a QUIC monitor to the HTTP_QUIC services or service groups by using the GUI 6771

View QUIC and HTTP/3 statistics 6772

Policy configuration for HTTP/3 traffic 6772

Responder policy configuration for HTTP/3 traffic 6773

Add responder action for redirecting URLs 6773

Add responder policy 6774

Add responder policy based UDP expression 6774

Bind responder policy based UDP expression with HTTP/3 QUIC based load balancing virtual server 6774

Bind responder policy with HTTP/3 QUIC based load balancing virtual server 6775

Bind responder policy to HTTP/3 global bind point 6775

Rewrite policy configuration for HTTP/3 traffic 6775

Add rewrite action for HTTP over QUIC 6776

Add rewrite policy for HTTP over QUIC 6776

Bind rewrite policy to load balancing virtual server of type HTTP/3_QUIC 6776

Bind rewrite policy to HTTP/3 global bind point 6777

Compression policy configuration for HTTP/3 traffic 6777

Add compression policy 6777

Bind compression policy with load balancing virtual server of type HTTP/3_QUIC 6778

Bind compression global to HTTP/3 global bind point 6778

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Caching policy configuration for HTTP/3 traffic 6780
Add cache content group 6781
Add cache policy 6781
Bind cache policy with load balancing virtual server of type HTTP/3_QUIC 6781
Bind cache policy global to HTTP/3 global bind point 6782
Global built-in cache policies 6782
URL Transformation policy configuration for HTTP/3 traffic 6785
Add URL Transform profile 6785
Add URL Transform action 6785
Add URL Transform action 6786
Add URL Transform policy 6786
Bind URL Transform policy with load balancing virtual server of type HTTP/3_QUIC 6786
Bind URL transform policy global with HTTP/3 QUIC based load balancing virtual server 6787
Front end optimization (FEO) policy configuration for HTTP/3 traffic 6787
Add Front end optimization (FEO) action 6787
Add Front end optimization (FEO) policy 6788
Bind FEO policy with load balancing virtual server of type HTTP/3_QUIC 6788
Bind FEO policy to HTTP/3 global bind point 6788
SSL Policy configuration for HTTP/3 traffic 6789
Add SSL Policy 6789
Bind SSL Policy to HTTP/3 virtual server 6789
Add SSL policy with UDP expression for SSL Policy 6789
Bind SSL Policy with UDP expression to HTTP/3 virtual server 6790
Add SSL policy for CLIENTHELLO bind point for HTTP/3 traffic 6790
Bind SSL policy to CLIENTHELLO bind point 6790
Bind SSL policy to HTTP/3 global bind point 6790
Application Firewall Policy configuration for HTTP/3 traffic 6791
Add Web Application Firewall policy with UDP expression 6791

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bind log expressions with UDP based expression for Web Application Firewall profile 6791
Bind Application Firewall policy with HTTP/3 virtual server 6792
Bind Web Application Firewall policy to HTTP/3 global bind point 6792
AppQoE Policy configuration for HTTP/3 traffic 6792
Add AppQoE policy with UDP based expression 6792
Bind AppQoE policy with HTTP/3 virtual server 6793
Bind AppQoE policy to HTTP_QUIC virtual server 6793
HTTP/3 service discovery 6793
Configure HTTP/3 service discovery 6794
Configure HTTP/3 alternative service endpoint by using an HTTP/2 Alt-Svc frame 6795
Configure HTTP/3 alternative service with HTTP Alt-Svc header value by using GUI 6795
gRPC 6796
Why gRPC in NetScaler 6796
gRPC end-to-end configuration 6797
How end-to-end gRPC configuration works 6797
Example for gRPC request sent to gRPC server 6798
Example for gRPC response header from gRPC server to NetScaler appliance 6799
Configure gRPC by using the CLI 6799
Add HTTP profile with HTTP/2 and HTTP/2 direct enabled 6800
Enable global back-end HTTP/2 support through HTTP parameter 6800
Add load balancing virtual server of type SSL/HTTP and set HTTP profile 6800
Add Service for gRPC endpoint and set HTTP profile 6801
Bind gRPC end point service to load balancing virtual server 6801
Configure end-to-end gRPC deployment by using the GUI 6801
Add HTTP profile with HTTP/2 and HTTP/2 direct enabled 6801
Enable global back end HTTP/2 support in HTTP parameter 6801
Add load balancing virtual server of type SSL/HTTP and set HTTP profile 6802
Add Service for gRPC endpoint and set HTTP profile 6802

© 1997–2026 Citrix Systems, Inc. All rights reserved.

gRPC bridging 6802
How gRPC bridging works 6802
Configure gRPC bridging by using the CLI 6803
Add HTTP profile with the HTTP/2 and HTTP/2 direct enabled 6804
Enable global back end HTTP/2 support in the HTTP parameter 6804
Add load balancing virtual server of type SSL/HTTP and set the HTTP profile 6804
Add Service for gRPC endpoint and set the HTTP profile 6805
Bind gRPC end point service to load balancing virtual server 6805
Map gRPC status code to HTTP status-code in the HTTP/1.1 response 6805
Configure gRPC buffering by time and/or size 6806
Configure gRPC bridging by using the GUI 6807
Add HTTP profile with HTTP/2 and HTTP/2 direct enabled 6807
Enable global back-end HTTP/2 support in the HTTP parameter 6808
Add load balancing virtual server of type SSL/HTTP and set HTTP profile 6808
Add Service for gRPC endpoint and set HTTP profile 6808
Bind Service for gRPC endpoint to load balancing virtual server 6808
Configure gRPC buffering by time and size by using the GUI 6808
gRPC reverse bridging 6809
How reverse bridging works 6809
Configure gRPC reverse bridging by using the CLI 6810
Add HTTP profile 1 with HTTP/2 and HTTP/2 direct enabled for load balancing virtual server 6810
Add HTTP profile 2 with HTTP/2 disabled for back-end server 6810
Add load balancing virtual server of type SSL/HTTP and set to HTTP profile 1 6811
Add service for gRPC endpoint and set to HTTP profile 2 6811
Bind service for gRPC endpoint to load balancing virtual server 6811
Map HTTP response code to gRPC status code 6812
Configure gRPC reverse bridging by using the GUI 6812
Add HTTP profile 1 with HTTP/2 and HTTP/2 direct enabled for load balancing virtual server 6812

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add HTTP profile 2 with HTTP/2 disabled for back-end server 6812
Add load balancing virtual server of type SSL/HTTP and set to HTTP profile 1 6813
Add service with gRPC endpoint and set to HTTP profile 2 6813
Bind Service for gRPC endpoint to load balancing virtual server 6813
gRPC call termination 6813
gRPC with rewrite policy 6813
Configure gRPC call termination with rewrite policy 6814
Enable rewrite feature 6814
Add rewrite policy 6815
Bind rewrite policy to load balancing virtual server 6815
gRPC with the responder policy 6815
Configure gRPC call termination with the responder policy by using the CLI 6816
Enable the responder feature 6816
Add the responder action 6817
Adding responder policy 6817
Bind responder policy to load balancing virtual server 6817
Policy expressions for matching gRPC protocol buffer fields 6818
Configure gRPC advance policy expressions by using the CLI 6818
Configure gRPC header filtering parameters by using the GUI 6818
API path matching 6819
gRPC health check monitor 6820
Configure the gRPC health monitor in HTTP/2 by using the command interface 6820
Configure the gRPC health monitor in HTTP/2 by using the GUI 6821
QUIC 6821
Benefits of QUIC bridge 6822
Crypto offload support for QUIC 6822
QUIC bridge configuration 6822
Configure QUIC bridge by using the CLI 6823

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add a QUIC bridge profile 6823
Add QUIC back-end application server 6823
Add QUIC bridge service 6824
Add a load balancing virtual server of type QUIC bridge 6824
Bind QUIC bridge service to the load balancing virtual server of type QUIC bridge 6825
Configure QUIC bridge for service groups 6825
Add QUIC bridge profile 6826
Add server of type QUIC 6826
Add QUIC bridge service group 6826
Bind the QUIC servers to the service group 6826
Add load balancing virtual server of type QUIC bridge 6827
Bind the load balancing virtual server of type QUIC bridge to the service group 6827
Configure QUIC bridge using the GUI 6828
Configure load balancing for the services by using the GUI 6828
View statistics for QUIC bridge 6829
View QUIC bridge statistics by using the GUI 6829
Proxy protocol 6829
Limitations 6830
How proxy protocol works in a NetScaler appliance 6830
Insert operation 6831
Forward operation 6831
Stripped operation 6832
Proxy protocol version formats 6832
Responder policy infrastructure expression support 6833
Configure Proxy protocol in NetScaler appliance 6834
Enable the proxy protocol as global 6834
Configure proxy protocol for Insert operation 6834
Add net profile with Proxy protocol disabled for load balancing virtual server 6834

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add net profile with a proxy protocol enabled for service 6835
Add load balancing virtual server for NetScaler appliance in the proxy layer 6835
Add HTTP service for NetScaler appliance in the proxy layer 6835
Set net profile with load balancing virtual server in NetScaler appliance 6836
Set net profile with HTTP service in NetScaler appliance 6836
Bind the load balancing virtual server to service 6836
Configure proxy protocol for forward operation 6836
Add net profile with proxy protocol enabled for load balancing virtual server 6837
Add net profile with proxy protocol enabled for service 6837
Add load balancing virtual server for NetScaler appliance in the proxy layer 6837
Add HTTP service for NetScaler appliance in the proxy layer 6837
Set net profile with load balancing virtual server in NetScaler appliance 6838
Set net profile with HTTP service in NetScaler appliance 6838
Bind the load balancing virtual server to service 6838
Configure proxy protocol for strip operation 6838
Add net profile with proxy protocol enabled for virtual server 6838
Add load balancing or content switching virtual server for NetScaler appliance in the proxy layer 6839
Add HTTP service for NetScaler appliance in the proxy layer 6839
Set net profile with load balancing or content switching virtual server in NetScaler appliance 6839
Bind the load balancing virtual server to service 6839
Configure responder policy infrastructure expression for proxy protocol by using the CLI 6840
Sample end-to-end configuration 6840
Configure Proxy protocol by using NetScaler GUI 6842
Client IP address in TCP option 6843
Limitations 6844
How TCP option configuration in a NetScaler appliance 6844
Configure TCP option for Insert operation 6845
Sample configuration 6846

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure the TCP option for Forward operation 6846
Sample configuration 6847
Configure TCP option by using NetScaler GUI 6847
SNMP 6848
Importing MIB Files to the SNMP Manager and Trap Listener 6849
Configuring the NetScaler to generate SNMP traps 6849
Enabling an SNMP alarm 6850
To enable an SNMP alarm by using the CLI 6850
To enable an SNMP alarm by using the GUI 6850
Configuring alarms 6850
To configure an SNMP alarm by using the CLI 6851
To configure SNMP alarms by using the GUI 6851
Configuring SNMPv1 or SNMPv2 traps 6852
To add an SNMP trap by using the CLI 6852
To configure SNMP traps by using the GUI 6852
Configuring SNMPv3 traps 6853
To configure an SNMPv3 trap by using the CLI 6853
To configure an SNMPv3 trap by using the GUI 6854
SNMP trap logging 6854
To enable SNMP trap logging and configure trap log level by using the CLI 6854
To enable SNMP trap logging and configure SNMP trap log level by using the GUI 6855
Custom SNMP traps 6855
Configurable custom SNMP traps 6855
User input file 6855
Admin partitions 6859
Custom traps behavior in a high availability setup 6859
Custom traps behavior in a cluster setup 6859
Custom SNMP OIDs 6860

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create a YAML file `custom_get.yaml` 6860
Configure NetScaler for custom SNMP OIDs 6862
Configuring NetScaler for SNMP v1 and v2 queries 6862
Specifying an SNMP manager 6863
To add SNMP managers by specifying IP addresses by using the command line interface 6863
Example 6864
To add an SNMP manager by specifying its host name by using the command line interface 6864
Example 6864
To add an SNMP manager by using the GUI 6864
Specifying an SNMP community 6865
To specify an SNMP community by using the command line interface 6865
Example 6865
To configure an SNMP community string by using the GUI 6865
Configuring NetScaler for SNMPv3 queries 6865
Setting the engine ID 6867
Set the engine ID by using the CLI 6867
Example 6867
Set the engine ID by using the GUI 6867
Configure a view 6867
Add an SNMP view by using the CLI 6867
Examples 6868
Configure an SNMP view by using the GUI 6868
Configure a group 6868
Add an SNMP group by using the CLI 6868
Configure an SNMP group by using the GUI 6869
Configure a user 6869
Configure a user by using the CLI 6869
Example 6870

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure an SNMP user by using the GUI 6870

Configuring SNMP Alarms for rate limiting 6871

Configuring an SNMP alarm for throughput or PPS 6871

To configure an SNMP alarm for the throughput rate by using the CLI 6871

Example 6872

To configure an SNMP alarm for PPS by using the CLI 6872

Example 6872

To configure an SNMP alarm for throughput or PPS by using the GUI 6872

Configuring SNMP alarm for dropped packets 6872

To configure an SNMP alarm for packets dropped because of excessive throughput by using the CLI 6872

To configure an SNMP alarm for packets dropped because of excessive PPS by using the CLI 6873

NetScaler release notes

Release notes describe how the software has changed in a particular build, and the issues known to exist in the build.

NetScaler also supports the following NetScaler cloud native (microservices application delivery) components:

NETSCALER CLOUD NATIVE (MICROSERVICES APPLICATION DELIVERY) COMPONENTS	RELEASE NOTES
NetScaler Ingress Controller	Release notes
NetScaler Kubernetes Gateway Controller	Release notes

NOTE

- The labels under the issue descriptions are internal tracking IDs used by the NetScaler team.
- These release notes do not document security related fixes. For a list of security related fixes and advisories, see the security bulletin.

To view the release notes document for a specific build of release 14.1, click the corresponding link in the following table. When the release notes are updated for a build, the published date is also updated. The published date of the release notes might differ from the GA date of the build. To view the release notes document for a specific FIPS build of release 14.1, see NetScaler 14.1 FIPS release notes.

Getting started with NetScaler

This topic describes the basic features and configuration details of a NetScaler appliance. System and network administrators who install and configure network equipment can refer to the content.

Understanding NetScaler

The NetScaler appliance is an application switch that performs application-specific traffic analysis to intelligently distribute, optimize, and secure Layer 4-Layer 7 (L4–L7) network traffic for web applications. For example, a NetScaler appliance load balances decisions on individual HTTP requests instead of long-lived TCP connections. The load balancing feature helps slow down the failure of a server with less disruption to clients. The ADC features can be broadly classified as:

1. Data switching
2. Firewall security
3. Optimization
4. Policy infrastructure
5. Packet flow

Data switching

When deployed in front of application servers, a NetScaler ensures optimal distribution of traffic by how it directs client requests. Administrators can segment application traffic according to information in the body of an HTTP or TCP request, and based on L4–L7 header information such as URL, application data type, or cookie. Numerous load balancing algorithms and extensive server health checks improve application availability by ensuring that client requests are directed to the appropriate servers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Firewall security

The NetScaler security and protection protect web applications from Application Layer attacks. An ADC appliance allows legitimate client requests and can block malicious requests. It provides built-in defenses against denial-of-service (DoS) attacks and supports features that protect against legitimate surges in application traffic that overwhelms the servers. An available built-in firewall protects web applications from Application Layer attacks, including buffer overflow exploits, SQL injection attempts, cross-site scripting attacks, and more. In addition, the firewall provides identity theft protection by securing confidential corporate information and sensitive customer data.

Optimization

Optimization offloads resource-intensive operations, such as Secure Sockets Layer (SSL) processing, data compression, client keep-alive, TCP buffering, and the caching of static and dynamic content from servers. This improves the performance of the servers in the server farm and therefore speeds up applications. An ADC appliance supports several transparent TCP optimizations, which mitigate problems caused by high latency and congested network links. This accelerates the delivery of applications while requiring no configuration changes to clients or servers.

Policy infrastructure

A policy defines specific details of traffic filtering and management on a NetScaler. It consists of two parts: the expression and the action. The expression defines the types of requests that the policy matches. The action tells the ADC appliance what to do when a request matches the expression. For example, the expression might be to match a specific URL pattern for a security attack with the configured to drop or reset the connection. Each policy has a priority, and the priorities determine the order in which the policies are evaluated.

When an ADC appliance receives traffic, the appropriate policy list determines how to process the traffic. Each policy on the list contains one or more expressions, which together define the criteria that a connection must meet to match the policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For all policy types except rewrite, the appliance implements only the first policy that has a request match. For Rewrite policies, the ADC appliance evaluates the policies in order and performs the associated actions in the same order. Policy priority is important for getting the results you want.

Packet flow

Depending on requirements, you can choose to configure multiple features. For example, you might choose to configure both compression and SSL offload. As a result, an outgoing packet might be compressed and then encrypted before being sent to the client.

The following figure shows the HTTP2 packet flow in the NetScaler appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

If the traffic is for a content switching virtual server, the appliance evaluates policies in the following order:

1. bound to global override.
2. bound to load balancing virtual server.
3. bound to content switching virtual server.
4. bound to global default.

This way, if a policy rule is true and `gotoprioritynexpression` is END, we stop further policy evaluation. In content switching, if no load balancing virtual server is selected or bound to the content switching virtual server, then we evaluate responder policies bound only to the content switching virtual server.

Where does a NetScaler appliance fit in the network?

NetScaler® resides between the clients and servers in the network. It plays the role of an intermediary, processing the traffic flowing between the client and server. For the traffic coming from the clients, NetScaler acts as a server and receives the requests. After receiving the client request, NetScaler sends a new request on behalf of the client to the server. In sending the request to the server, NetScaler acts as a client.

The following are a few common network deployments where the NetScaler fits:

- **Gateway** - You can use NetScaler as a gateway at the perimeter of your organization's internal network (or intranet) to provide a secure single point of access to the servers, applications, and other network resources that reside in the internal network.
- **Application firewall** - You can use NetScaler as an application firewall to prevent security breaches, data loss, and possible unauthorized modifications to websites that access sensitive business or customer information. It does so by filtering both requests and responses, examining them for evidence of malicious activity, and blocking requests that exhibit such activity.
- **Load balancer** - You can use the NetScaler to operate as a load balancer where it distributes client requests across multiple servers to optimize resource utilization. In a real-world scenario with a limited number of servers providing service to many clients, a server can become overloaded and degrade the performance of the server farm. A NetScaler appliance uses load

© 1997–2026 Citrix Systems, Inc. All rights reserved.

balancing criteria to prevent bottlenecks by forwarding each client request to the server best suited to handle the request when it arrives.

- **Global server load balancer** - You can configure NetScaler as a global server load balancer (GSLB) to provide disaster recovery and ensure continuous availability of applications against points of failure in a WAN. GSLB balances the load across data centers by directing client requests to the closest or best performing data center, or to surviving data centers if there is an outage.
- **Packet forwarder** - You can use NetScaler as a packet forwarder to forward packets to an IP not owned by it. NetScaler behaves like a router, looking at the routes it has learned or that has been configured to forward packets.

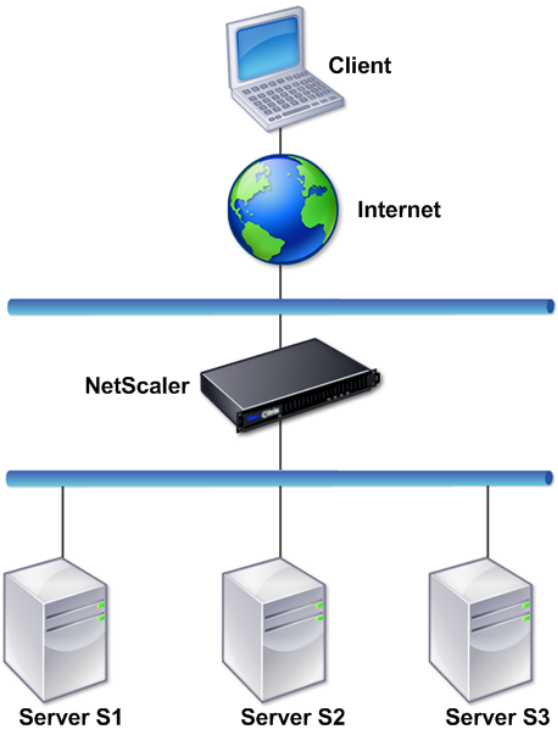
Physical deployment modes

A NetScaler appliance logically residing between clients and servers can be deployed in either of two physical modes:

- Inline or Two-arm mode
- One-arm mode

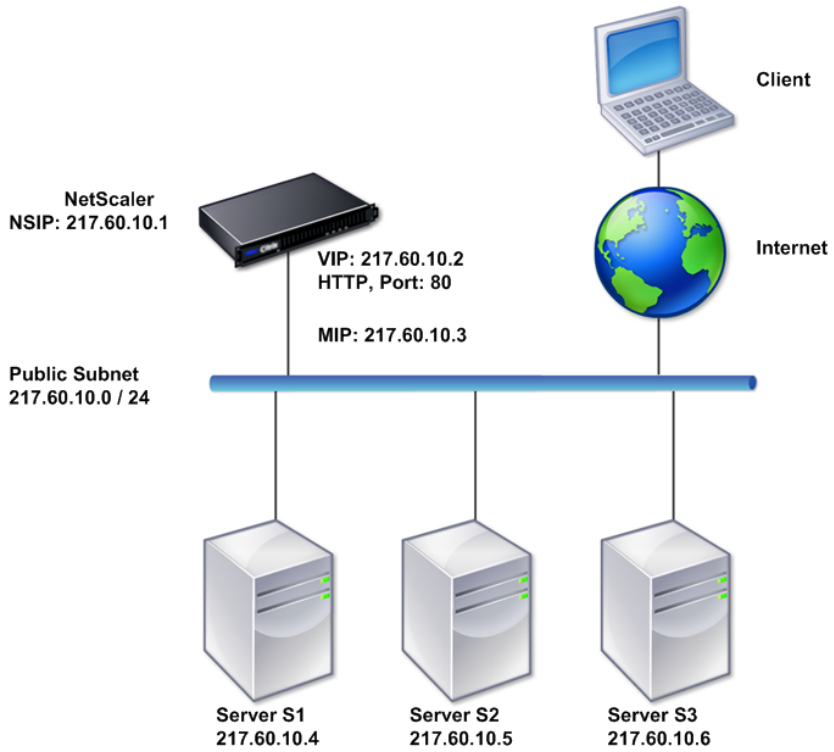
In inline mode, the appliance uses multiple network interfaces to connect to different Ethernet segments, positioning itself between clients and servers. It can connect to the server network with one or more redundant interfaces, and both the appliance and servers can be on separate subnets. It is possible for the servers to be in a public network and the clients to directly access the servers through the appliance, with the appliance transparently applying the L4-L7 features. Usually, virtual servers (described later) are configured to provide an abstraction of the real servers. The following figure shows a typical inline deployment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



In one-arm mode, only one network interface of the appliance is connected to an Ethernet segment. The appliance in this case does not isolate the client and server sides of the network, but provides access to applications through configured virtual servers. One-arm mode can simplify network changes needed for NetScaler installation in some environments.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



For examples of inline (two-arm) and one-arm deployment, see Understanding Common Network Topologies.

How a NetScaler appliance communicates with clients and servers

A NetScaler appliance is usually deployed in front of a server farm and functions as a transparent TCP proxy between clients and servers, without requiring any client-side configuration. This basic mode of operation is called Request Switching technology and is the core of NetScaler functionality. Request Switching enables an appliance to multiplex and offload the TCP connections, maintain persistent connections, and manage traffic at the request (application layer) level. This is possible because the appliance can separate the HTTP request from the TCP connection on which the request is delivered.

Depending on the configuration, an appliance might process the traffic before forwarding the request to a server. For example, if the client attempts to access a secure application on the server, the appliance might perform the necessary SSL processing before sending traffic to the server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To facilitate efficient and secure access to server resources, an appliance uses a set of IP addresses collectively known as NetScaler-owned IP addresses. To manage your network traffic, you assign NetScaler-owned IP addresses to virtual entities that become the building blocks of your configuration. For example, to configure load balancing, you create virtual servers to receive client requests and distribute them to services, which are entities representing the applications on your servers.

Understanding NetScaler-owned IP addresses

To function as a proxy, a NetScaler appliance uses a variety of IP addresses. The key NetScaler-owned IP addresses are:

- NetScaler IP (NSIP) address

  The NSIP address is the IP address for management and general system access to the appliance itself, and for communication between appliances in a high availability configuration.
- Virtual server IP (VIP) address

  A VIP address is the IP address associated with a virtual server. It is the public IP address to which clients connect. An appliance managing a wide range of traffic may have many VIPs configured.
- Subnet IP (SNIP) address

  A SNIP address is used in connection management and server monitoring. You can specify multiple SNIP addresses for each subnet. SNIP addresses can be bound to a VLAN.
- IP Set

  An IP set is a set of IP addresses, which are configured on the appliance as SNIP . An IP set is identified with a meaningful name that helps in identifying the usage of the IP addresses contained in it.
- Net Profile

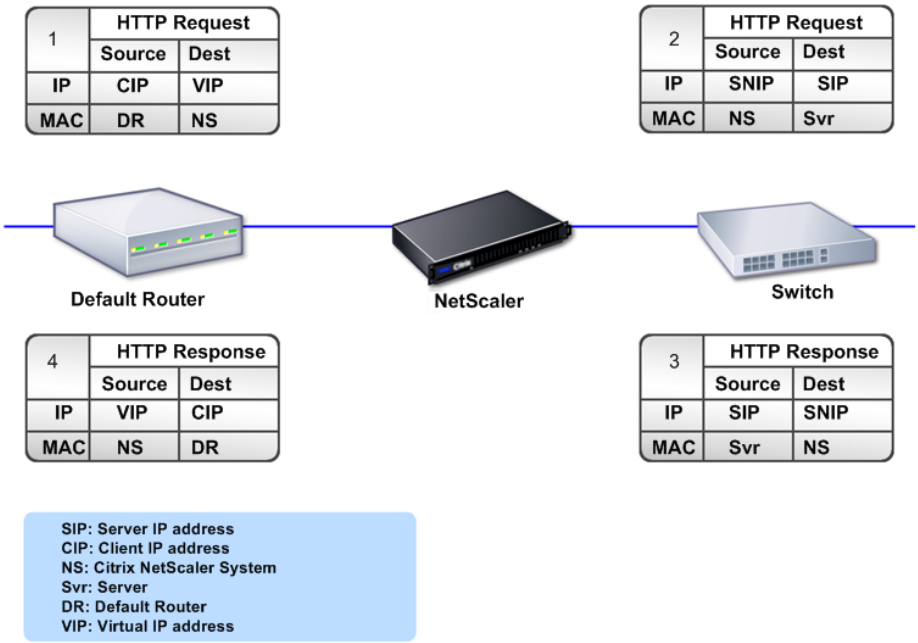
  A net profile (or network profile) contains an IP address or an IP set. A net profile can be bound to load balancing or content switching virtual servers, services, service groups, or monitors. During communication with physical servers or peers, the appliance uses the addresses specified in the profile as source IP addresses.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How Traffic flows are managed

Because a NetScaler appliance functions as a TCP proxy, it translates IP addresses before sending packets to a server. When you configure a virtual server, clients connect to a VIP address on the NetScaler appliance instead of directly connecting to a server. As determined by the settings on the virtual server, the appliance selects an appropriate server and sends the client's request to that server. By default, the appliance uses a SNIP address to establish connections with the server, as shown in the following figure.

Figure 1. Virtual Server Based Connections



In the absence of a virtual server, when an appliance receives a request, it transparently forwards the request to the server. This is called the transparent mode of operation. When operating in transparent mode, an appliance translates the source IP addresses of incoming client requests to the SNIP address but does not change the destination IP address. For this mode to work, L2 or L3 mode has to be configured appropriately.

For cases in which the servers need the actual client IP address, the appliance can be configured to modify the HTTP header by inserting the client IP address as an additional field, or configured to use the client IP address instead of a SNIP address for connections to the servers.

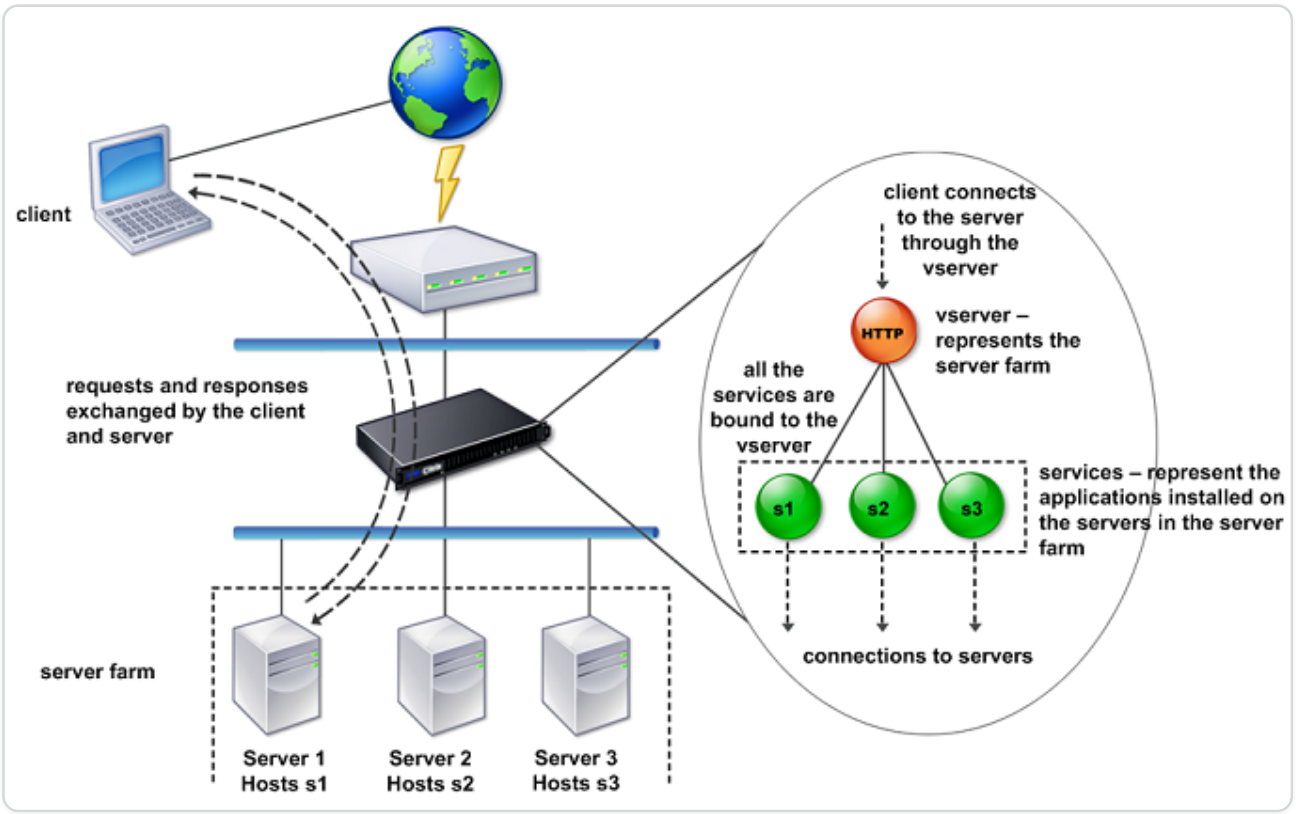
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Traffic management building blocks

The configuration of a NetScaler appliance is typically built up with a series of virtual entities that serve as building blocks for traffic management. The building block approach helps separate traffic flows. Virtual entities are abstractions, typically representing IP addresses, ports, and protocol handlers for processing traffic. Clients access applications and resources through these virtual entities. The most commonly used entities are virtual servers and services. Virtual servers represent groups of servers in a server farm or remote network, and services represent specific applications on each server.

Most features and traffic settings are enabled through virtual entities. For example, you can configure an appliance to compress all server responses to a client that is connected to the server farm through a particular virtual server. To configure the appliance for a particular environment, you need to identify the appropriate features and then choose the right mix of virtual entities to deliver them. Most features are delivered through a cascade of virtual entities that are bound to each other. In this case, the virtual entities are like blocks being assembled into the final structure of a delivered application. You can add, remove, modify, bind, enable, and disable the virtual entities to configure the features. The following figure shows the concepts covered in this section.

Figure 2. How traffic management building blocks work



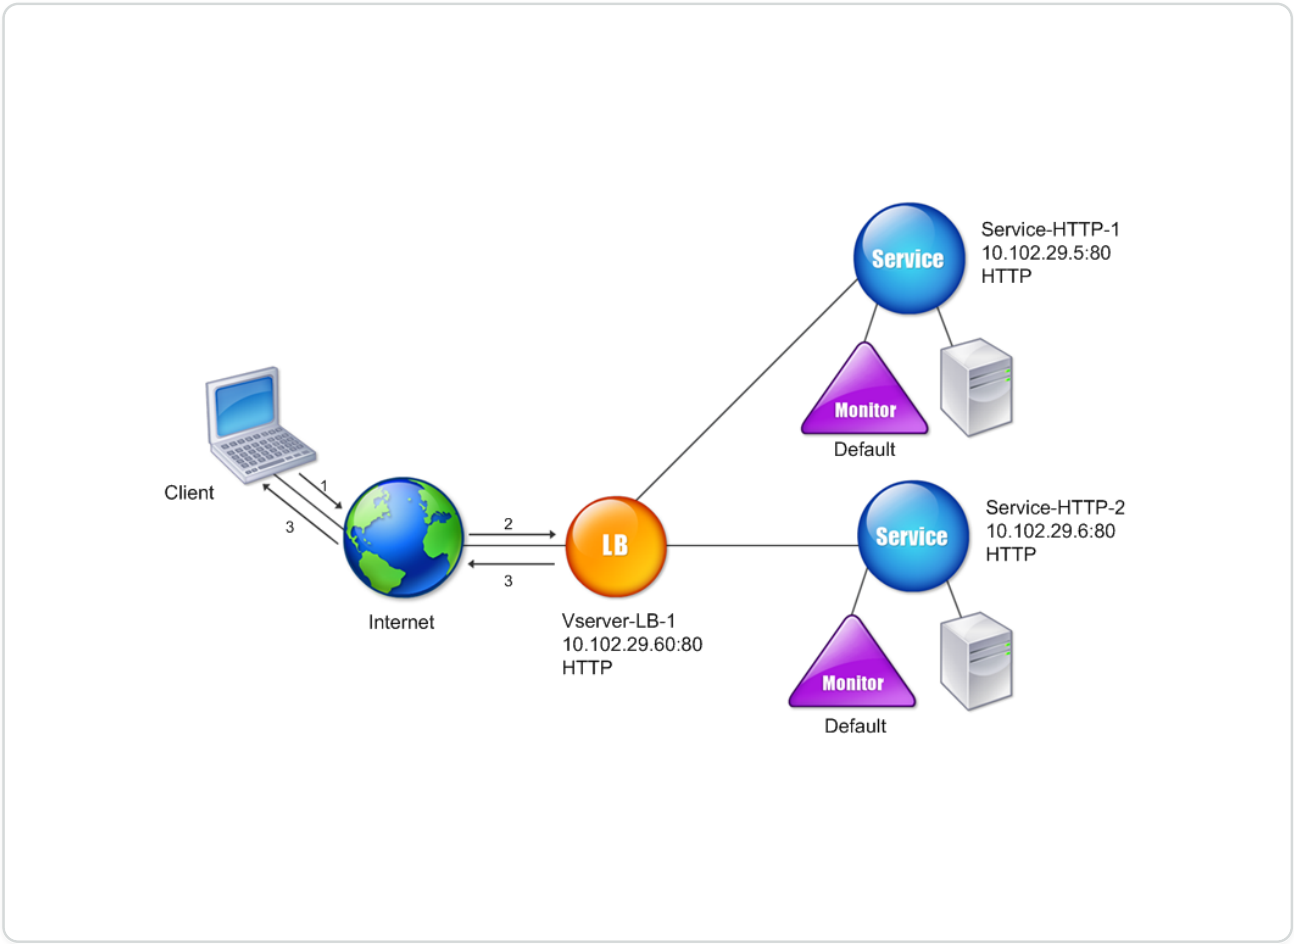
© 1997–2026 Citrix Systems, Inc. All rights reserved.

A simple load balancing configuration

In the example shown in the following figure, the NetScaler appliance is configured to function as a load balancer. For this configuration, you need to configure virtual entities specific to load balancing and bind them in a specific order. As a load balancer, an appliance distributes client requests across several servers and thus optimizes the utilization of resources.

The basic building blocks of a typical load balancing configuration are services and load balancing virtual servers. The services represent the applications on the servers. The virtual servers abstract the servers by providing a single IP address to which the clients connect. To ensure that client requests are sent to a server, you need to bind each service to a virtual server. That is, you must create services for every server and bind the services to a virtual server. Clients use the VIP address to connect to a NetScaler appliance. When the appliance receives client requests sent to the VIP address, it sends them to a server determined by the load balancing algorithm. Load balancing uses a virtual entity called a monitor to track whether a specific configured service (server plus application) is available to receive requests.

Figure 3. Load balancing virtual server, services, and monitors



In addition to configuring the load balancing algorithm, you can configure several parameters that affect the behavior and performance of the load balancing configuration. For example, you can

© 1997–2026 Citrix Systems, Inc. All rights reserved.

configure the virtual server to maintain persistence based on source IP address. The appliance then directs all requests from any specific IP address to the same server.

Understanding virtual servers

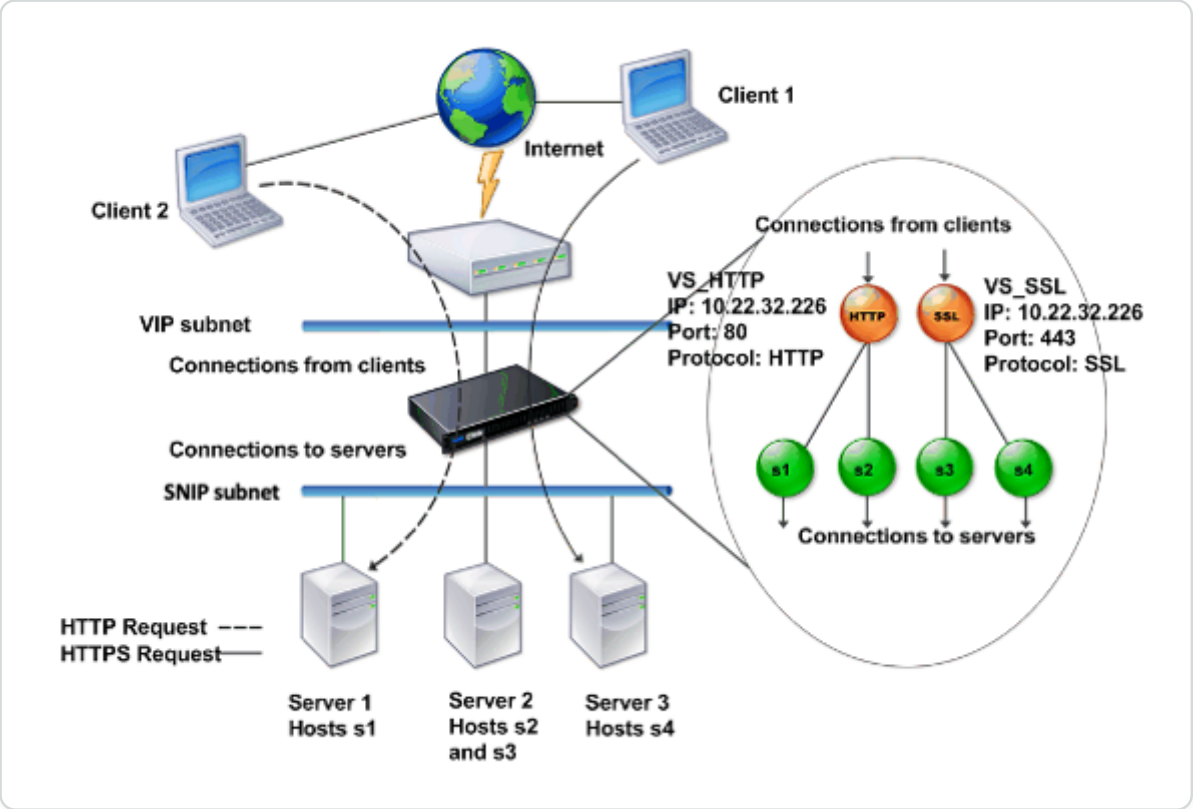
A virtual server is a named NetScaler entity that external clients can use to access applications hosted on the servers. It is represented by an alphanumeric name, virtual IP (VIP) address, port, and protocol. The name of the virtual server is of only local significance and is designed to make the virtual server easier to identify. When a client attempts to access applications on a server, it sends a request to the VIP instead of the IP address of the physical server. When the appliance receives a request at the VIP address, it terminates the connection at the virtual server and uses its own connection with the server on behalf of the client. The port and protocol settings of the virtual server determine the applications that the virtual server represents. For example, a web server can be represented by a virtual server and a service whose port and protocol are set to 80 and HTTP, respectively. Multiple virtual servers can use the same VIP address but different protocols and ports.

Virtual servers are points for delivering features. Most features, like compression, caching, and SSL offload, are normally enabled on a virtual server. When the appliance receives a request at a VIP address, it chooses the appropriate virtual server by the port on which the request was received and its protocol. The appliance then processes the request as appropriate for the features configured on the virtual server.

In most cases, virtual servers work in tandem with services. You can bind multiple services to a virtual server. These services represent the applications running on physical servers in a server farm. After the appliance processes requests received at a VIP address, it forwards them to the servers as determined by the load balancing algorithm configured on the virtual server. The following figure illustrates these concepts.

Figure 4. Multiple Virtual Servers with a Single VIP Address

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The preceding figure shows a configuration consisting of two virtual servers with a common VIP address but different ports and protocols. Each of the virtual servers has two services bound to it. The services s1 and s2 are bound to VS_HTTP and represent the HTTP applications on Server 1 and Server 2. The services s3 and s4 are bound to VS_SSL and represent the SSL applications on Server 2 and Server 3 (Server 2 provides both HTTP and SSL applications). When the appliance receives an HTTP request at the VIP address, it processes the request as specified by the settings of VS_HTTP and sends it to either Server 1 or Server 2. Similarly, when the appliance receives an HTTPS request at the VIP address, it processes it as specified by the settings of VS_SSL and it sends it to either Server 2 or Server 3.

Virtual servers are not always represented by specific IP addresses, port numbers, or protocols. They can be represented by wildcards, in which case they are known as wildcard virtual servers. For example, when you configure a virtual server with a wildcard instead of a VIP, but with a specific port number, the appliance intercepts and processes all traffic conforming to that protocol and destined for the predefined port. For virtual servers with wildcards instead of VIPs and port numbers, the appliance intercepts and processes all traffic conforming to the protocol.

Virtual servers can be grouped into the following categories:

- Load balancing virtual server

  Receives and redirects requests to an appropriate server. Choice of the appropriate server is based on which of the various load balancing methods the user configures.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Cache redirection virtual server

  Redirects client requests for dynamic content to origin servers, and requests for static content to cache servers. Cache redirection virtual servers often work in conjunction with load balancing virtual servers.

- Content switching virtual server

  Directs traffic to a server on the basis of the content that the client has requested. For example, you can create a content switching virtual server that directs all client requests for images to a server that serves images only. Content switching virtual servers often work in conjunction with load balancing virtual servers.

- Virtual private network (VPN) virtual server

  Decrypts tunneled traffic and sends it to intranet applications.

- SSL virtual server

  Receives and decrypts SSL traffic, and then redirects to an appropriate server. Choosing the appropriate server is similar to choosing a load balancing virtual server.

Understanding services

Services represent applications on a server. While services are normally combined with virtual servers, in the absence of a virtual server, a service can still manage application-specific traffic. For example, you can create an HTTP service on a NetScaler appliance to represent a web server application. When the client attempts to access a web site hosted on the web server, the appliance intercepts the HTTP requests and creates a transparent connection with the web server.

In service-only mode, an appliance functions as a proxy. It terminates client connections, uses a SNIP address to establish a connection to the server, and translates the source IP addresses of incoming client requests to a SNIP address. Although the clients send requests directly to the IP address of the server, the server sees them as coming from the SNIP address. The appliance translates the IP addresses, port numbers, and sequence numbers.

A service is also a point for applying features. Consider the example of SSL acceleration. To use this feature, you must create an SSL service and bind an SSL certificate to the service. When the appliance receives an HTTPS request, it decrypts the traffic and sends it, in clear text, to the server. Only a limited set of features can be configured in the service-only case.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Services use entities called monitors to track the health of applications. Every service has a default monitor, which is based on the service type, bound to it. As specified by the settings configured on the monitor, the appliance sends probes to the application at regular intervals to determine its state. If the probes fail, the appliance marks the service as down. In such cases, the appliance responds to client requests with an appropriate error message or re-routes the request as determined by the configured load balancing policies.

For more information about configuring load balancing virtual servers, services, and monitors, see NetScaler Load balancing.

Introduction to the NetScaler product line

The NetScaler product line optimizes delivery of applications over the internet and private networks, combining application-level security, optimization, and traffic management into a single, integrated appliance. You can install a NetScaler appliance in your server room and route all connections to your managed servers through it. The NetScaler features that you enable and the policies you set are then applied to incoming and outgoing traffic.

A NetScaler appliance can be integrated into any network as a complement to existing load balancers, servers, caches, and firewalls. It requires no additional client or server-side software, and can be configured using the NetScaler web-based GUI and CLI configuration utilities.

This topic includes the following sections:

- NetScaler Hardware Platforms
- NetScaler Editions
- Supported Releases on ADC Hardware
- Supported Browsers

NetScaler Hardware Platforms

NetScaler hardware is available in various platforms that have a range of hardware specifications:

NetScaler MPX hardware platform

NetScaler SDX hardware platform

NetScaler Editions

The NetScaler operating system is available in two editions:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Advanced
- Premium

Features are enabled based on the license.

Supported releases on NetScaler hardware

See the following compatibility matrix tables for all NetScaler hardware platforms and the software releases supported on these platforms:

NetScaler MPX Hardware-Software Compatibility Matrix

NetScaler SDX Hardware-Software Compatibility Matrix

Compatible browsers

To access the NetScaler GUI, your workstation must have a compatible web browser.

The following table lists the supported web browsers for accessing the NetScaler GUI in versions 14.1 and 13.1:

WEB BROWSERS	SUPPORTED VERSIONS	COMPATIBLE OPERATING SYSTEMS
Google Chrome	Version 113 and newer	Windows, macOS
Mozilla Firefox	Version 111 and newer	Windows, macOS
Microsoft Edge	Version 112 and newer (Chromium-based)	Windows, macOS
Apple Safari	Version 17 and newer	macOS, iOS
Opera	Version 98 and newer (Chromium-based)	Windows, macOS, Linux

Install the hardware

Before installing a NetScaler appliance, review the pre-installation checklist.

To use the SDX appliance, you must complete the following tasks by following the instructions given in the resources provided in table. Complete the tasks in the sequence given.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Task	Description
1. Read safety, cautions, warnings, and other information	Read the caution and danger information you need to know, before installing the product.
2. Prepare for installation	Unpack your appliance and ensure all parts were delivered, prepare the site and rack, and follow basic electrical safety precautions before you install your new appliance.
3. Install the hardware	Rack mount the appliance, install transceivers (if available), and connect the appliance to the network and a power source.
4. Configure the appliance.	Configure the initial settings of the NetScaler appliance by using the GUI or the serial console. Follow the steps given in the following documentations to complete these tasks: • NetScaler MPX hardware documentation • NetScaler SDX hardware documentation

Access a NetScaler appliance

A NetScaler appliance has both a command line interface (CLI) and a GUI. The GUI includes a configuration utility for configuring the appliance and a statistical utility, called Dashboard. For initial access, all appliances ship with the default NetScaler IP address (NSIP) of 192.168.100.1 and the default subnet mask of 255.255.0.0. You can assign a new NSIP and an associated subnet mask during initial configuration.

If you encounter an IP address conflict when deploying multiple NetScaler units, check for the following possible causes:

- Did you select an NSIP that is an IP address already assigned to another device on your network?
- Did you assign the same NSIP to multiple NetScaler appliances?
- The NSIP is reachable on all physical ports. The ports on a NetScaler are host ports, not switch ports.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following table summarizes the available access methods.

ACCESS METHOD	PORT	DEFAULT IP ADDRESS REQUIRED? (Y/N)
CLI	Console	N
CLI and GUI	Ethernet	Y

Command line interface

Access the CLI locally by connecting a workstation to the console port, or remotely by connecting through the secure shell (SSH) from any workstation on the same network.

Log on to the Command Line Interface through the Console Port

The appliance has a console port for connecting to a computer workstation. To log on to the appliance, you need a serial crossover cable and a workstation with a terminal emulation program.

To log on to the CLI through the console port, follow these steps:

1. Connect the console port to a serial port on the workstation. For more information, see Connect the console cable.
2. On the workstation, start HyperTerminal or any other terminal emulation program. If the logon prompt does not appear, you might have to press ENTER one or more times to display it.
3. In User Name, type `nsroot`. In Password, type `nsroot` and if that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

Log on to the Command Line Interface by using SSH

The SSH protocol is the preferred remote access method for accessing an appliance remotely from any workstation on the same network. You can use either SSH version 1 (SSH1) or SSH version 2 (SSH2.)

If you do not have a working SSH client, you can download and install any of the following SSH client programs:

- PuTTY

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Open Source software supported on multiple platforms. Available at:

`<http://www.chiark.greenend.org.uk/~sgtatham/putty/>`

- `Vandyke` Software SecureCRT

  Commercial software supported on the Windows platform. Available at:

  `<http://www.vandyke.com/products/securecrt/>`

These programs are tested by the NetScaler team, who have verified that they work correctly with a NetScaler appliance. Other programs might also work correctly, but have not been tested.

To verify that the SSH client is installed properly, use it to connect to any device on your network that accepts SSH connections.

To log on to a NetScaler appliance by using an SSH client, follow these steps:

1. On your workstation, start the SSH client.
2. For initial configuration, use the default IP address (NSIP), which is 192.168.100.1. For subsequent access, use the NSIP that was assigned during initial configuration. Select either SSH1 or SSH2 as the protocol.
3. In User Name, type `nsroot`. In Password, type `nsroot` and if that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance. For example.

```
login as: nsroot

Using keyboard-interactive authentication.

Password:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Last login: Tue Jun 16 10:37:28 2009 from 10.102.29.9

Done

```

NetScaler GUI

IMPORTANT:

A certificate-key pair is required for HTTPS access to the Citric ADC GUI. On the ADC, a certificate-key pair is automatically bound to the internal services. On an MPX or SDX appliance, the default key size is 1024 bytes, and on a VPX instance, the default key size is 512 bytes. However, most browsers today do not accept a key that is less than 1024 bytes. As a result, HTTPS access to the VPX configuration utility is blocked.

Also, if a license is not present on an MPX appliance when it starts, and you add a license later and restart the appliance, you might lose the certificate binding.

Citrix® recommends that you install a certificate-key pair of at least 1024 bytes on the appliance for HTTPS access to the GUI. Also, install an appropriate license before starting the appliance.

The GUI includes a configuration utility and a statistical utility, called Dashboard, either of which you access through a workstation connected to an Ethernet port on the appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The system requirements for the workstation running the GUI are as follows:

- For Windows-based workstations, a Pentium 166 MHz or faster processor.
- For Linux-based workstations, a Pentium platform running Linux kernel v2.2.12 or above, and `glibc` version 2.12–11 or later. A minimum of 32 MB RAM is required, and 48 MB RAM is recommended. The workstation must support 16-bit color mode, KDE, and KWM window managers used in conjunction, with displays set to local hosts.
- For Solaris-based workstations, a Sun running either Solaris 2.6, Solaris 7, or Solaris 8.

Your workstation must have a supported web browser to access the configuration utility and Dashboard.

The following table lists the compatible browsers for NetScaler GUI version 12.1, 13.0, and 13.1:

OPERATING SYSTEM	BROWSER	VERSIONS
Windows 10 and later	Edge	110.1587.63 and later
Windows 10 and later	Mozilla Firefox	102 and later
Windows 10 and later	Chrome	108 and later
MAC	Mozilla Firefox	110.0.1 and later
MAC	Safari	15.5 and later

Use the NetScaler GUI

Once you log on to the configuration utility, you can configure the appliance through a graphical interface that includes context-sensitive help.

To log on to the GUI, follow these steps:

1. Open your web browser and enter the NetScaler IP (NSIP) as an HTTP address. If you have not yet set up the initial configuration, enter the default NSIP (http://192.168.100.1). The NetScaler logon page appears.

   Note: If you have two NetScaler appliances in a high availability setup, do not access the GUI by entering the IP address of the secondary NetScaler appliance. If you do so and use the GUI to configure the secondary appliance, your configuration changes are not applied to the primary NetScaler appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. In the User Name text box, type `nsroot`.
3. In the Password text box, type the administrative password you assigned to the `nsroot` account during initial configuration and click **Login**. If that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

   To access the online help, select Help from the Help menu at the top right corner.

Use the Statistical Utility

Dashboard, the statistical utility, is a browser-based application that displays charts and tables on which you can monitor the performance of a NetScaler appliance.

To log on to Dashboard, follow these steps:

1. Open your web browser and enter the NSIP as an HTTP address. The NetScaler® logon page appears.
2. In the User Name text box, type `nsroot`.
3. In the Password text box, type the administrative password you assigned to the `nsroot` account during initial configuration. If that password does not work, try typing the serial number of the appliance. The serial number bar code is available at the back of the appliance.

Configure the ADC for the first time

For initial configuration of a NetScaler MPX appliance, see Initial Configuration of a NetScaler MPX appliance.

For initial configuration of a NetScaler SDX appliance, see Initial Configuration of a NetScaler SDX appliance.

NITRO API

You can use the NITRO API to configure the NetScaler appliance. NITRO exposes its functionality through Representational State Transfer (REST) interfaces. Therefore, NITRO applications can be developed in any programming language. Additionally, for applications that must be developed in Java or .NET or Python, NITRO APIs are exposed through relevant libraries that are packaged as separate Software Development Kits (SDKs). For more information, see NITRO API.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Secure your NetScaler deployment

To maintain security through the deployment life cycle of NetScaler appliance, Citrix recommends you to consider the following security aspects:

- Physical Security
- Appliance Security
- Network Security
- Administration and Management

Different deployments might require different security considerations. The NetScaler secure deployment guidelines provide general security guidance to help you decide on an appropriate secure deployment based on your specific security requirements.

For more information on guidelines for securely deploying the NetScaler appliance, see NetScaler secure deployment guidelines.

Configure high availability

You can deploy two NetScaler appliances in a high availability configuration, where one unit actively accepts connections and manages servers while the secondary unit monitors the first. The NetScaler appliance that is actively accepting connections and managing the servers is called a primary unit and the other one is called a secondary unit in a high availability configuration. If there is a failure in the primary unit, the secondary unit becomes the primary and begins actively accepting connections.

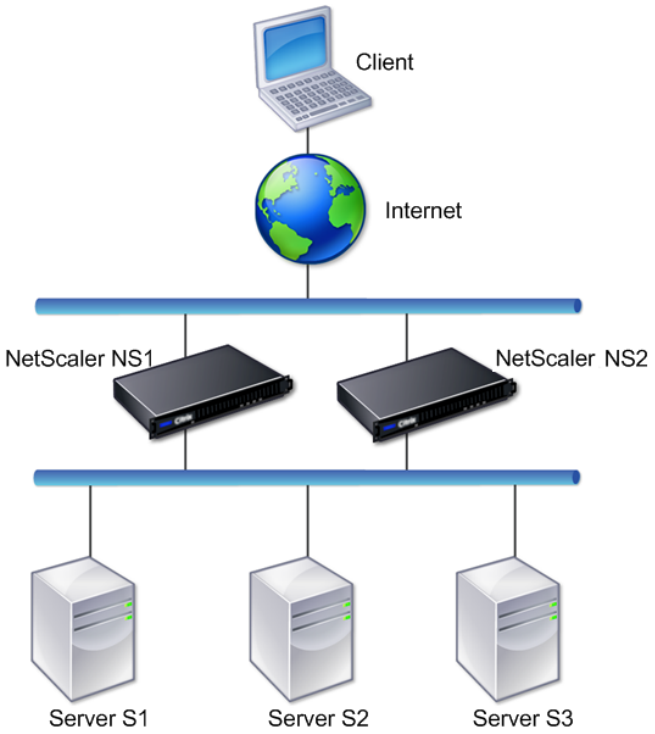
Each NetScaler appliance in a high availability pair monitors the other by sending periodic messages, called heartbeat messages or health checks, to determine the health or state of the peer node. If a health check for a primary unit fails, the secondary unit retries the connection for a specific time period. For more information about high availability, see High Availability. If a retry does not succeed by the end of the specified time period, the secondary unit takes over for the primary unit in a process called failover. The following figure shows two high availability configurations, one in one-arm mode and the other in two-arm mode.

Figure 1. High availability in one-arm mode

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Figure 2. High availability in two-arm mode

© 1997–2026 Citrix Systems, Inc. All rights reserved.



In one-arm configuration, both NS1 and NS2 and servers S1, S2, and S3 are connected to the switch.

In two-arm configuration, both NS1 and NS2 are connected to two switches. The servers S1, S2, and S3 are connected to the second switch. The traffic between client and the servers passes through either NS1 or NS2.

To set up a high availability environment, configure one ADC appliance as primary and another as secondary. Perform the following tasks on each of the ADC appliances:

- Add a node.
- Disable high availability monitoring for unused interfaces.

Add a Node

A node is a logical representation of a peer NetScaler appliance. It identifies the peer unit by ID and NSIP. An appliance uses these parameters to communicate with the peer and track its state. When you add a node, the primary and secondary units exchange heartbeat messages asynchronously. The node ID is an integer that must not be greater than 64.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Through CLI

To add a node by using the command line interface, follow these steps:

At the command prompt, type the following commands to add a node and verify that the node has been added:

- add HA node \<id\> \<IPAddress\>
- show HA node \<id\>

Example

```
add HA node 0 10.102.29.170

 Done

> show HA node 0

1)      Node ID:      0

        IP:   10.102.29.200 (NS200)

        Node State: UP

        Master State: Primary

        SSL Card Status: UP

        Hello Interval: 200 msecs

        Dead Interval: 3 secs

        Node in this Master State for: 1:0:41:50 (days:hrs:min:sec)
```

Through GUI

To add a node by using the GUI, follow these steps:

1. Navigate to **System** > **High Availability**.
2. Click **Add** on the **Nodes** tab.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. On the **Create HA Node** page, in the **Remote Node IP Address** text box, type the NSIP Address (for example, 10.102.29.170) of the remote node.
4. Ensure that the **Configure remote system to participate in High Availability setup** check box is selected. Provide the login credentials of the remote node in the text boxes under **Remote System Login Credentials**.
5. Select the **Turn off HA monitor on interfaces/channels that are down** check box to disable the HA monitor on interfaces that are down.

Verify that the node you added appears in the list of nodes in the Nodes tab.

Disable high availability monitoring for unused interfaces

The high availability monitor is a virtual entity that monitors an interface. You must disable the monitor for interfaces that are not connected or being used for traffic. When the monitor is enabled on an interface whose status is DOWN, the state of the node becomes NOT UP. In a high availability configuration, a primary node entering a NOT UP state might cause a high availability failover. An interface is marked DOWN under the following conditions:

- The interface is not connected
- The interface is not working properly
- The cable connecting the interface is not working properly

Through CLI

To disable the high availability monitor for an unused interface by using the command line interface, follow these steps:

At the command prompt, type the following commands to disable the high availability monitor for an unused interface and verify that it is disabled:

- set interface \<id\> -haMonitor OFF
- show interface \<id\>

Example

```
> set interface 1/8 -haMonitor OFF

 Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> show interface 1/8

        Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2

        flags=0x4000 <ENABLED, DOWN, down, autoneg, 802.1q>

        MTU=1514, native vlan=1, MAC=00:d0:68:15:fd:3d, downtime
238h55m44s

        Requested: media AUTO, speed AUTO, duplex AUTO, fctl OFF,

                 throughput 0

        RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)

        TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)

        NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)

        Bandwidth thresholds are not set.
```

When the high availability monitor is disabled for an unused interface, the output of the show interface command for that interface does not include "HAMON."

Through GUI

To disable the high availability monitor for unused interfaces by using the GUI, follow these steps:

1. Navigate to System > Network > Interfaces.
2. Select the interface for which the monitor must be disabled.
3. Click Open. The Modify Interface dialog box appears.
4. In HA Monitoring, select the OFF option.
5. Click OK.
6. Verify that, when the interface is selected, "HA Monitoring: OFF" appears in the details at the bottom of the page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Change an RPC node password

To communicate with other NetScaler appliances, each appliance requires knowledge of the other appliances, including how to authenticate on NetScaler appliance. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. One RPC node exists on each NetScaler appliance and stores information, such as the IP addresses of the other NetScaler appliance and the passwords used for authentication. The NetScaler appliance that contacts the other NetScaler appliance checks the password within the RPC node.

For enhanced security, we recommend you to enable the **Secure** and **Validate Server Certificate** options on RPC nodes. When you enable the **Secure** option, NetScaler encrypts all the RPC communication sent from one NetScaler to other NetScaler thus securing the RPC communication. This secure communication uses the port number 3008. If the firewall between the NetScaler appliances blocks the port number 3008, unblock it and proceed. Otherwise, configuration synchronization and configuration propagation might fail.

The **Validate Server Certificate** option allows server certificate validation for RPC communication such as Configuration Synchronization or Configuration Propagation between the nodes. To validate the server certificate, the CA `/nsconfig/ssl/certs/ca.pem` file must be configured. Therefore, configure the CA file `/nsconfig/ssl/certs/ca.pem` with the peer CA certificate, which is used to sign the server certificate for the `nsrpcs-127.0.0.1-3008` service.

NOTE:

After you upgrade a NetScaler appliance to release 13.1 build 33.x or later from one of the following builds, the `secure` option for the RPC node is enabled or disabled on the basis of the TLS 1.2 setting (enabled or disabled) present for the internal RPCS and KRPCS services.

- Release 13.0 build 64.35 or earlier
- Release 12.1 build 61.18 or earlier

The RPC communication is encrypted between the NetScaler nodes of the following setups if the `secure` option is enabled:

- High availability
- Cluster
- GSLB

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The `secure` option uses secure protocol TLS1.2 and port numbers 3008 and 3009 for the RPC connection between the NetScaler nodes.
For ensuring secure RPC communication, Citrix® recommends performing the following operations before upgrading these setups:

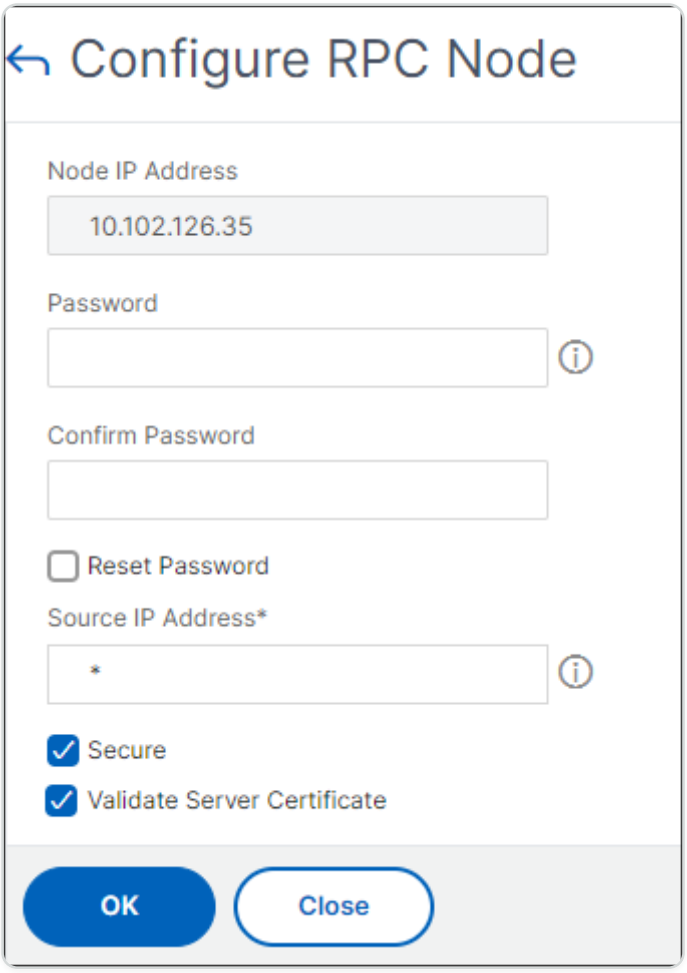
- TLS 1.2 must be enabled for the internal RPCS and KRPCS services:
  - `nsrpcs-127.0.0.1-3008`
  - `nskrpcs-127.0.0.1-3009`
  - `nsrpcs-::1l-3008`
- 3008 and 3009 must be unblocked in firewalls between the NetScaler nodes.

You can enable or disable the `secure` option using the NetScaler CLI or the GUI.

To change an RPC node password by using the GUI

1. Navigate to **System** > **Network** > **RPC**.
2. In the **RPC** pane, select the node and then click **Edit**.
3. In **Configure RPC Node**, type the new password.
4. In **Source IP Address**, type the existing node's IP address to be used to communicate with the peer system node.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Select **Secure** and **Validate Server Certificate**. Click **OK**.

To change an RPC node password by using the CLI

At the command line, type the following commands:

```
set ns rpcNode <IPAddress> {-password} [-secure ( YES | NO )] [-
validateCert (YES | NO)]

show ns rpcNode
```

Example:

```
> set ns rpcNode 192.0.2.4 -password mypassword -secure YES -validateCert
YES

 Done

> show rpcNode
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
.

.

.

 IPAddress:  192.0.2.4 Password:  d336004164d4352ce39e

     SrcIP:  *           Secure:  ON

     SrcIP:  *           validateCert:  YES

Done

>
```

Configure a FIPS appliance for the first time

NOTE

- FIPS FAQ can be found here: FIPS FAQ.

A certificate-key pair is required for HTTPS access to the configuration utility and for secure remote procedure calls. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. One RPC node exists on each appliance. This node stores the password, which is checked against the one provided by the contacting appliance. To communicate with other NetScaler appliances, each appliance requires knowledge of the other appliances, including how to authenticate on the other appliance. RPC nodes maintain this information, which includes the IP addresses of the other NetScaler appliances and the passwords used to authenticate on each.

On a NetScaler MPX appliance virtual appliance, a certificate-key pair is automatically bound to the internal services. On a FIPS appliance, a certificate-key pair must be imported into the hardware security module (HSM) of a FIPS card. To do so, you must configure the FIPS card, create a certificate-key pair, and bind it to the internal services.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure secure HTTPS by using the CLI

To configure secure HTTPS by using the CLI, follow these steps

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see one of the following links:
   - For MPX: Configure the HSM.
   - For SDX: Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance.
2. If the appliance is part of a high availability setup, enable the SIM. For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:

   ```
   import ssl fipskey serverkey -key ns-server.key -inform PEM
   ```
4. Add a certificate-key pair. At the command prompt, type:

   ```
   add certkey server -cert ns-server.cert -fipskey serverkey
   ```
5. Bind the certificate-key created in the previous step to the following internal services. At the command prompt, type:

   ```
   bind ssl service nshttps-127.0.0.1-443 -certkeyname server
   ```

   ```
   bind ssl service nshttps-::11-443 -certkeyname server
   ```

Configure secure HTTPS by using the GUI

To configure secure HTTPS by using the GUI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see one of the following links:
   - For MPX: Configure the HSM.
   - For SDX: Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. If the appliance is part of a high availability setup, enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, see the Import an existing FIPS key section.
4. Navigate to **Traffic Management > SSL > Certificates**.
5. In the details pane, click Install.
6. In the Install Certificate dialog box, type the certificate details.
7. Click Create, and then click Close.
8. Navigate to **Traffic Management > Load Balancing > Services**.
9. In the details pane, on the Action tab, click Internal Services.
10. Select `nshttps-127.0.0.1-443` from the list, and then click Open.
11. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
12. Select `nshttps-::11-443` from the list, and then click Open.
13. On the SSL Settings tab, in the Available pane, select the certificate created in step 7, click Add, and then click OK.
14. Click OK.

Configure secure RPC by using the CLI

To configure secure RPC by using the CLI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see one of the following links:
   - For MPX: Configure the HSM.
   - For SDX: Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance.
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, see Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. At the command prompt, type:

   ```
   import ssl fipskey serverkey -key ns-server.key -inform PEM
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Add a certificate-key pair. At the command prompt, type:

   ```
   add certkey server -cert ns-server.cert -fipskey serverkey
   ```

5. Bind the certificate-key pair to the following internal services. At the command prompt, type:

   ```
   bind ssl service nsrpcs-127.0.0.1-3008 -certkeyname server
   ```

   ```
   bind ssl service nskrpcs-127.0.0.1-3009 -certkeyname server
   ```

   ```
   bind ssl service nsrpcs-::1l-3008 -certkeyname server
   ```

6. Enable secure RPC mode. At the command prompt, type:

   ```
   set ns rpcnode \<IP address\> -secure YES
   ```

   For more information about changing an RPC node password, see Change an RPC node password.

Configure secure RPC by using the GUI

To configure secure RPC by using the GUI, follow these steps:

1. Initialize the hardware security module (HSM) on the FIPS card of the appliance. For information about initializing the HSM, see one of the following links:
   - For MPX: Configure the HSM.
   - For SDX: Configure the HSM for an instance on an SDX 14030/14060/14080 FIPS appliance.
2. Enable the secure information system (SIM). For information about enabling the SIM on the primary and secondary appliances, Configure FIPS appliances in a high availability setup.
3. Import the FIPS key into the HSM of the FIPS card of the appliance. For more information about importing a FIPS key, the Import an existing FIPS key section.
4. Navigate to **Traffic Management > SSL > Certificates**.
5. In the details pane, click **Install**.
6. In the **Install Certificate** dialog box, type the certificate details.
7. Click **Create**, and then click **Close**.
8. Navigate to **Traffic Management > Load Balancing > Services**.
9. In the details pane, on the **Action** tab, click **Internal Services**.
10. Select `nsrpcs-127.0.0.1-3008` from the list, and then click **Open**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

11. On the **SSL Settings** tab, in the **Available** pane, select the certificate created in step 7, click **Add**, and then click **OK**.
12. Select `nskrpcs-127.0.0.1-3009` from the list, and then click **Open**.
13. On the **SSL Settings** tab, in the **Available** pane, select the certificate created in step 7, click **Add**, and then click **OK**.
14. Select `nsrpcs-::11-3008` from the list, and then click **Open**.
15. On the **SSL Settings** tab, in the **Available** pane, select the certificate created in step 7, click **Add**, and then click **OK**.
16. Click **OK**.
17. Navigate to **System > Network > RPC**.
18. In the details pane, select the IP address, and click **Open**.
19. In the **Configure RPC Node** dialog box, select **Secure**.
20. Click **OK**.

Common network topologies

As described in the "Physical deployment mode" section in Where does a NetScaler appliance fit in the network?, you can deploy the NetScaler appliance either inline between the clients and servers or in one-arm mode. Inline mode uses a two-arm topology, which is the most common type of deployment.

Set up a common two-arm topology

In a two-arm topology, one network interface is connected to the client network and another network interface is connected to the server network, ensuring that all traffic flows through the appliance. This topology might require you to reconnect your hardware and also might result in a momentary downtime. The basic variations of two-arm topology are multiple subnets, typically with the appliance on a public subnet and the servers on a private subnet, and transparent mode, with both the appliance and the servers on the public network.

Set up a simple two-arm multiple subnet topology

One of the most commonly used topologies has the NetScaler appliance inline between the clients and the servers, with a virtual server configured to handle the client requests. This configuration is

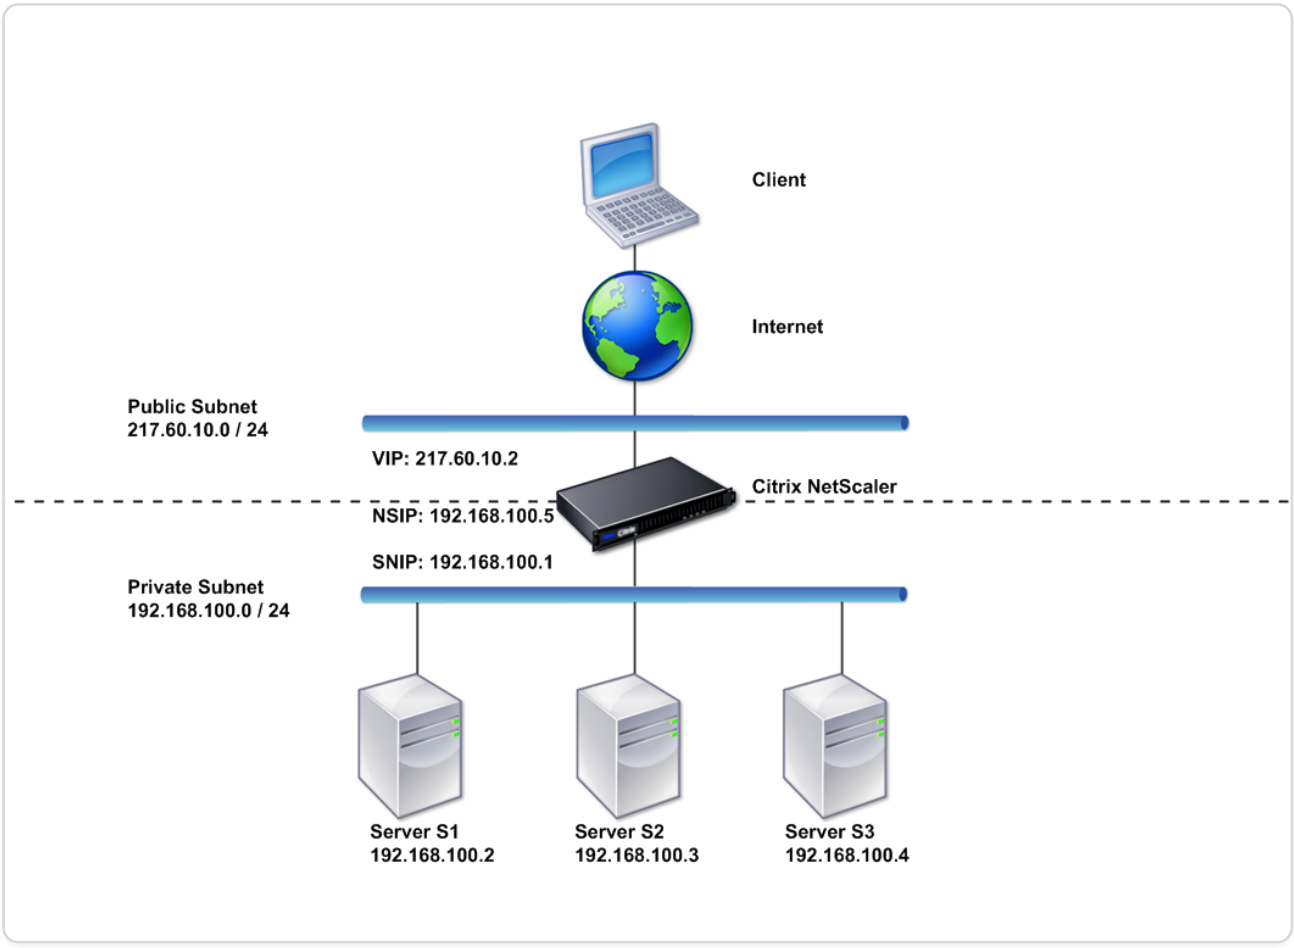
© 1997–2026 Citrix Systems, Inc. All rights reserved.

used when the clients and servers reside on different subnets. In most cases, the clients and servers reside on public and private subnets, respectively.

For example, consider an appliance deployed in two-arm mode for managing servers S1, S2, and S3, with a virtual server of type HTTP configured on the appliance, and with HTTP services running on the servers. The servers are on a private subnet and a SNIP is configured on the appliance to communicate with the servers. The Use SNIP (USNIP) option must be enabled on the appliance so that it uses the SNIP instead of the MIP.

As shown in the following figure, the VIP is on public subnet 217.60.10.0, and the NSIP, the servers, and the SNIP are on private subnet 192.168.100.0/24.

Figure 1. Topology Diagram for Two-Arm Mode, Multiple Subnets



To deploy a NetScaler appliance in two-arm mode with multiple subnets, follow these steps:

1. Configure the NSIP and default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Configure the SNIP, as described in Configuring Subnet IP Addresses.
3. Enable the USNIP option, as described in To enable or disable USNIP mode section.

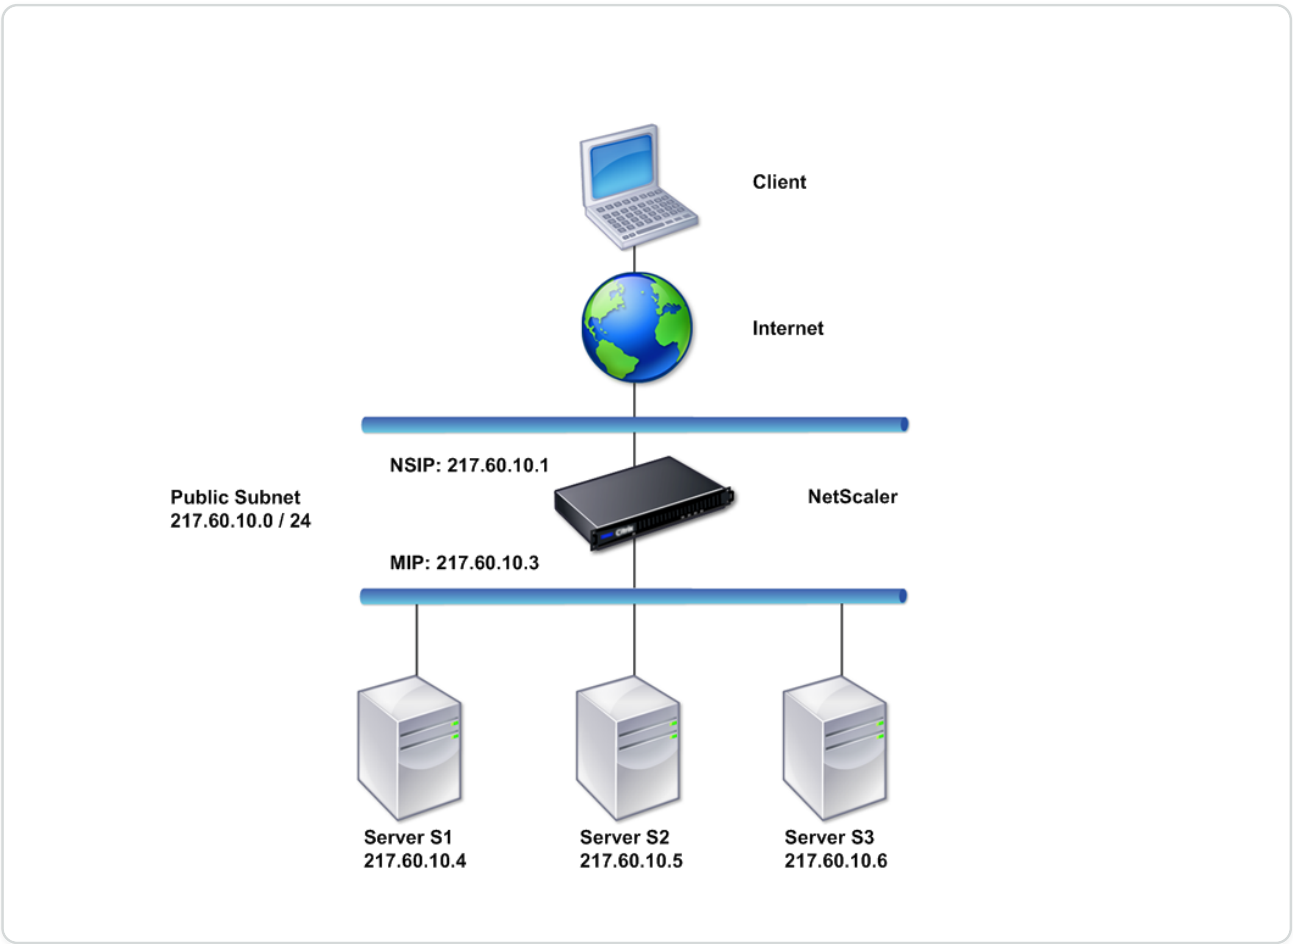
© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.
5. Connect one of the network interfaces to a private subnet and the other interface to a public subnet.

Set up a simple two-arm transparent topology

Use transparent mode if the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them. In the example shown in the following figure, a NetScaler appliance is placed between the client and the server, so the traffic must pass through the appliance. You must enable L2 mode for bridging the packets. The NSIP and MIP are on the same public subnet, 217.60.10.0/24.

Figure 2. Topology Diagram for Two-Arm, Transparent Mode



To deploy a NetScaler appliance in two-arm, transparent mode, follow these steps

1. Configure the NSIP and default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Enable L2 mode, as described in Enabling and Disabling Layer 2 Mode.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Configure the default gateway of the managed servers as the MIP.
4. Connect the network interfaces to the appropriate ports on the switch.

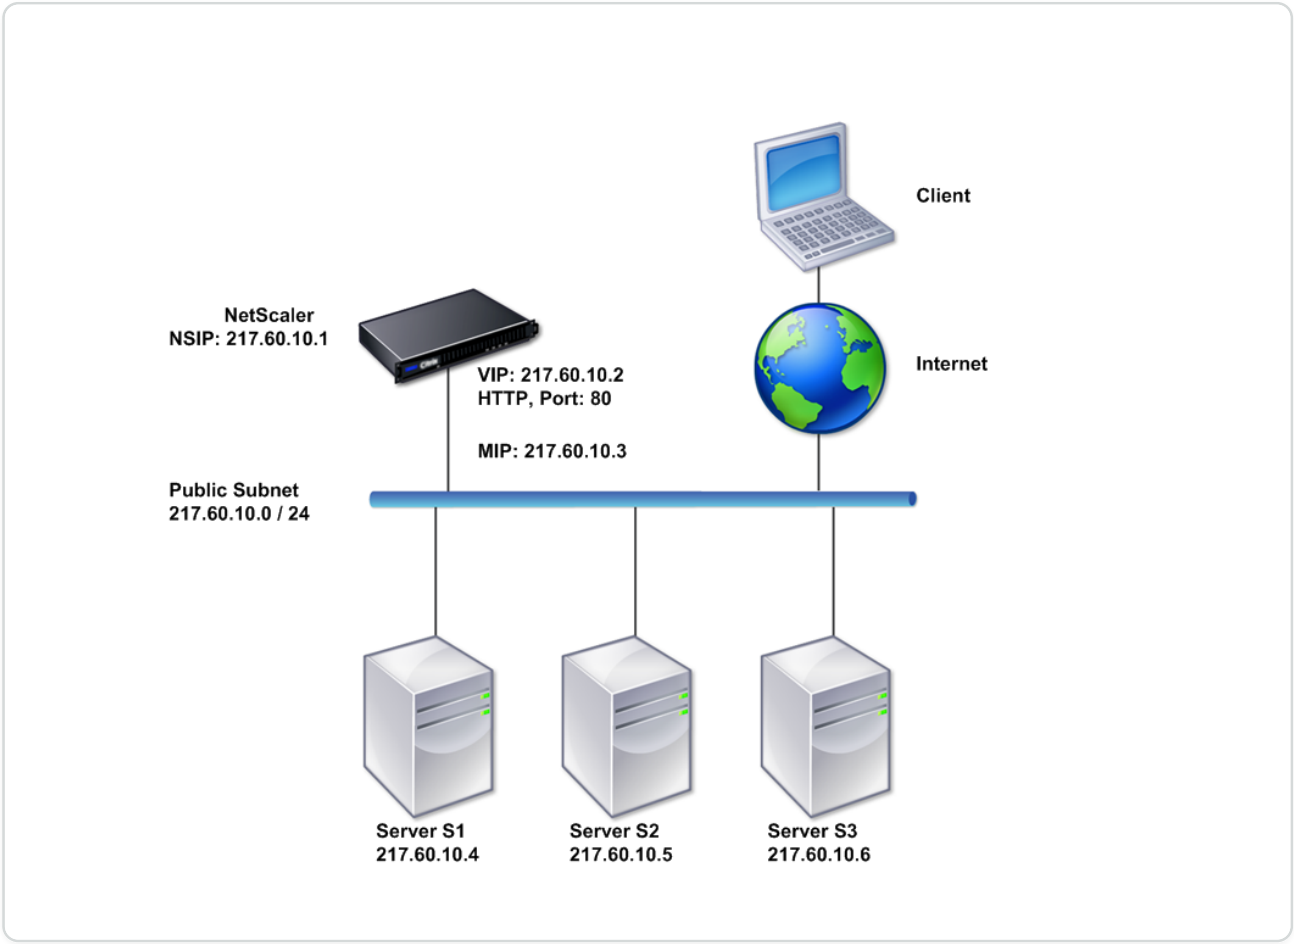
Set up common one-arm topologies

The two basic variations of one-arm topology are with a single subnet and with multiple subnets.

Set up a simple one-arm single subnet topology

You can use a one-arm topology with a single subnet when the clients and servers reside on the same subnet. For example, consider a NetScaler appliance deployed in one-arm mode for managing servers S1, S2, and S3. A virtual server of type HTTP is configured on an ADC appliance, and HTTP services are running on the servers. As shown in the following figure, the NetScaler IP address (NSIP), the Mapped IP address (MIP), and the server IP addresses are on the same public subnet, 217.60.10.0/24.

Figure 3. Topology Diagram for One-Arm Mode, Single Subnet



To deploy a NetScaler appliance in one-arm mode with a single subnet, follow these steps:

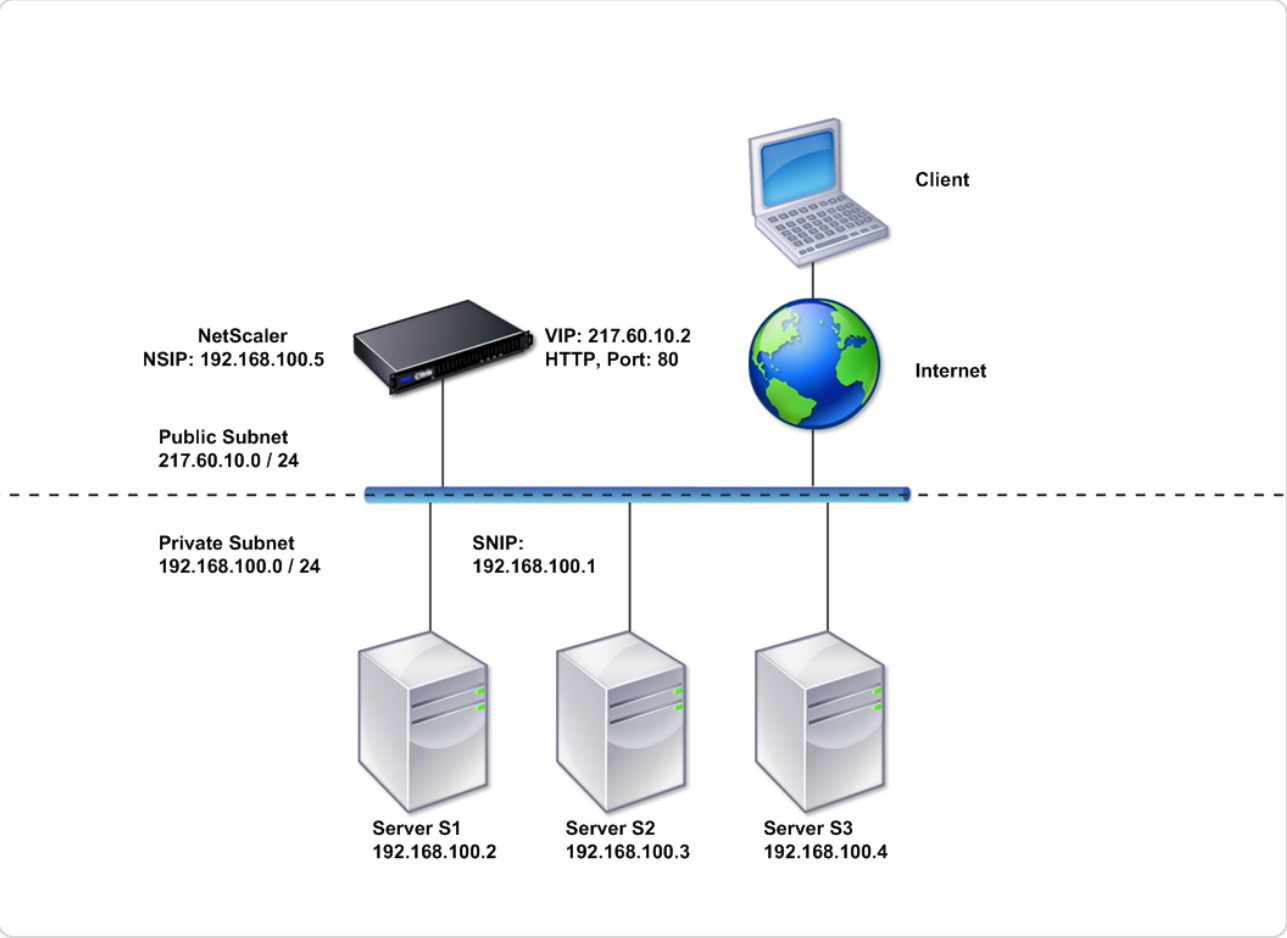
© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Configure the NSIP and the default gateway, as described in, as described in Configuring the NetScaler IP Address (NSIP).
2. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.
3. Connect one of the network interfaces to the switch.

Set up a simple one-arm multiple subnet topology

You can use a one-arm topology with multiple subnets when the clients and servers reside on the different subnets. For example, consider a NetScaler appliance deployed in one-arm mode for managing servers S1, S2, and S3, with the servers connected to switch SW1 on the network. A virtual server of type HTTP is configured on the appliance, and HTTP services are running on the servers. These three servers are on the private subnet, so a subnet IP address (SNIP) is configured to communicate with them. The Use Subnet IP address (USNIP) option must be enabled so that the appliance uses the SNIP instead of a MIP. As shown in the following figure, the virtual IP address (VIP) is on public subnet 217.60.10.0/24; the NSIP, SNIP, and the server IP addresses are on private subnet 192.168.100.0/24.

Figure 4. Topology Diagram for One-Arm Mode, Multiple Subnets



© 1997–2026 Citrix Systems, Inc. All rights reserved.

To deploy a NetScaler appliance in one-arm mode with multiple subnets, follow these steps:

1. Configure the NSIP and the default gateway, as described in Configuring the NetScaler IP Address (NSIP).
2. Configure the SNIP and enable the USNIP option, as described in Configuring Subnet IP Addresses.
3. Configure the virtual server and the services, as described in Creating a Virtual Server section and Configuring Services section.
4. Connect one of the network interfaces to the switch.

System management settings

Once your initial configuration is in place, you can configure settings to define the behavior of the NetScaler appliance and facilitate connection management. You have a number of options for handling HTTP requests and responses. Routing, bridging, and MAC based forwarding modes are available for handling packets not addressed to the NetScaler appliance. You can define the characteristics of your network interfaces and can aggregate the interfaces. To prevent timing problems, you can synchronize the Citrix clock with a Network Time Protocol (NTP) server. The NetScaler appliance can operate in various DNS modes, including as an authoritative domain name server (ADNS). You can set up SNMP for system management and customize syslog logging of system events. Before deployment, verify that your configuration is complete and correct.

System settings

Configuration of system settings includes basic tasks such as configuring HTTP ports to enable connection keep-alive and server offload, setting the maximum number of connections for each server, and setting the maximum number of requests per connection. You can enable client IP address insertion for situations in which a proxy IP address is not suitable, and you can change the HTTP cookie version.

You can also configure a NetScaler appliance to open FTP connections on a controlled range of ports instead of ephemeral ports for data connections. This improves security, because opening all ports on the firewall is insecure. You can set the range anywhere from 1,024 to 64,000.

Before deployment, go through the verification checklists to verify your configuration. To configure HTTP parameters and the FTP port range, use the NetScaler GUI.

You can modify the types of HTTP parameters described in the following table.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Parameter Type: HTTP Port Information

Specifies: The web server HTTP ports used by your managed servers. If you specify the ports, the appliance performs request switching for any client request that has a destination port matching a specified port.

Note: If an incoming client request is not destined for a service or a virtual server that is specifically configured on the appliance, the destination port in the request must match one of the globally configured HTTP ports. This allows the appliance to perform connection keep-alive and server off-load.

Parameter Type: Limits

Specifies: The maximum number of connections to each managed server, and the maximum number of requests sent over each connection. For example, if you set Max Connections to 500, and the appliance is managing three servers, it can open a maximum of 500 connections to each of the three servers. By default, the appliance can create an unlimited number of connections to any of the servers it manages. To specify an unlimited number of requests per connection, set Max Requests to 0.

Note: If you are using the Apache HTTP server, you must set Max Connections equal to the value of the MaxClients parameter in the Apache httpd.conf file. Setting this parameter is optional for other web servers.

Parameter Type: Client IP Insertion

Specifies: Enable/disable insertion of the client's IP address into the HTTP request header. You can specify a name for the header field in the adjacent text box. When a web server managed by an appliance receives a subnet IP address, the server identifies it as the client’s IP address. Some applications need the client’s IP address for logging purposes or to dynamically determine the content to be served by the web server.

You can enable insertion of the actual client IP address into the HTTP header request sent from the client to one, some, or all servers managed by the appliance. You can then access the inserted address through a minor modification to the server (using an Apache module, ISAPI interface, or NSAPI interface).

Parameter Type: Cookie Version

Specifies: The HTTP cookie version to use when COOKIEINSERT persistence is configured on a virtual server. The default, version 0, is the most common type on the Internet. Alternatively, you can specify version 1.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Parameter Type: Requests/Responses

Specifies: Options for handling certain types of requests, and enable/disable logging of HTTP error responses.

Parameter Type: Server Header Insertion

Specifies: Insert a server header in NetScaler-generated HTTP responses.

To configure HTTP parameters by using the GUI, follow these steps:

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Settings**, click **Change HTTP parameters**.
3. In the **Configure HTTP parameters** dialog box, specify values for some or all of the parameters that appear under the headings listed in the table above.
4. Click **OK**.

To set the FTP port range by using the GUI, follow these steps:

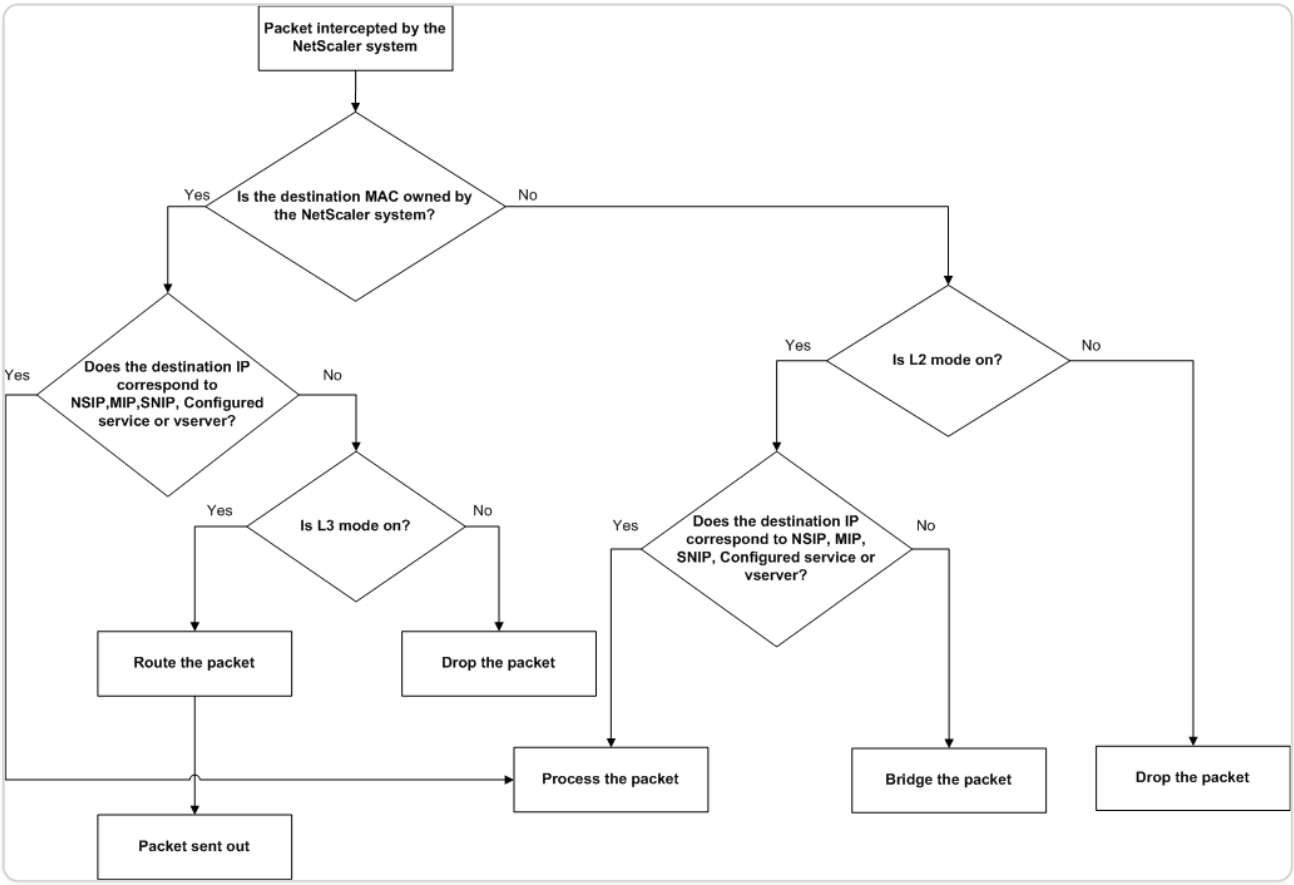
1. In the navigation pane, expand **System**, and then click **Settings**
2. In the details pane, under **Settings**, click **Change global system settings**.
3. Under **FTP Port Range,** in the **Start Port** and **End Port** text boxes, type the lowest and highest port numbers, respectively, for the range you want to specify (for example, 5000 and 6000).
4. Click **OK**.

Packet forwarding modes

The NetScaler appliance can either route or bridge packets that are not destined for an IP address owned by the appliance (that is, the IP address is not the NSIP, a MIP, a SNIP, a configured service, or a configured virtual server). By default, L3 mode (routing) is enabled and L2 mode (bridging) is disabled, but you can change the configuration. The following flow chart shows how the appliance evaluates packets and either processes, routes, bridges, or drops them.

Figure 1. Interaction between Layer 2 and Layer 3 Modes

© 1997–2026 Citrix Systems, Inc. All rights reserved.



An appliance can use the following modes to forward the packets it receives:

- Layer 2 (L2) Mode
- Layer 3 (L3) Mode
- MAC-Based Forwarding Mode

Enable and disable layer 2 mode

Layer 2 mode controls the Layer 2 forwarding (bridging) function. You can use this mode to configure a NetScaler appliance to behave as a Layer 2 device and bridge the packets that are not destined for it. When this mode is enabled, packets are not forwarded to any of the MAC addresses, because the packets can arrive on any interface of the appliance and each interface has its own MAC address.

With Layer 2 mode disabled (which is the default), the appliance drops packets that are not destined for one of its MAC address. If another Layer 2 device is installed in parallel with the appliance, Layer 2 mode must be disabled to prevent bridging (Layer 2) loops. You can use the configuration utility or the command line to enable Layer 2 mode.

Note: The appliance does not support the Spanning Tree Protocol. To avoid loops, if you enable L2 mode, do not connect two interfaces on the appliance to the same broadcast domain.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable or disable Layer 2 mode by using the CLI

At the command prompt, type the following commands to enable/disable Layer 2 mode and verify that it has been enabled/disabled:

- enable ns mode \<Mode\>
- disable ns mode \<Mode\>
- show ns mode

Examples

```
> enable ns mode l2

Done

> show ns mode

Mode Acronym Status

------- ------- ------

1) Fast Ramp FR ON

2) Layer 2 mode L2 ON

.

.

.

Done

>

> disable ns mode l2

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> show ns mode

Mode Acronym Status

------- ------- ------

1) Fast Ramp FR ON

2) Layer 2 mode L2 OFF

.

.

.

Done

>
```

To enable or disable Layer 2 mode by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes** and **Features**, click **Configure modes**.
3. In the **Configure Modes** dialog box, to enable Layer 2 mode, select the **Layer 2 Mode** check box. To disable Layer 2 mode, clear the check box.
4. Click **OK**. The **Enable/Disable Mode(s)?** message appears in the details pane.
5. Click **Yes**.

Enable and disable layer 3 mode

Layer 3 mode controls the Layer 3 forwarding function. You can use this mode to configure a NetScaler appliance to look at its routing table and forward packets that are not destined for it. With Layer 3 mode enabled (which is the default), the appliance performs route table lookups and forwards all packets that are not destined for any appliance-owned IP address. If you disable Layer 3 mode, the appliance drops these packets.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable or disable Layer 3 mode by using the CLI

At the command prompt, type the following commands to enable/disable Layer 3 mode and verify that it has been enabled/disabled:

- enable ns mode \<Mode\>
- disable ns mode \<Mode\>
- show ns mode

Examples

```
> enable ns mode l3

Done

> show ns mode

Mode Acronym Status

------- ------- ------

1) Fast Ramp FR ON

2) Layer 2 mode L2 OFF

.

.

.

9) Layer 3 mode (ip forwarding) L3 ON

.

.

.

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
>

> disable ns mode l3

Done

> show ns mode

Mode Acronym Status

------- ------- ------

1) Fast Ramp FR ON

2) Layer 2 mode L2 OFF

.

.

.

9) Layer 3 mode (ip forwarding) L3 OFF

.

.

.

Done

>
```

Enable or disable Layer 3 mode by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes and Features**, click **Configure Modes**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. In the **Configure Modes** dialog box, to enable Layer 3 mode, select the **Layer 3 Mode (IP Forwarding)** check box. To disable Layer 3 mode, clear the check box.
4. Click **OK**. The **Enable/Disable Mode(s)?** message appears in the details pane.
5. Click **Yes**.

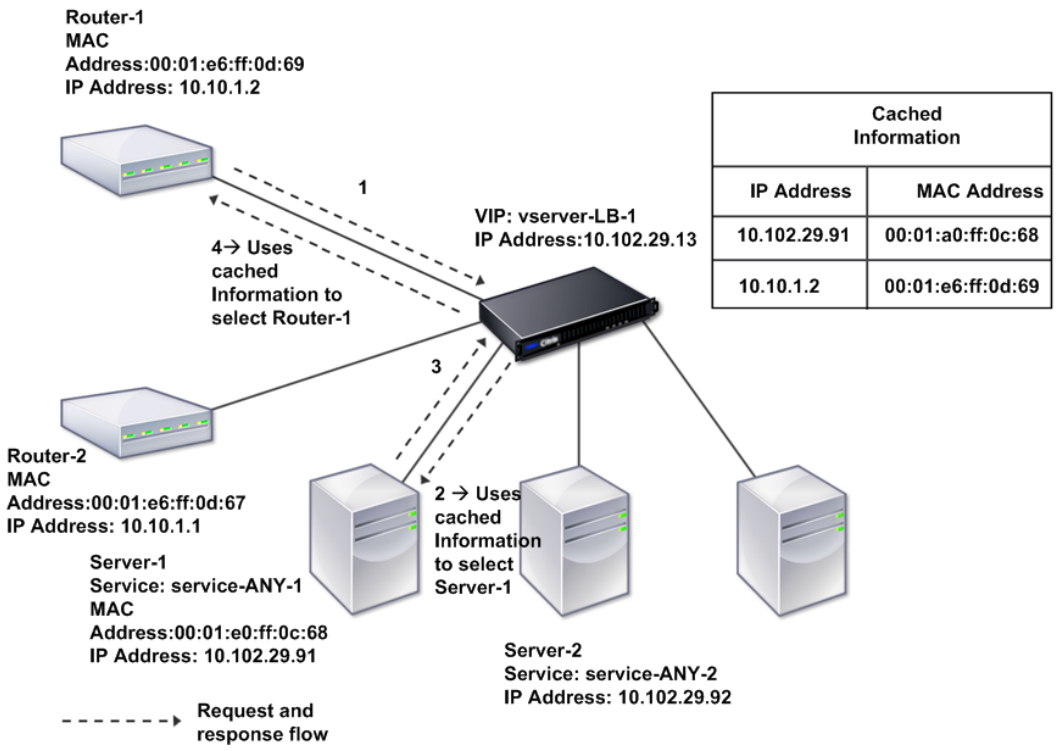
Enable and disable MAC-based forwarding mode

You can use MAC-based forwarding to process traffic more efficiently and avoid multiple-route or ARP lookups when forwarding packets, because the NetScaler appliance remembers the MAC address of the source. To avoid multiple lookups, the appliance caches the source MAC address of every connection for which it performs an ARP lookup, and it returns the data to the same MAC address.

MAC-based forwarding is useful when you use VPN devices because the appliance ensures that all traffic flowing through a particular VPN passes through the same VPN device.

The following figure shows the process of MAC-based forwarding.

Figure 2. MAC-based Forwarding Process



When MAC-based forwarding is enabled, the appliance caches the MAC address of:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server responds through an appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when an appliance initiates a connection, it uses the route and ARP tables for the lookup function. To enable MAC-based forwarding, use the configuration utility or the command line.

Some deployments require the incoming and outgoing paths to flow through different routers. In these situations, MAC-based forwarding breaks the topology design. For a global server load balancing (GSLB) site that requires the incoming and outgoing paths to flow through different routers, you must disable MAC-based forwarding and use the appliance's default router as the outgoing router.

With MAC-based forwarding disabled and Layer 2 or Layer 3 connectivity enabled, a route table can specify separate routers for outgoing and incoming connections. To disable MAC-based forwarding, use the configuration utility or the command line.

Enable or disable MAC-based forwarding by using the CLI

At the command prompt, type the following commands to enable/disable MAC-based forwarding mode and verify that it has been enabled/disabled:

- <enable ns mode \<Mode\>
- <disable ns mode \<Mode\>
- <show ns mode **Example**

```
> enable ns mode mbf

 Done

> show ns mode

     Mode                      Acronym          Status

     -------                   -------          ------
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
 1)  Fast Ramp                  FR              ON

 2)  Layer 2 mode               L2              OFF

 .

 .

 .

 6)  MAC-based forwarding       MBF             ON

 .

 .

 .

 Done

>

> disable ns mode mbf

 Done

> show ns mode

     Mode                       Acronym         Status

     -------                    -------         ------

 1)  Fast Ramp                  FR              ON

 2)  Layer 2 mode               L2              OFF

 .

 .
```

```
  .

  6)  MAC-based forwarding        MBF              OFF

  .

  .

  .

  Done

 >
```

To enable or disable MAC-based forwarding by using the GUI

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes and Features** group, click **Configure modes**.
3. In the **Configure Modes** dialog box, to enable MAC-based forwarding mode, select the **MAC Based Forwarding** check box. To disable MAC-based forwarding mode, clear the check box.
4. Click **OK**. The **Enable/Disable Mode(s)?** message appears in the details pane.
5. Click **Yes**.

Network interfaces

The NetScaler interfaces are numbered in slot/port notation. In addition to modifying the characteristics of individual interfaces, you can configure virtual LANs to restrict traffic to specific groups of hosts. You can also aggregate links into high-speed channels.

Virtual LANs

The NetScaler appliance supports (Layer 2) port and IEEE802.1Q tagged virtual LANs (VLANs). VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface to belong to multiple VLANs by using IEEE 802.1q tagging.

You can bind your configured VLANs to IP subnets. The ADC appliance (if it is configured as the default router for the hosts on the subnets) then performs IP forwarding between these VLANs.

The NetScaler appliance supports the following types of VLANs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Default VLAN

  By default, the network interfaces on a NetScaler appliance are included in a single, port-based VLAN as untagged network interfaces. This default VLAN has a VID of 1 and exists permanently. It cannot be deleted, and its VID cannot be changed.

- Port-Based VLANs

  A set of network interfaces that share a common, exclusive, Layer 2 broadcast domain define the membership of a port-based VLAN. You can configure multiple port-based VLANs. When you add an interface to a new VLAN as an untagged member, it is automatically removed from the default VLAN.

- Tagged VLAN

  A network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of only one VLAN (its native VLAN). The untagged network interface forwards the frames for the native VLAN as untagged frames. A tagged network interface can be a part of more than one VLAN. When you configure tagging, be sure that both ends of the link have matching VLAN settings. You can use the configuration utility to define a tagged VLAN (nsvlan) that can have any ports bound as tagged members of the VLAN. Configuring this VLAN requires a reboot of the ADC appliance and therefore must be done during initial network configuration.

Link aggregate channels

Link aggregation combines incoming data from multiple ports into a single high speed link. Configuring the link aggregate channel increases the capacity and availability of the communication channel between a NetScaler appliance and other connected devices. An aggregated link is also referred to as a channel.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. A network interface can be bound to only one channel. Binding a network interface to a link aggregate channel changes the VLAN configuration. That is, binding network interfaces to a channel removes them from the VLANs that they originally belonged to and adds them to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you have bound network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then you bind them to link aggregate channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them to VLAN 2.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Note: You can also use Link Aggregation Control Protocol (LACP) to configure link aggregation. For more information, see Configuring Link Aggregation by Using the Link Aggregation Control Protocol.

Clock synchronization

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network. NTP uses User Datagram Protocol (UDP) port 123 as its transport layer. Add NTP servers in the NTP configuration file so that the appliance periodically gets updates from these servers.

If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site at `<http://www.ntp.org>`.

To configure clock synchronization on your appliance, follow these steps:

1. Log on to the command line and enter the shell command.
2. At the shell prompt, copy the ntp.conf file from the /etc directory to the /nsconfig directory. If the file already exists in the /nsconfig directory, make sure that you remove the following entries from the ntp.conf file:

   `restrict localhost`

   `restrict 127.0.0.2`

   These entries are required only if you want to run the device as a time server. However, this feature is not supported on the NetScaler appliance.
3. Edit /nsconfig/ntp.conf by typing the IP address for the desired NTP server under the file's server and restrict entries.
4. Create a file named rc.netscaler in the /nsconfig directory, if the file does not already exist in the directory.
5. Edit /nsconfig/rc.netscaler by adding the following entry: `/bin/sh /etc/ntpd_ctl full_start`.

   This entry starts the ntpd service, and checks the ntp.conf file.

   If you do not want to forcibly sync the time when there is a large difference, you can set the date manually and then start ntpd again. You can check the time difference between the appliance and the time server, by running the following command in the shell:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
ntpdate -q <IP address or domain name of the NTP server>
```

6. Reboot the appliance to enable clock synchronization.

   Note: If you want to start time synchronization without restarting the appliance, enter one of the following commands at the shell prompt:

```
/usr/sbin/ntpd -c /nsconfig/ntp.conf -g -p /var/run/ntpd.pid -l /var/
log/ntpd.log &

or

/bin/sh /etc/ntpd_ctl full_start
```

DNS configuration

You can configure a NetScaler appliance to function as an Authoritative Domain Name Server (ADNS), DNS proxy server, End Resolver, or Forwarder. You can add DNS resource records such as SRV Records, AAAA Records, A Records, MX Records, NS Records, CNAME Records, PTR Records, and SOA Records. Also, the appliance can balance the load on external DNS servers.

A common practice is to configure an appliance as a forwarder. For this configuration, you need to add external name servers. After you have added the external servers, you should verify that your configuration is correct.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

When adding name servers, you can specify IP addresses or virtual IP addresses (VIPs). If you use IP addresses, the appliance load balances requests to the configured name servers in a round robin manner. If you use VIPs, you can specify any load balancing method.

Add a name server by using the CLI

At the command prompt, type the following commands to add a name server and verify the configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `<add dns nameServer \<IP\>`
- `<show dns nameServer \<IP\>`

Example

```
> add dns nameServer 10.102.29.10
 Done
> show dns nameServer 10.102.29.10
1)       10.102.29.10  -  State: DOWN
 Done
```

Add a name server by using the GUI

1. Navigate to **Traffic Management** > **DNS** > **Name Servers**.
2. In the details pane, click **Add**.
3. In the **Create Name Server** dialog box, select **IP Address**.
4. In the **IP Address** text box, type the IP address of the name server (for example, 10.102.29.10). If you are adding an external name server, clear the **Local** check box.
5. Click **Create**, and then click **Close**.
6. Verify that the name server you added appears in the **Name Servers** pane.

SNMP configuration

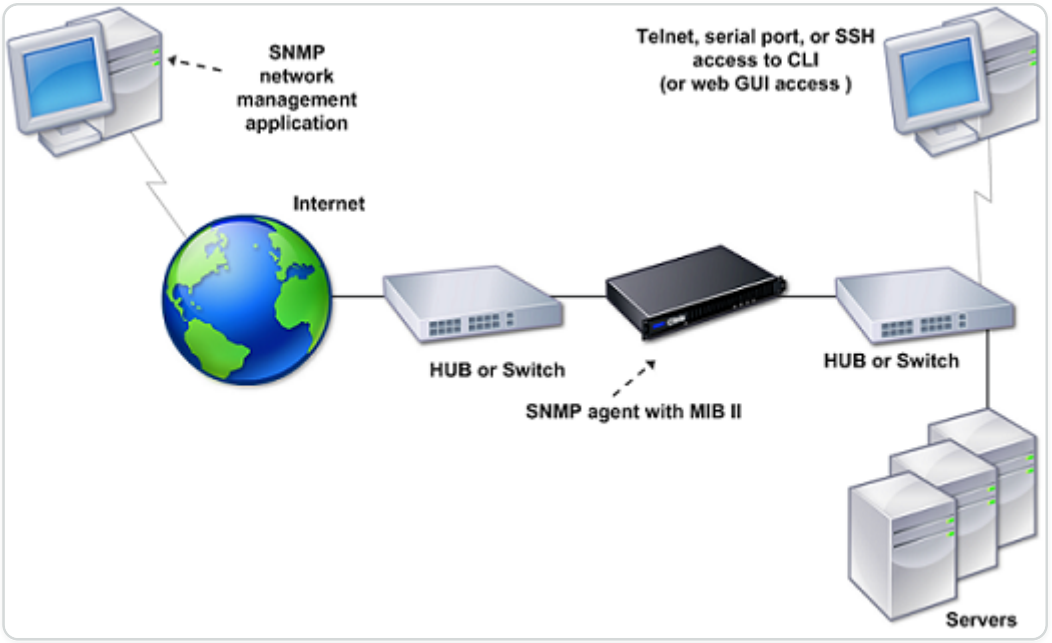
The Simple Network Management Protocol (SNMP) network management application, running on an external computer, queries the SNMP agent on the NetScaler appliance. The agent searches the management information base (MIB) for data requested by the network management application and sends the data to the application.

SNMP monitoring uses traps messages and alarms. SNMP traps messages are asynchronous events that the agent generates to signal abnormal conditions, which are indicated by alarms. For example, if you want to be informed when CPU utilization is above 90 percent, you can set up an

© 1997–2026 Citrix Systems, Inc. All rights reserved.

alarm for that condition. The following figure shows a network with a NetScaler appliance that has SNMP enabled and configured.

Figure 1. SNMP on the NetScaler appliance



The SNMP agent on a NetScaler appliance supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3). Because it operates in bilingual mode, the agent can handle SNMPv2 queries, such as Get-Bulk, and SNMPv1 queries. The SNMP agent also sends traps compliant with SNMPv2 and supports SNMPv2 data types, such as counter64. SNMPv1 managers (programs on other servers that request SNMP information from the ADC appliance) use the NS-MIB-smiv1.mib file when processing SNMP queries. SNMPv2 managers use the NS-MIB-smiv2.mib file.

The NetScaler appliance supports the following enterprise-specific MIBs:

- A subset of standard MIB-2 groups. Provides MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- A system enterprise MIB. Provides system-specific configuration and statistics.

To configure SNMP, you specify which managers can query the SNMP agent, add SNMP trap listeners that will receive the SNMP trap messages, and configure SNMP Alarms.

Add SNMP managers

You can configure a workstation running a management application that complies with SNMP version 1, 2, or 3 to access an appliance. Such a workstation is called an SNMP manager. If you do not specify an SNMP manager on the appliance, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

appliance accepts and responds to SNMP queries from only those specific IP addresses. When specifying the IP address of an SNMP manager, you can use the netmask parameter to grant access from entire subnets. You can add a maximum of 100 SNMP managers or networks. To add an SNMP manager by using the CLI

At the command prompt, type the following commands to add an SNMP manager and verify the configuration:

`add snmp manager <IPAddress> ... [-netmask <netmask>]` `show snmp manager <IPAddress>`

Example:

```
add snmp manager 10.102.29.5 -netmask 255.255.255.255

Done

show snmp manager 10.102.29.5

10.102.29.5 255.255.255.255

Done
```

To add an SNMP manager by using the GUI:

1. In the navigation pane, expand **System**, expand **SNMP**, and then click **Managers**.
2. In the details pane, click **Add**.
3. In the **Add SNMP Manager** dialog box, in the **IP Address** text box, type the IP address of the workstation running the management application (for example, 10.102.29.5).
4. Click **Create**, and then click **Close**.
5. Verify that the SNMP manager you added appears in the **Details** section at the bottom of the pane.

Add SNMP traps listeners

After configuring the alarms, you need to specify the trap listener to which the appliance will send the trap messages. Apart from specifying parameters like IP address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To add an SNMP trap listener by using the CLI

At the command prompt, type the following command to add an SNMP trap and verify that it has been added:

- `add snmp trap specific <IP>`
- `show snmp trap`

Example:

```
Trap type: SPECIFIC

Destination IP: 10.102.29.3

TD: 0

Destination Port: 162

Source IP: NetScaler IP

Version: V2

Min-Severity: -

AllPartition: DISABLED

Community: public
```

To add an SNMP trap listener by using the GUI

1. In the navigation pane, expand System, expand **SNMP**, and then click **Traps**.
2. In the details pane, click **Add**.
3. In the **Create SNMP Trap Destination** dialog box, in the **Destination IP Address** text box, type the IP address (for example, 10.102.29.3).
4. Click **Create** and then click **Close**.
5. Verify that the SNMP trap you added appears in the **Details** section at the bottom of the pane.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure SNMP alarms

You configure alarms so that the appliance generates a trap message when an event corresponding to one of the alarms occurs. Configuring an alarm consists of enabling the alarm and setting the severity level at which a trap is generated. There are five severity levels: Critical, Major, Minor, Warning, and Informational. A trap is sent only when the severity of the alarm matches the severity specified for the trap.

Some alarms are enabled by default. If you disable an SNMP alarm, the appliance will not generate trap messages when corresponding events occur. For example, if you disable the Login-Failure SNMP alarm, the appliance will not generate a trap message when a login failure occurs.

To enable or disable an alarm by using the CLI

At the command prompt, type the following commands to enable or disable an alarm and verify that it has been enabled or disabled:

- set snmp alarm \<trapName\> \[-state ENABLED | DISABLED \]
- show snmp alarm \<trapName\>

Example

```
set snmp alarm LOGIN-FAILURE -state ENABLED

Done

show snmp alarm LOGIN-FAILURE

Alarm Alarm Threshold Normal Threshold Time State Severity Logging

\----- -------------- --------------- ---- -------- --------- --------

LOGIN-FAILURE N/A N/A N/A ENABLED - ENABLED

Done
```

To set the severity of the alarm by using the CLI

At the command prompt, type the following commands to set the severity of the alarm and verify that the severity has been set correctly:

- `set snmp alarm <trapName> [-severity <severity>]`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `show snmp alarm <trapName>`

Example:

```
set snmp alarm LOGIN-FAILURE -severity Major

Done

show snmp alarm LOGIN-FAILURE

Alarm Alarm Threshold Normal Threshold Time State Severity Logging

\----- -------------- --------------- ---- -------- --------- --------

LOGIN-FAILURE N/A N/A N/A ENABLED Major ENABLED

Done
```

To configure alarms by using the GUI

1. In the navigation pane, expand **System**, expand SNMP, and then click **Alarms**.
2. In the details pane, select an alarm (for example, LOGIN-FAILURE), and then click **Open**.
3. In the **Configure SNMP Alarm** dialog box, to enable the alarm, select Enabled in the **State** drop-down list. To disable the alarm, select Disabled.
4. In the **Severity** drop-down list, select a severity option (for example, Major).
5. Click **OK**, and then click **Close**.
6. Verify that the parameters for the SNMP alarm you configured are correctly configured by viewing the **Details** section at the bottom of the pane.

Verify configuration

After you've finished configuring your system, complete the following checklists to verify your configuration.

Configuration checklist

- The build running is:
- There are no incompatibility issues. (Incompatibility issues are documented in the build's release notes.)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The port settings (speed, duplex, flow control, monitoring) are the same as the switch’s port.
- Enough SNIP IP addresses have been configured to support all server-side connections during peak times.
    - The number of configured SNIP IP addresses is:____
    - The expected number of simultaneous server connections is:

      \[\] 62,000 \[\] 124,000 \[\] Other____

Topology configuration checklist

The routes have been used to resolve servers on other subnets.

The routes entered are:

_____

- If the NetScaler appliance is in a public-private topology, reverse NAT has been configured.
- The failover (high availability) settings configured on the ADC appliance resolve in a one arm or two-arm configuration. All unused network interfaces have been disabled:

_____

- If the ADC appliance is placed behind an external load balancer, then the load balancing policy on the external load balancer is not "least connection".

  The load balancing policy configured on the external load balancer is:

  _____
- If the ADC appliance is placed in front of a firewall, the session time-out on the firewall is set to a value greater than or equal to 300 seconds.

  Note: The TCP idle connection timeout on a NetScaler appliance is 360 seconds. If the timeout on the firewall is also set to 300 seconds or more, then the appliance can perform TCP connection multiplexing effectively because connections will not be closed earlier.

  The value configured for the session time-out is: _____

Server configuration checklist

- "Keep-alive" has been enabled on all the servers.

  The value configured for the keep-alive time-out is: _____

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The default gateway has been set to the correct value. (The default gateway should either be a NetScaler appliance or upstream router.) The default gateway is:

  _____

- The server port settings (speed, duplex, flow control, monitoring) are the same as the switch port settings.

  _____

- If the Microsoft Internet Information Server is used, buffering is enabled on the server.
- If an Apache Server is used, the MaxConn (maximum number of connections) parameter is configured on the server and on the NetScaler appliance.

  The MaxConn (maximum number of connections) value that has been set is:

  _____

- If a Netscape Enterprise Server is used, the maximum requests per connection parameter is set on the NetScaler appliance. The maximum requests per connection value that has been set is:

  _____

Software features configuration checklist

- Does the Layer 2 mode feature need to be disabled? (Disable if another Layer 2 device is working in parallel with a NetScaler appliance.)

  Reason for enabling or disabling:

  _____

- Does the MAC-based forwarding feature need to be disabled? (If the MAC address used by return traffic is different, it should be disabled.)

  Reason for enabling or disabling:

  _____

- Does host-based reuse need to be disabled? (Is there virtual hosting on the servers?)

  Reason for enabling or disabling:

  _____

- Do the default settings of the surge protection feature need to be changed?

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Reason for changing or not changing:

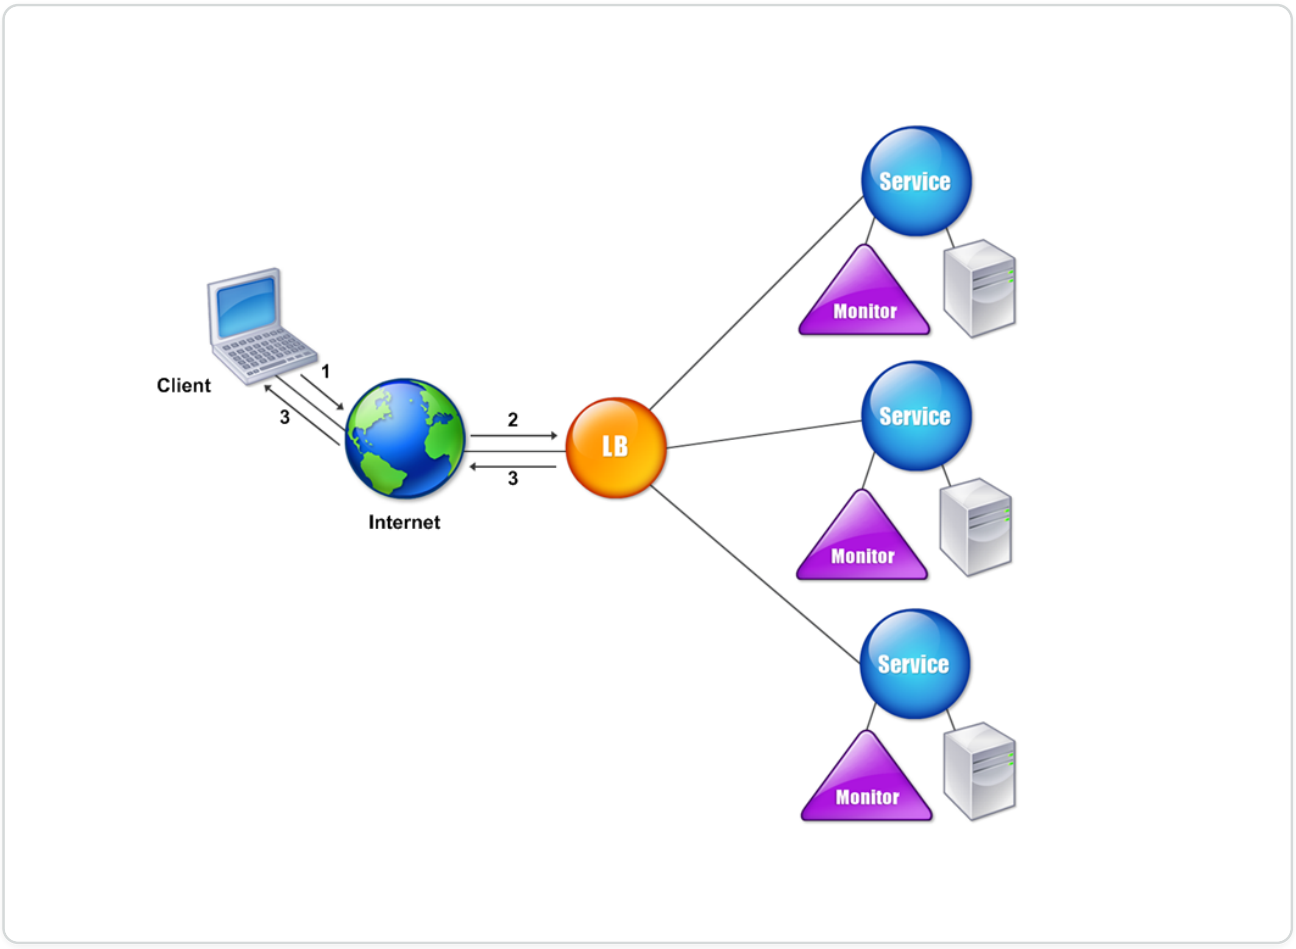
___

When a client initiates a connection to the server, a virtual server terminates the client connection and initiates a new connection with the selected server, or reuses an existing connection with the server, to perform load balancing. The load balancing feature provides traffic management from Layer 4 (TCP and UDP) through Layer 7 (FTP, HTTP, and HTTPS).

The NetScaler appliance uses a number of algorithms, called load balancing methods, to determine how to distribute the load among the servers. The default load balancing method is the Least Connections method.

A typical load balancing deployment consists of the entities described in the following figure.

Figure 1. Load Balancing Architecture



The entities function as follows:

- **Virtual server**. An entity that is represented by an IP address, a port, and a protocol. The virtual server IP address (VIP) is usually a public IP address. The client sends connection requests to this IP address. The virtual server represents a bank of servers.
- **Service**. A logical representation of a server or an application running on a server. Identifies the server's IP address, a port, and a protocol. The services are bound to the virtual servers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Server object**. An entity that is represented by an IP address. The server object is created when you create a service. The IP address of the service is taken as the name of the server object. You can also create a server object and then create services by using the server object.
- **Monitor**. An entity that tracks the health of the services. The appliance periodically probes the servers using the monitor bound to each service. If a server does not respond within a specified response timeout, and the specified number of probes fails, the service is marked DOWN. The appliance then performs load balancing among the remaining services.

Load balancing

To configure load balancing, you must first create services. Then, you create virtual servers and bind the services to the virtual servers. By default, the NetScaler appliance binds a monitor to each service. After binding the services, verify your configuration by making sure that all of the settings are correct.

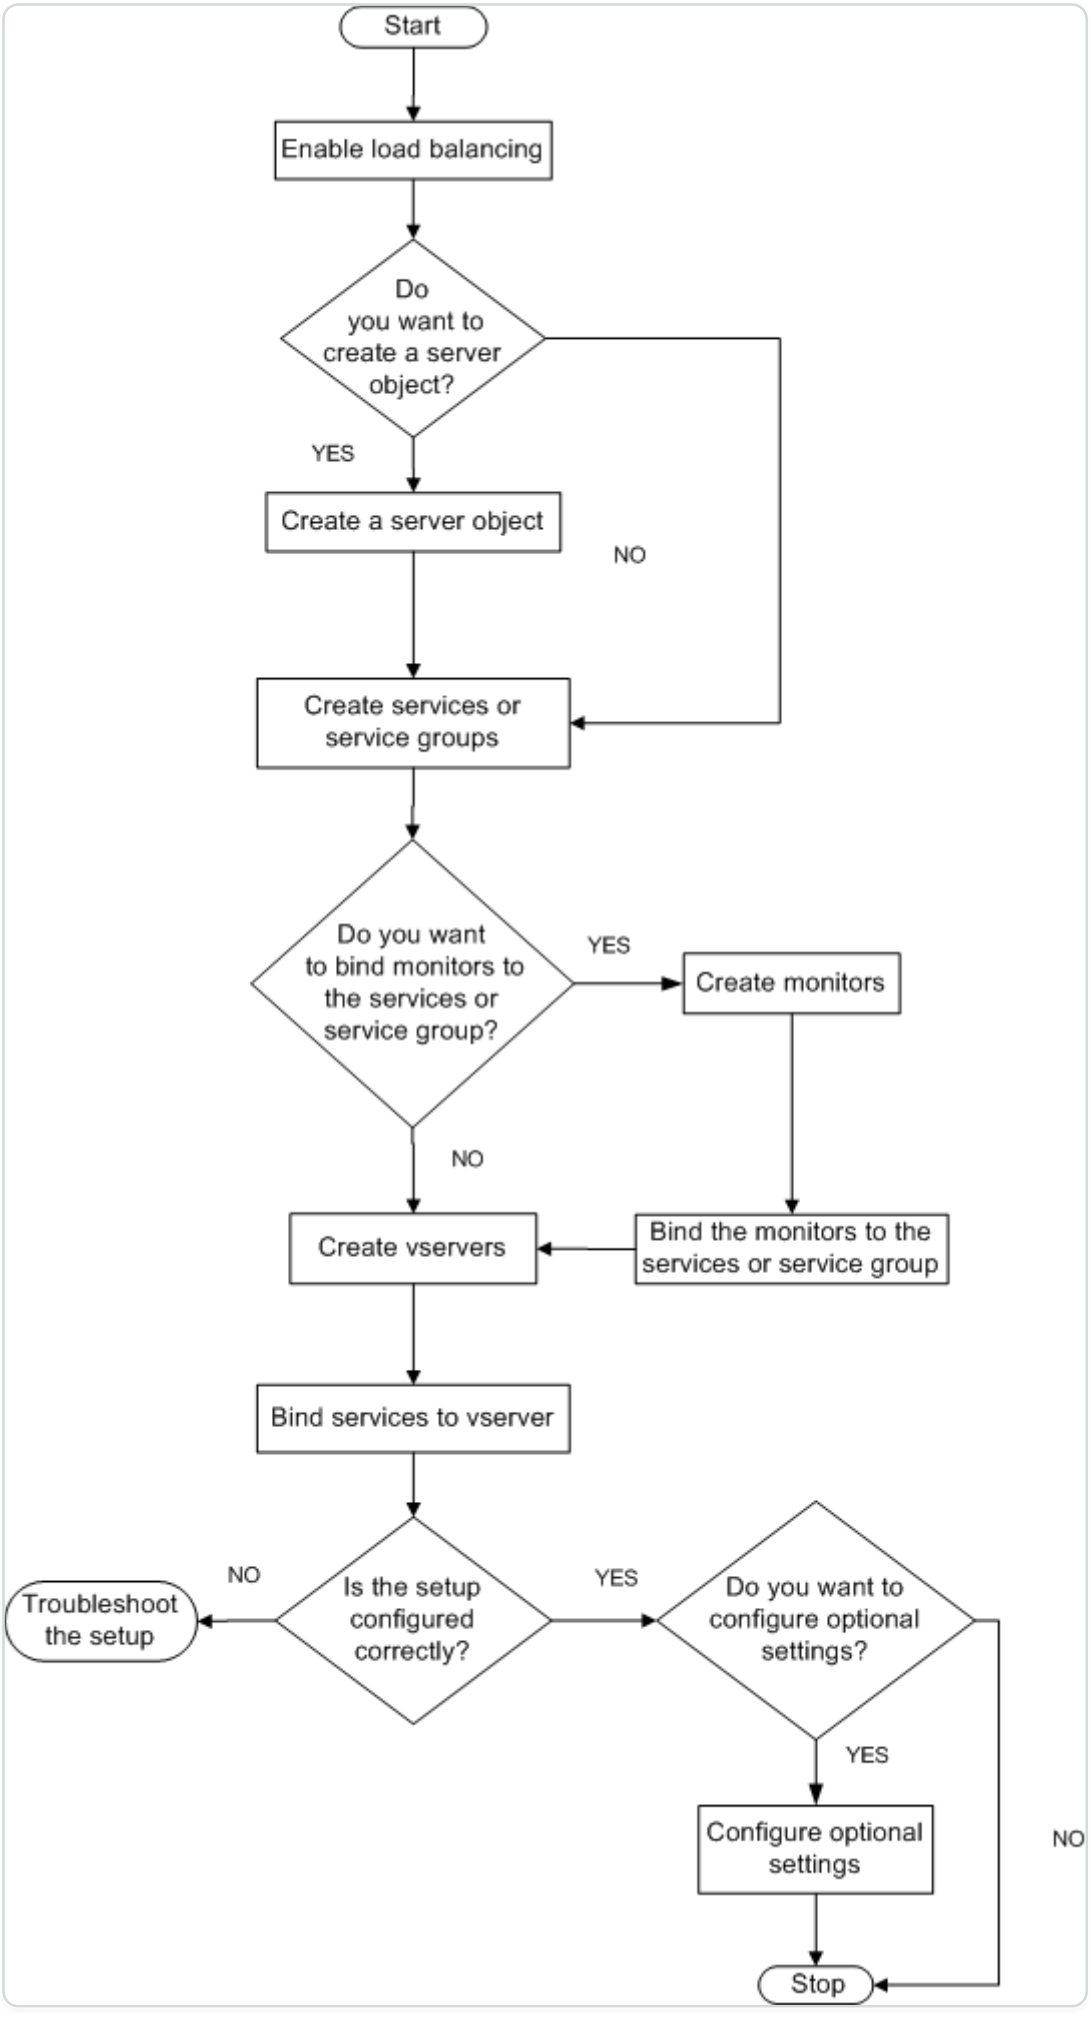
Note: After you deploy the configuration, you can display statistics that show how the entities in the configuration are performing. Use the statistical utility or the stat lb vserver \<vserverName\> command.

Optionally, you can assign weights to a service. The load balancing method then uses the assigned weight to select a service. For getting started, however, you can limit optional tasks to configuring some basic persistence settings, for sessions that must maintain a connection to a particular server, and some basic configuration-protection settings.

The following flow chart illustrates the sequence of the configuration tasks.

Figure 1. Sequence of Tasks to Configure Load Balancing

© 1997–2026 Citrix Systems, Inc. All rights reserved.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable load balancing

Before configuring load balancing, make sure that the load balancing feature is enabled.

To enable load balancing by using the CLI

At the command prompt, type the following commands to enable load balancing and verify that it is enabled:

- enable feature lb
- show feature

Example

```
> enable feature lb
 Done
> show feature

     Feature                 Acronym          Status
     -------                 -------          ------
 1)  Web Logging             WL               OFF
 2)  Surge Protection        SP               OFF
 3)  Load Balancing          LB               ON
 .
 .
 .
 9)  SSL Offloading          SSL              ON
 .
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
  .

  .

Done
```

To enable load balancing by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Load Balancing check box, and then click OK.
4. In the Enable/Disable Feature(s)? message, click Yes.

Configure services and a virtual server

When you have identified the services you want to load balance, you can implement your initial load balancing configuration by creating the service objects, creating a load balancing virtual server, and binding the service objects to the virtual server.

To implement the initial load balancing configuration by using the CLI

At the command prompt, type the following commands to implement and verify the initial configuration:

- <add service \<name\> \<IPaddress\> \<serviceType\> \<port\>
- <add lb vserver \<vServerName\> \<serviceType\> \[\<IPaddress\> \<port\>\]
- <bind lb vserver \<name\> \<serviceName\>
- <show service bindings \<serviceName\>

Example

```
> add service service-HTTP-1 10.102.29.5 HTTP 80

 Done

> add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
 Done
> bind lb vserver vserver-LB-1 service-HTTP-1
 Done
> show service bindings service-HTTP-1
   service-HTTP-1 (10.102.29.5:80) - State : DOWN

     1)      vserver-LB-1 (10.102.29.60:80) - State : DOWN
 Done
```

To implement the initial load balancing configuration by using the GUI

1. Navigate to Traffic Management > Load Balancing.
2. In the details pane, under Getting Started, click Load Balancing wizard, and follow the instructions to create a basic load balancing setup.
3. Return to the navigation pane, expand Load Balancing, and then click Virtual Servers.
4. Select the virtual server that you configured and verify that the parameters displayed at the bottom of the page are correctly configured.
5. Click Open.
6. Verify that each service is bound to the virtual server by confirming that the Active check box is selected for each service on the Services tab.

Persistence settings

You must configure persistence on a virtual server if you want to maintain the states of connections on the servers represented by that virtual server (for example, connections used in e-commerce). The appliance then uses the configured load balancing method for the initial selection of a server, but forwards to that same server all subsequent requests from the same client.

If persistence is configured, it overrides the load balancing methods once the server has been selected. If the configured persistence applies to a service that is down, the appliance uses the load balancing methods to select a new service, and the new service becomes persistent for

© 1997–2026 Citrix Systems, Inc. All rights reserved.

subsequent requests from the client. If the selected service is in an Out Of Service state, it continues to serve the outstanding requests but does not accept new requests or connections. After the shutdown period elapses, the existing connections are closed. The following table lists the types of persistence that you can configure.

PERSISTENCE TYPE	PERSISTENT CONNECTIONS
Source IP, SSL Session ID, Rule, DESTIP, SRCIPDESTIP	250K `*`
CookieInsert, URL passive, Custom Server ID	Memory limit. In case of CookieInsert, if time out is not 0, any number of connections is allowed until limited by memory.

The `*` in the preceding table refers to the following:

250K sessions per core is the default per packet engine. To configure 1 million session entries per packet engine, run the following command:

```
set lb parameter -sessionsthreshold <1000000*number of PE>
```

For a 3 PE system, run the following command:

```
set lb parameter -sessionsthreshold 3000000
```

Table 1. Limitations on Number of Simultaneous Persistent Connections

If the configured persistence cannot be maintained because of a lack of resources on an appliance, the load balancing methods are used for server selection. Persistence is maintained for a configured period of time, depending on the persistence type. Some persistence types are specific to certain virtual servers. The following table shows the relationship.

PERSISTENCE TYPEHEADER 1	HTTP	HTTPS	TCP	UDP/IP	SSL_BRIDGE
Source IP	YES	YES	YES	YES	YES
CookieInsert	YES	YES	NO	NO	NO
SSL Session ID	NO	YES	NO	NO	YES

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PERSISTENCE TYPEHEADER 1	HTTP	HTTPS	TCP	UDP/IP	SSL_BRIDGE
URL Passive	YES	YES	NO	NO	NO
Custom Server ID	YES	YES	NO	NO	NO
Rule	YES	YES	NO	NO	NO
SRCIPDESTIP	N/A	N/A	YES	YES	N/A
DESTIP	N/A	N/A	YES	YES	N/A

Table 2. Persistence Types Available for Each Type of Virtual Server

You can also specify persistence for a group of virtual servers. When you enable persistence on the group, the client requests are directed to the same selected server regardless of which virtual server in the group receives the client request. When the configured time for persistence elapses, any virtual server in the group can be selected for incoming client requests.

Two commonly used persistence types are persistence based on cookies and persistence based on server IDs in URLs.

Configure persistence based on cookies

When you enable persistence based on cookies, the NetScaler appliance adds an HTTP cookie into the **Set-Cookie header** field of the HTTP response. The cookie contains information about the service to which the HTTP requests must be sent. The client stores the cookie and includes it in all subsequent requests, and NetScaler uses it to select the service for those requests. You can use this type of persistence on virtual servers of type HTTP or HTTPS.

The NetScaler appliance inserts the cookie \<NSC_XXXX\>= \<ServiceIP\> \<ServicePort\> \<expires\>

where:

- <\<NSC_XXXX\> is the virtual server ID that is derived from the virtual server name.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- <\<ServiceIP\> is the hexadecimal value of the IP address of the service.
- <\<ServicePort\> is the hexadecimal value of the port of the service.
- <\<expires\> is the absolute expiration time for the cookie. The default value is 2 minutes

Once the specified date and time are reached, the client's browser automatically deletes the cookie from its cache. If the client's subsequent requests do not include the cookie value, the back-end server is selected based on the configured load balancing method.

If the `useEncryptedPersistenceCookie` option is enabled, NetScaler encrypts ServiceIP and ServicePort using the SHA2 hash algorithm when it inserts a cookie and decrypts when it receives a cookie.

Note: If the client is not allowed to store the HTTP cookie, the subsequent requests do not have the HTTP cookie, and persistence is not honored.

By default, NetScaler sends HTTP cookie version 0, in compliance with the Netscape specification. It can also send version 1, in compliance with RFC 2109.

You can configure a timeout value for persistence that is based on HTTP cookies. Note the following:

- If HTTP cookie version 0 is used, NetScaler inserts the absolute Coordinated Universal Time (UTC) of the cookie's expiration (the expires attribute of the HTTP cookie), calculated as the sum of the current UTC time on NetScaler, and the timeout value.
- If an HTTP cookie version 1 is used, NetScaler inserts a relative expiration time (Max-Age attribute of the HTTP cookie). In this case, the client software calculates the actual expiration time.

Note: Most client software currently installed (Microsoft Internet Explorer and Netscape browsers) understand HTTP cookie version 0; however, some HTTP proxies understand HTTP cookie version 1.

If you set the timeout value to 0, NetScaler does not specify the expiration time, regardless of the HTTP cookie version used. The expiration time then depends on the client software, and such cookies are not valid if that software is shut down. This persistence type does not consume any system resources. Therefore, it can accommodate an unlimited number of persistent clients.

An administrator can change the HTTP cookie version.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To change the HTTP cookie version by using the CLI

At the command prompt, type;

```
set ns param [-cookieversion ( 0 | 1 )]
```

Example:

```
set ns param -cookieversion 1
```

To change the HTTP cookie version by using the GUI

1. Navigate to **System > Settings**.
2. In the details pane, click Change HTTP Parameters.
3. In the Configure HTTP Parameters dialog box, under Cookie, select Version 0 or Version 1.

Note: For information about the parameters, see Configure persistence based on cookies.

To configure persistence based on cookies by using the CLI

At the command prompt, type the following commands to configure persistence based on cookies and verify the configuration:

```
set lb vserver <name> -persistenceType COOKIEINSERT

show lb vserver <name>
```

Example:

```
set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT

Done

show lb vserver vserver-LB-1

    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS

    .
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    .

    .

    Persistence: COOKIEINSERT (version 0)

    Persistence Timeout: 2 min

    .

    .

    .

Done
```

To configure persistence based on cookies by using the GUI

1. Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select COOKIEINSERT.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. Click OK.
6. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configure persistence based on server IDs in URLs

The NetScaler appliance can maintain persistence based on the server IDs in the URLs. In a technique called URL passive persistence, NetScaler extracts the server ID from the server response and embeds it in the URL query of the client request. The server ID is an IP address and the port specified as a hexadecimal number. NetScaler extracts the server ID from subsequent client requests and uses it to select the server.

URL passive persistence requires configuring either a payload expression or a policy infrastructure expression specifying the location of the server ID in the client requests. For more information about expressions, see Policy Configuration and Reference.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Note: If the server ID cannot be extracted from the client requests, server selection is based on the load balancing method.

Example: Payload Expression

The expression, URLQUERY contains sid= configures the system to extract the server ID from the URL query of a client request, after matching the token sid=. Thus, a request with the URL `http://www.citrix.com/index.asp?&sid;=c0a864100050` is directed to the server with the IP address 10.102.29.10 and port 80.

The timeout value does not affect this type of persistence, which is maintained as long as the server ID can be extracted from the client requests. This persistence type does not consume any system resources, so it can accommodate an unlimited number of persistent clients.

Note: For information about the parameters, see Load Balancing.

To configure persistence based on server IDs in URLs by using the CLI

At the command prompt, type the following commands to configure persistence based on server IDs in URLs and verify the configuration:

```
set lb vserver <name> -persistenceType URLPASSIVE

<show lb vserver <name>
```

Example:

```
set lb vserver vserver-LB-1 -persistenceType URLPASSIVE

Done

show lb vserver vserver-LB-1

    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS

    .

    .
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    .

    Persistence: URLPASSIVE

    Persistence Timeout: 2 min

    .

    .

    .

Done
```

To configure persistence based on server IDs in URLs by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure persistence (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Method and Persistence tab, in the Persistence list, select URLPASSIVE.
4. In the Time-out (min) text box, type the time-out value (for example, 2).
5. In the Rule text box, enter a valid expression. Alternatively, click Configure next to the Rule text box and use the Create Expression dialog box to create an expression.
6. Click OK.
7. Verify that the virtual server for which you configured persistence is correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane.

Configure features to protect the load balancing configuration

You can configure URL redirection to provide notifications of virtual server malfunctions, and you can configure backup virtual servers to take over if a primary virtual server becomes unavailable.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure URL redirection

You can configure a redirect URL to communicate the status of the appliance in the event that a virtual server of type HTTP or HTTPS is down or disabled. This URL can be a local or remote link. The appliance uses HTTP 302 redirect.

Redirects can be absolute URLs or relative URLs. If the configured redirect URL contains an absolute URL, the HTTP redirect is sent to the configured location, regardless of the URL specified in the incoming HTTP request. If the configured redirect URL contains only the domain name (relative URL), the HTTP redirect is sent to a location after appending the incoming URL to the domain configured in the redirect URL.

Note: If a load balancing virtual server is configured with both a backup virtual server and a redirect URL, the backup virtual server takes precedence over the redirect URL. In this case, a redirect is used when both the primary and backup virtual servers are down.

To configure a virtual server to redirect client requests to a URL by using the CLI

At the command prompt, type the following commands to configure a virtual server to redirect client requests to a URL and verify the configuration:

```
set lb vserver <name> -redirectURL <URL>

show lb vserver <name>
```

Example:

```
> set lb vserver vserver-LB-1 -redirectURL <http://www.newdomain.com/
mysite/maintenance>

 Done

> show lb vserver vserver-LB-1

    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS

    State: DOWN

    Last state change was at Wed Jun 17 08:56:34 2009 (+666 ms)
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    .

    .

    .

    Redirect URL: <http://www.newdomain.com/mysite/maintenance>

    .

    .

    .

 Done

>
```

To configure a virtual server to redirect client requests to a URL by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure URL redirection (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Redirect URL text box, type the URL (for example, `http://www.newdomain.com/mysite/maintenance`), and then click OK.
4. Verify that the redirect URL you configured for the server appears in the Details section at the bottom of the pane.

Configure backup virtual servers

If the primary virtual server is down or disabled, the appliance can direct the connections or client requests to a backup virtual server that forwards the client traffic to the services. The appliance can also send a notification message to the client regarding the site outage or maintenance. The backup virtual server is a proxy and is transparent to the client.

You can configure a backup virtual server when you create a virtual server or when you change the optional parameters of an existing virtual server. You can also configure a backup virtual server for

© 1997–2026 Citrix Systems, Inc. All rights reserved.

an existing backup virtual server, thus creating a cascaded backup virtual server. The maximum depth of cascading backup virtual servers is 10. The appliance searches for a backup virtual server that is up and accesses that virtual server to deliver the content.

You can configure URL redirection on the primary for use when the primary and the backup virtual servers are down or have reached their thresholds for handling requests.

Note: If no backup virtual server exists, an error message appears, unless the virtual server is configured with a redirect URL. If both a backup virtual server and a redirect URL are configured, the backup virtual server takes precedence.

To configure a backup virtual server by using the CLI

At the command prompt, type the following commands to configure a backup server and verify the configuration:

```
set lb vserver <name> [-backupVserver <string>]

show lb vserver <name>
```

Example:

```
> set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

 Done

> show lb vserver vserver-LB-1

    vserver-LB-1 (10.102.29.60:80) - HTTP   Type: ADDRESS

    State: DOWN

    Last state change was at Wed Jun 17 08:56:34 2009 (+661 ms)

    .

    .

    .
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    Backup: vserver-LB-2

    .

    .

    .

 Done

>
```

To set up a backup virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server for which you want to configure the backup virtual server (for example, vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Advanced tab, in the Backup Virtual Server list, select the backup virtual server (for example, vserver-LB-2, and then click OK.
4. Verify that the backup virtual server you configured appears in the Details section at the bottom of the pane.

   Note: If the primary server goes down and then comes back up, and you want the backup virtual server to function as the primary server until you explicitly reestablish the primary virtual server, select the Disable Primary When Down check box.

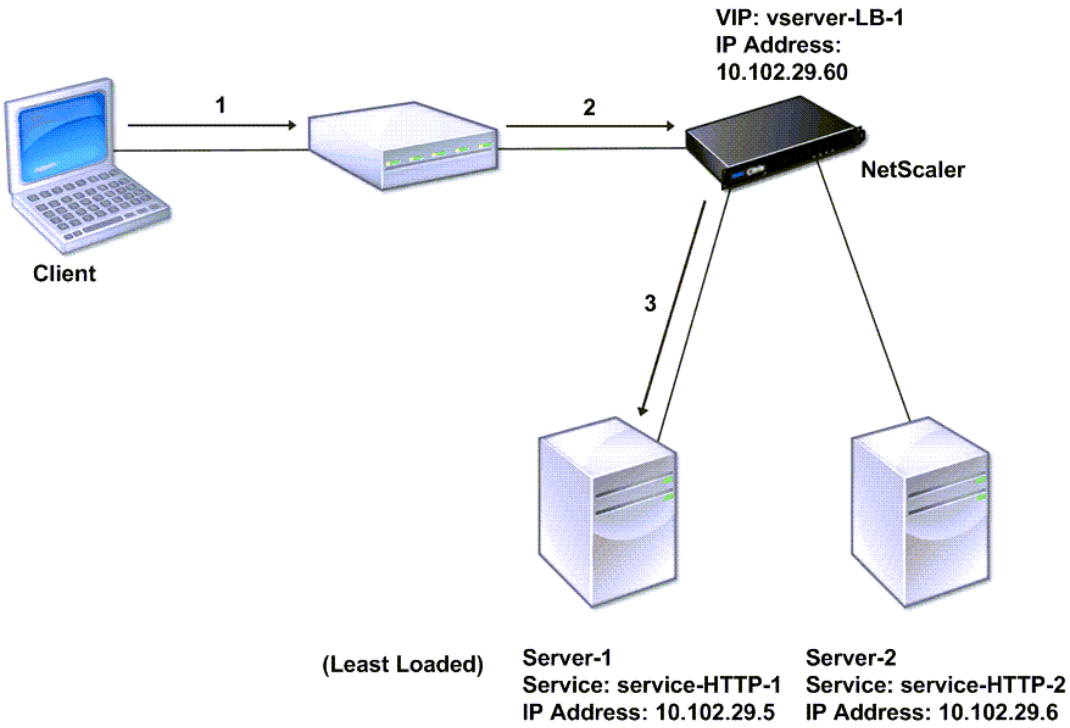
A typical load balancing scenario

In a load balancing setup, the NetScaler appliances are logically located between the client and the server farm, and they manage traffic flow to the servers.

The following figure shows the topology of a basic load balancing configuration.

Figure 1. Basic Load Balancing Topology

© 1997–2026 Citrix Systems, Inc. All rights reserved.



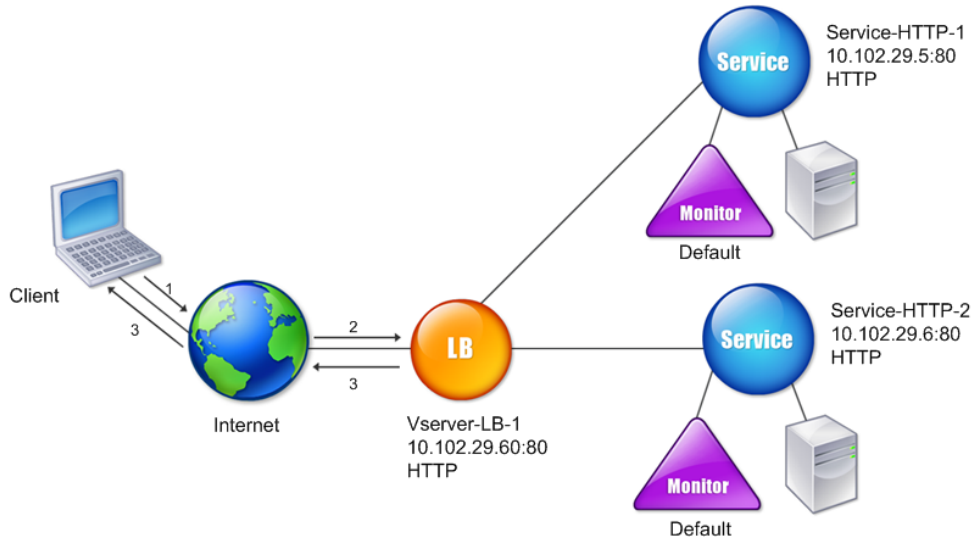
The virtual server selects the service and assigns it to serve client requests. Consider the scenario in the preceding figure, where the services service-HTTP-1 and service-HTTP-2 are created and bound to the virtual server named virtual server-LB-1. Virtual server-LB-1 forwards the client request to either service-HTTP-1 or service-HTTP-2. The system selects the service for each request by using the Least Connections load balancing method. The following table lists the names and values of the basic entities that must be configured on the system.

Table 1. LB Configuration Parameter Values

The following figure shows the load balancing sample values and required parameters that are described in the preceding table.

Figure 2. Load Balancing Entity Model

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The following tables list the commands used to configure this load balancing setup by using the command line interface.

TASK	COMMAND
To enable load balancing	enable feature lb
To create a service named service-HTTP-1	add service service-HTTP-1 10.102.29.5 HTTP 80
To create a service named service-HTTP-2	add service service-HTTP-2 10.102.29.6 HTTP 80
To create a virtual server named vserver-LB-1	add lb vserver vserver-LB-1 HTTP 10.102.29.60 80
To bind a service named service-HTTP-1 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-1
To bind a service named service-HTTP-2 to a virtual server named vserver-LB-1	bind lb vserver vserver-LB-1 service-HTTP-2

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Table 2. Initial Configuration Tasks

For more information about the initial configuration tasks, see Setting Up Basic Load Balancing.

TASK	COMMAND
To view the properties of a virtual server named vserver-LB-1	show lb vserver vserver-LB-1
To view the statistics of a virtual server named vserver-LB-1	stat lb vserver vserver-LB-1
To view the properties of a service named service-HTTP-1	show service service-HTTP-1
To view the statistics of a service named service-HTTP-1	stat service service-HTTP-1
To view the bindings of a service named service-HTTP-1	show service bindings service-HTTP-1

Table 3. Verification Tasks

TASK	COMMAND
To configure persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType SOURCEIP -persistenceMask 255.255.255.255 -timeout 2
To configure COOKIEINSERT persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType COOKIEINSERT
To configure URLPassive persistence on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -persistenceType URLPASSIVE
To configure a virtual server to redirect the client request to a URL on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -redirectURL `http://www.newdomain.com/mysite/maintenance`
To set a backup virtual server on a virtual server named vserver-LB-1	set lb vserver vserver-LB-1 -backupVserver vserver-LB-2

Table 4. Customization Tasks

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For more information about configuring persistence, see Choosing and Configuring Persistence Settings. For information about configuring a virtual server to redirect a client request to a URL and setting up a backup virtual server, see Configuring Features to Protect the Load Balancing Configuration.

Use case: How to force Secure and HttpOnly cookie options for websites using the NetScaler appliance

The web administrators may force the Secure, or HttpOnly, or both the flags on the Session ID and the authentication cookies that are generated by the web applications. You can modify the Set-cookie headers to include these two options by using an HTTP load balancing virtual server and rewrite policies on a NetScaler appliance.

- **HttpOnly** - This option on a cookie causes the web browsers to return the cookie using the HTTP or HTTPS protocol only. The non-HTTP methods such as JavaScript document.cookie references cannot access the cookie. This option helps in preventing cookie theft due to cross-site scripting.

  NOTE

  > You cannot use the HttpOnly option when a web application requires access to Cookie contents by using a client-side script, such as JavaScript or a client-side Java Applet. You can use the method mentioned in this document to rewrite only the server-generated cookies and not the cookies generated by NetScaler appliance. For example, AppFirewall, persistence, VPN session cookies and so on.

- **Secure** - This option on a cookie causes the web browsers to return only the cookie value when the transmission is encrypted by SSL. This option can be used to prevent cookie theft through connection eavesdropping.

NOTE

> The following procedure is not applicable for VPN virtual servers.

To configure the NetScaler appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using CLI

1. Create a rewrite action.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This example is configured to set both Secure and HttpOnly flags. If either one is missing, modify it as necessary for other combinations.

```
add rewrite action act_cookie_Secure replace_all http.RES.full_Header
"\"Secure; HttpOnly; path=/\"" -search "regex(re!(path=/\\; Secure;
HttpOnly)|(path=/\\; Secure)|(path=/\\; HttpOnly)|(path=/)!)"
```

This policy replaces all instances of "path=/", "path=/; Secure", "path=/; Secure; HttpOnly" and "path=/; HttpOnly" with "Secure; HttpOnly; path=/". This regular expression (regex) fails if the case doesn't match.

2. Create a rewrite policy to trigger the action.

```
add rewrite policy rw_force_secure_cookie "http.RES.HEADER(\"Set-
Cookie\").EXISTS" act_cookie_Secure
```

3. Bind the rewrite policy to the virtual server to be secured. If `Secure` option is used, an SSL virtual server must be used.

```
bind lb vserver mySSLVServer -policyName rw_force_secure_cookie
-priority 100 -gotoPriorityExpression NEXT -type RESPONSE
```

Examples:

The following example shows the cookie before setting the httpOnly flag

```
Set-Cookie: CtxsAuthId=C5614491; path=/Citrix/ProdWeb
```

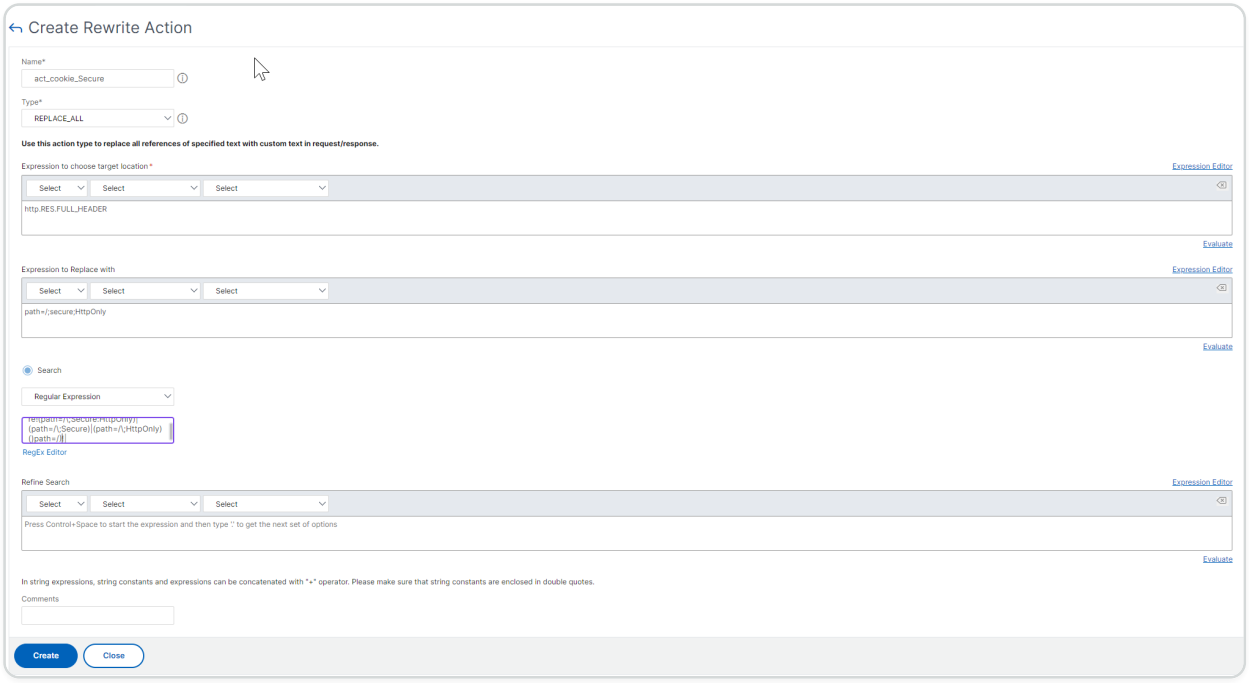
The following example shows the cookie after setting the httpOnly flag

```
Set-Cookie: CtxsAuthId=C5614491; Secure; HttpOnly; path=/Citrix/ProdWeb/
```

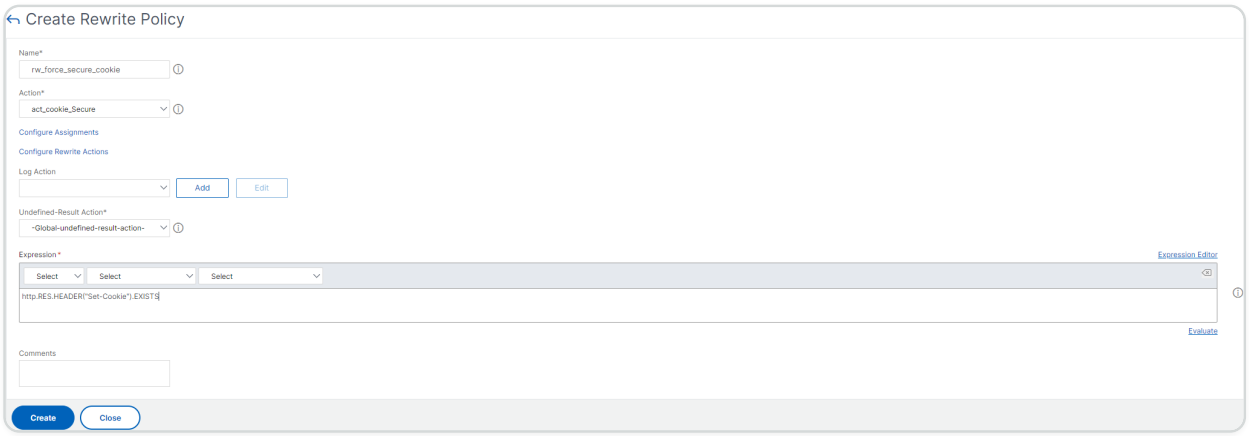
To configure the NetScaler appliance to force the Secure and HttpOnly flags for an existing HTTP virtual server by using GUI

1. Navigate to **AppExpert > Rewrite > Actions**, and click **Add** to add a new rewrite action.

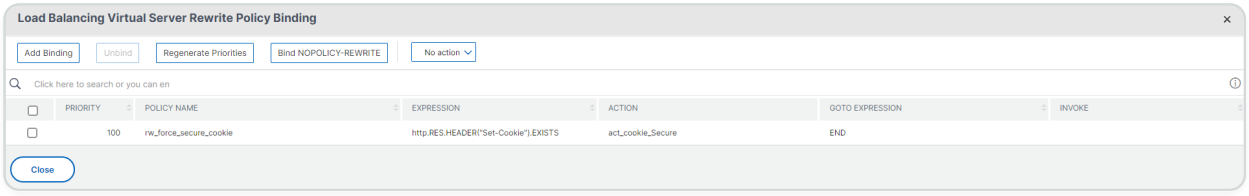
© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. Navigate to **AppExpert > Rewrite > Policies**, and click **Add** to add a new rewrite policy.



3. Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and then bind the rewrite (response) policy to the corresponding SSL virtual server.



Accelerate load balanced traffic by using compression

Compression is a popular means of optimizing bandwidth usage, and most web browsers support compressed data. If you enable the compression feature, the NetScaler appliance intercepts requests from clients and determines whether the client can accept compressed content. After receiving the HTTP response from the server, the appliance examines the content to determine whether it is compressible. If the content is compressible, the appliance compresses it, modifies

© 1997–2026 Citrix Systems, Inc. All rights reserved.

the response header to indicate the type of compression performed, and forwards the compressed content to the client.

NetScaler compression is a policy-based feature. A policy filters requests and responses to identify responses to be compressed, and specifies the type of compression to apply to each response. The appliance provides several built-in policies to compress common MIME types such as text/html, text/plain, text/xml, text/css, text/rtf, application/msword, application/vnd.ms-excel, and application/vnd.ms-powerpoint. You can also create custom policies. The appliance does not compress compressed MIME types such as application/octet-stream, binary, bytes, and compressed image formats such as GIF and JPEG.

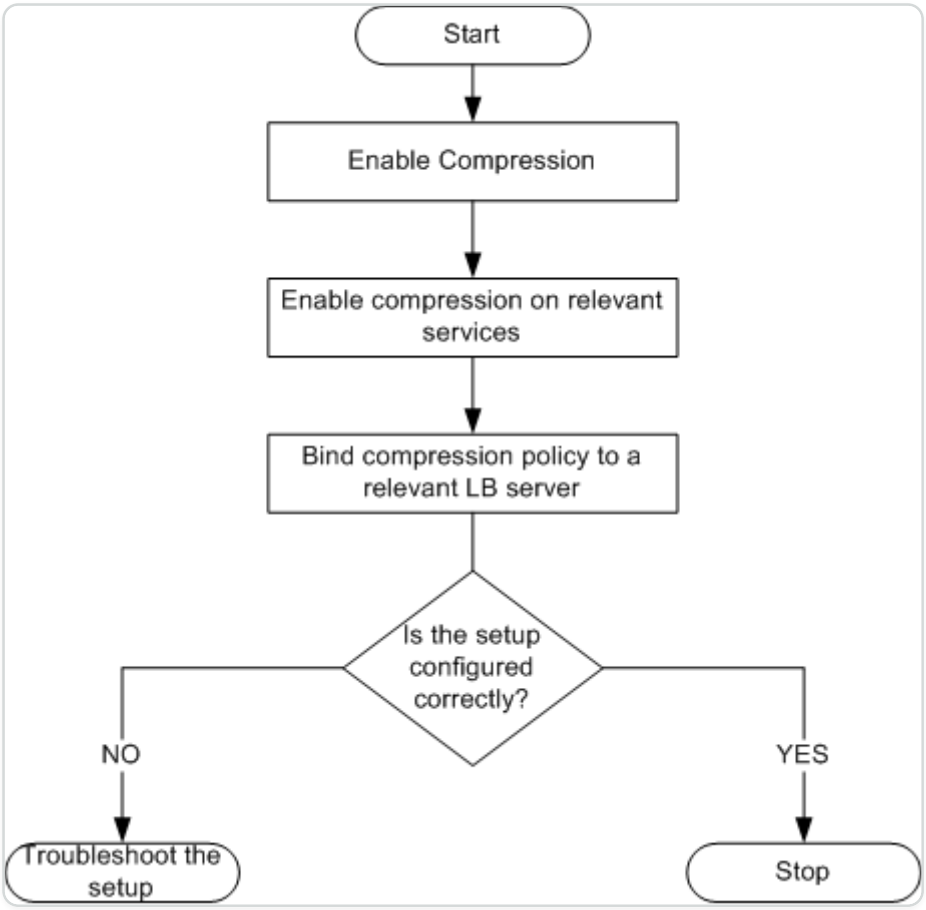
To configure compression, you must enable it globally and on each service that will provide responses that you want compressed. If you have configured virtual servers for load balancing or content switching, you should bind the polices to the virtual servers. Otherwise, the policies apply to all traffic that passes through the appliance.

Compression configuration task sequence

The following flow chart shows the sequence of tasks for configuring basic compression in a load balancing setup.

Figure 1. Sequence of Tasks to Configure Compression

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Note: The steps in the above figure assume that load balancing has already been configured.

Enable compression

By default, compression is not enabled. You must enable the compression feature to allow compression of HTTP responses that are sent to the client.

To enable compression by using the CLI

At the command prompt, type the following commands to enable compression and verify the configuration:

- enable ns feature CMP
- show ns feature

```
> enable ns feature CMP
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

> show ns feature

        Feature                         Acronym             Status

        -------                         -------             ------

1)      Web Logging                     WL                  ON

2)      Surge Protection                SP                  OFF
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    .

    7) Compression Control CMP ON

       .

    Done
```

To enable compression by using the GUI

1. In the navigation pane, expand System, and then click Settings.
2. In the details pane, under Modes and Features, click Change basic features.
3. In the Configure Basic Features dialog box, select the Compression check box, and then click OK.
4. In the Enable/Disable Feature(s)? dialog box, click Yes.

Configure services to compress data

In addition to enabling compression globally, you must enable it on each service that will deliver files to be compressed.

To enable compression on a service by using the CLI

At the command prompt, type the following commands to enable compression on a service and verify the configuration:

- set service \<name\> -CMP YES

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- show service \<name\>

```
> show service SVC_HTTP1

SVC_HTTP1 (10.102.29.18:80) - HTTP

State: UP

Last state change was at Tue Jun 16 06:19:14 2009 (+737 ms)

Time since last state change: 0 days, 03:03:37.200

Server Name: 10.102.29.18

Server ID : 0   Monitor Threshold : 0
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits

Use Source IP: NO

Client Keepalive(CKA): NO

Access Down Service: NO

TCP Buffering(TCPB): NO

HTTP Compression(CMP): YES

Idle timeout: Client: 180 sec   Server: 360 sec
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Client IP: DISABLED

Cacheable: NO

SC: OFF

SP: OFF

Down state flush: ENABLED

1)      Monitor Name: tcp-default

State: DOWN     Weight: 1

```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Last response: Failure - TCP syn sent, reset received.

Response Time: N/A

Done
```

To enable compression on a service by using the GUI

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service for which you want to configure compression (for example, service-HTTP-1), and then click Open.
3. On the Advanced tab, under Settings, select the Compression check box, and then click OK.
4. Verify that, when the service is selected, HTTP Compression(CMP): ON appears in the **Details** section at the bottom of the pane.

Bind a compression policy to a virtual server

If you bind a policy to a virtual server, the policy is evaluated only by the services associated with that virtual server. You can bind compression policies to a virtual server either from the Configure Virtual Server (Load Balancing) dialog box or from the Compression Policy Manager dialog box. This topic includes instructions to bind compression policies to a load balancing virtual server by using the Configure Virtual Server (Load Balancing) dialog box.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind or unbind a compression policy to a virtual server by using the command line

At the command prompt, type the following commands to bind or unbind a compression policy to a load balancing virtual server and verify the configuration:

```
bind lb vserver <name> -policyName <string>

Done

unbind lb vserver <name> -policyName <string>

Done

show lb vserver <name>
```

Example:

```

> bind lb vserver lbvip -policyName ns_cmp_msapp

Done

> show lb vserver lbvip

lbvip (8.7.6.6:80)-HTTPType:ADDRESS

To bind or unbind a compression policy to a load balancing virtual server by using the GUI

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind or unbind a compression policy (for example, Vserver-LB-1), and then click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, on the Policies tab, click Compression.
4. Do one of the following:
   - To bind a compression policy, click Insert Policy, and then select the policy you want to bind to the virtual server.
   - To unbind a compression policy, click the name of the policy you want to unbind from the virtual server, and then click Unbind Policy.
5. Click OK.

Secure load balanced traffic by using SSL

The NetScaler SSL offload feature transparently improves the performance of websites that conduct SSL transactions. By offloading CPU-intensive SSL encryption and decryption tasks from the local web server to the appliance, SSL offloading ensures secure delivery of web applications without the performance penalty incurred when the server processes the SSL data. Once the SSL traffic is decrypted, it can be processed by all standard services. The SSL protocol works seamlessly with various types of HTTP and TCP data and provides a secure channel for transactions using such data.

To configure SSL, you must first enable it. Then, you configure HTTP or TCP services and an SSL virtual server on the appliance, and bind the services to the virtual server. You must also add a certificate-key pair and bind it to the SSL virtual server. If you use Outlook Web Access servers, you must create an action to enable SSL support and a policy to apply the action. An SSL virtual server intercepts incoming encrypted traffic and decrypts it by using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the appliance for appropriate processing.

For detailed information about SSL offloading, see SSL offload and acceleration.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SSL configuration task sequence

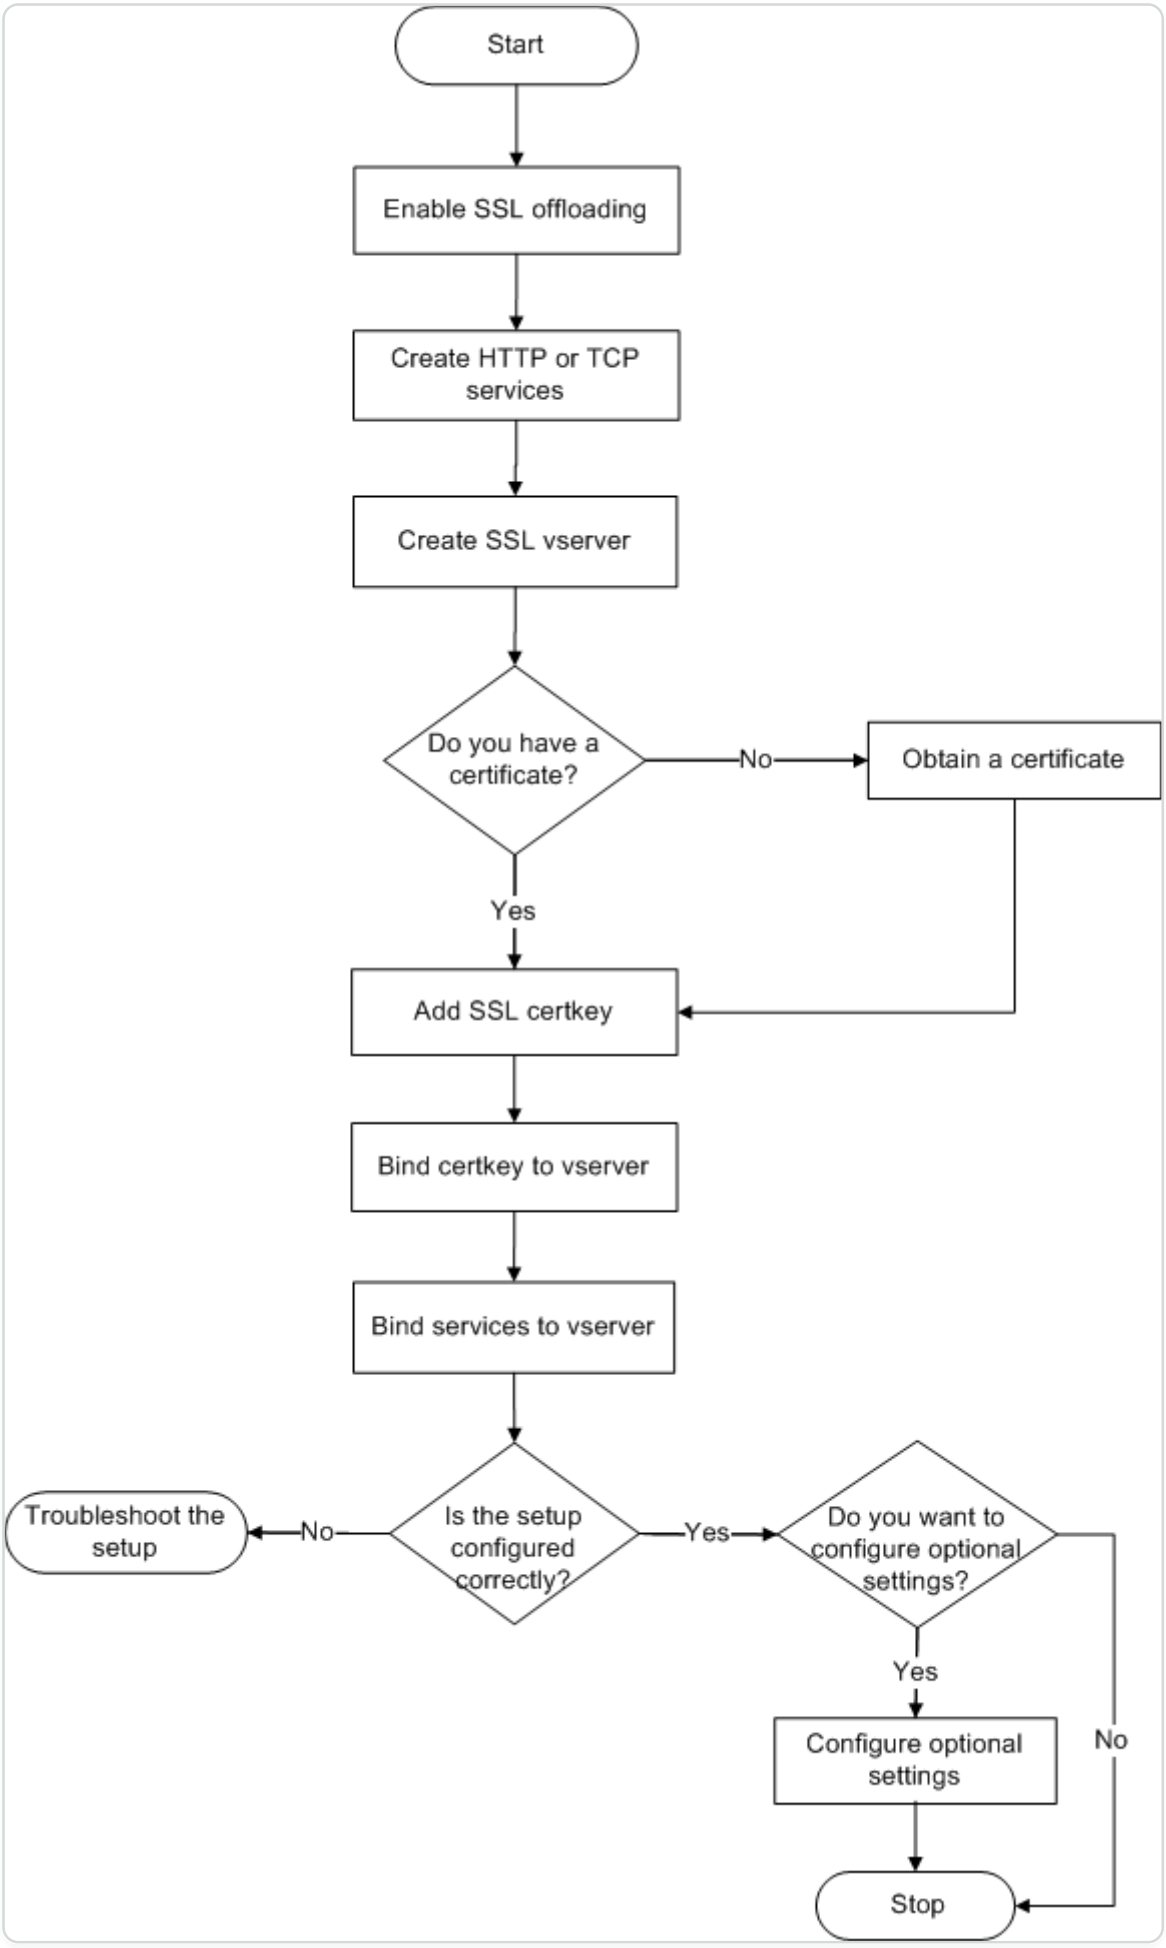
To configure SSL, you must first enable it. Then, you must create an SSL virtual server and HTTP or TCP services on the NetScaler appliance. Finally, you must bind a valid SSL certificate and the configured services to the SSL virtual server.

An SSL virtual server intercepts incoming encrypted traffic and decrypts it using a negotiated algorithm. The SSL virtual server then forwards the decrypted data to the other entities on the NetScaler appliance for appropriate processing.

The following flow chart shows the sequence of tasks for configuring a basic SSL offload setup.

Figure 1. Sequence of Tasks to Configure SSL Offloading

© 1997–2026 Citrix Systems, Inc. All rights reserved.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enable SSL offload

First enable the SSL feature. You can configure SSL-based entities on the appliance without enabling the SSL feature, but they will not work until you enable SSL.

Enable SSL by using the CLI

At the command prompt, type the following commands to enable SSL Offload and verify the configuration:

```
-  enable ns feature SSL

-  show ns feature
```

Example:

```
> enable ns feature ssl

Done

> show ns feature

Feature Acronym Status

------- ------- ------

```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
1) Web Logging WL ON

2) SurgeProtection SP OFF

3) Load Balancing LB ON . . .

 9) SSL Offloading SSL ON

10) Global Server Load Balancing GSLB ON . .

Done >
```

Enable SSL by using the GUI

Follow these steps:

1. In the navigation pane, expand **System**, and then click **Settings**.
2. In the details pane, under **Modes and Features**, click **Change basic features**.
3. Select the **SSL Offloading** check box, and then click **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. In the **Enable/Disable Feature(s)?** message box, click **Yes**.

Create HTTP services

A service on the appliance represents an application on a server. Once configured, services are in the disabled state until the appliance can reach the server on the network and monitor its status. This topic covers the steps to create an HTTP service.

Note: For TCP traffic, perform the following procedures, but create TCP services instead of HTTP services.

Add an HTTP service by using the CLI

At the command prompt, type the following commands to add an HTTP service and verify the configuration:

```
-  add service <name> (<IP> | <serverName>) <serviceType> <port>

-  show service <name>
```

Example:

```
> add service SVC_HTTP1 10.102.29.18 HTTP 80

 Done

> show service SVC_HTTP1

        SVC_HTTP1 (10.102.29.18:80) - HTTP
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
State: UP

Last state change was at Wed Jul 15 06:13:05 2009

Time since last state change: 0 days, 00:00:15.350

Server Name: 10.102.29.18

Server ID : 0   Monitor Threshold : 0

Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits

Use Source IP: NO
```

```
        Client Keepalive(CKA): NO

        Access Down Service: NO

        TCP Buffering(TCPB): NO

        HTTP Compression(CMP): YES

        Idle timeout: Client: 180 sec   Server: 360 sec

        Client IP: DISABLED

        Cacheable: NO
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        SC: OFF

        SP: OFF

        Down state flush: ENABLED

1)      Monitor Name: tcp-default

                State: UP       Weight: 1

                Probes: 4       Failed [Total: 0 Current: 0]

                Last response: Success - TCP syn+ack received.
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                Response Time: N/A

 Done
```

Add an HTTP service by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Services**.
2. In the details pane, click **Add**.
3. In the **Create Service** dialog box, type the name of the service, IP address, and port (for example, SVC_HTTP1, 10.102.29.18, and 80).
4. In the **Protocol** list, select the type of the service (for example, HTTP).
5. Click **Create**, and then click **Close**. The HTTP service you configured appears in the Services page.
6. Verify that the parameters you configured are correctly configured by selecting the service and viewing the Details section at the bottom of the pane.

Add an SSL based virtual server

In a basic SSL offloading setup, the SSL virtual server intercepts encrypted traffic, decrypts it, and sends the clear text messages to the services that are bound to the virtual server. Offloading CPU-intensive SSL processing to the appliance allows the back-end servers to process a greater number of requests.

Add an SSL-based virtual server by using the CLI

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-  add lb vserver <name> <serviceType> [<IPAddress> <port>]

-  show lb vserver <name>
```

CAUTION:

To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Example:

```
> add lb vserver vserver-SSL-1 SSL 10.102.29.50 443

  Done

  > show lb vserver vserver-SSL-1

  vserver-SSL-1 (10.102.29.50:443) - SSL Type: ADDRESS

  State: DOWN[Certkey not bound] Last state change was at Tue Jun 16
06:33:08 2009 (+176 ms)

  Time since last state change: 0 days, 00:03:44.120
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Effective State: DOWN Client Idle Timeout: 180 sec

Down state flush: ENABLED

Disable Primary Vserver On Down : DISABLED

No. of Bound Services : 0 (Total) 0 (Active)

Configured Method: LEASTCONNECTION Mode: IP

Persistence: NONE

Vserver IP and Port insertion: OFF
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
  Push: DISABLED Push VServer: Push Multi Clients: NO Push Label Rule:
Done
```

Add an SSL-based virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, click **Add**.
3. In the **Create Virtual Server (SSL Offload)** dialog box, type the name of the virtual server, IP address, and port.
4. In the **Protocol** list, select the type of the virtual server, for example, SSL.
5. Click **Create**, and then click **Close**.
6. Verify that the parameters you configured are correctly configured by selecting the virtual server and viewing the Details section at the bottom of the pane. The virtual server is marked as DOWN because a certificate-key pair and services have not been bound to it.

CAUTION:

To ensure secure connections, you must bind a valid SSL certificate to the SSL-based virtual server before you enable it.

Bind services to the SSL virtual server

After decrypting the incoming data, the SSL virtual server forwards the data to the services that you have bound to the virtual server.

Data transfer between the appliance and the servers can be encrypted or in clear text. If the data transfer between the appliance and the servers is encrypted, the entire transaction is secure from end to end. For more information about configuring the system for end-to-end security, see SSL offload and acceleration.

Bind a service to a virtual server by using the CLI

At the command prompt, type the following commands to bind a service to the SSL virtual server and verify the configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-  bind lb vserver <name> <serviceName>

-  show lb vserver <name>
```

Example:

```
> bind lb vserver vserver-SSL-1 SVC_HTTP1

  Done

  > show lb vserver vserver-SSL-1 vserver-SSL-1 (10.102.29.50:443) - SSL
Type:

  ADDRESS State: DOWN[Certkey not bound]

  Last state change was at Tue Jun 16 06:33:08 2009 (+174 ms)

  Time since last state change: 0 days, 00:31:53.70
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
  Effective State: DOWN Client Idle

  Timeout: 180 sec

  Down state flush: ENABLED Disable Primary Vserver On Down :

  DISABLED No. of Bound Services : 1 (Total) 0 (Active)

  Configured Method: LEASTCONNECTION Mode: IP Persistence: NONE Vserver IP
and

  Port insertion: OFF Push: DISABLED Push VServer: Push Multi Clients: NO
Push Label Rule:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
1) SVC_HTTP1 (10.102.29.18: 80) - HTTP

State: DOWN Weight: 1

Done
```

Bind a service to a virtual server by using the GUI

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, select a virtual server, and then click **Open**.
3. On the **Services** tab, in the **Active** column, select the check boxes next to the services that you want to bind to the selected virtual server.
4. Click **OK**.
5. Verify that the Number of Bound Services counter in the Details section at the bottom of the pane is incremented by the number of services that you bound to the virtual server.

Add a certificate-key pair

An SSL certificate is an integral element of the SSL Key-Exchange and encryption/decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server. You can use a valid, existing SSL certificate that you have on the NetScaler appliance, or you can create your own SSL certificate. The appliance supports RSA certificates of up to 4096 bits.

ECDSA certificates with only the following curves are supported:

- prime256v1 (P_256 on the ADC)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- secp384r1 (P_384 on the ADC)
- secp521r1 (P_521 on the ADC; supported on VPX only)
- secp224r1 (P_224 on the ADC; supported on VPX only)

NOTE:

Citrix® recommends that you use a valid SSL certificate that has been issued by a trusted certificate authority. Invalid certificates and self-created certificates are not compatible with all SSL clients.

Before a certificate can be used for SSL processing, you must pair it with its corresponding key. The certificate key pair is then bound to the virtual server and used for SSL processing.

Add a certificate key pair by using the CLI

Note: For information about creating an ECDSA certificate-key pair, see Create an ECDSA certificate-key pair.

At the command prompt, type the following commands to create a certificate key pair and verify the configuration:

```
-  add ssl certKey <certkeyName> -cert <string> [-key <string>]

-  show sslcertkey <name>
```

Example:

```
> add ssl certKey CertKey-SSL-1 -cert ns-root.cert -key ns-root.key

 Done

> show sslcertkey CertKey-SSL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
   Name: CertKey-SSL-1 Status: Valid,

   Days to expiration:4811 Version: 3

   Serial Number: 00 Signature Algorithm: md5WithRSAEncryption Issuer:
C=US,ST=California,L=San

   Jose,O=Citrix ANG,OU=NS Internal,CN=de fault

   Validity Not Before: Oct 6 06:52:07 2006 GMT Not After : Aug 17

efault Public Key

   Algorithm: rsaEncryption Public Key
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    size: 1024

  Done
```

Add a certificate key pair by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Certificates**.
2. In the details pane, click **Add**.
3. In the **Install Certificate** dialog box, in the Certificate-Key Pair Name text box, type a name for the certificate key pair you want to add, for example, Certkey-SSL-1.
4. Under **Details**, in Certificate File Name, click **Browse (Appliance)** to locate the certificate. Both the certificate and the key are stored in the /nsconfig/ssl/ folder on the appliance. To use a certificate present on the local system, select Local.
5. Select the certificate you want to use, and then click **Select**.
6. In Private Key File Name, click **Browse (Appliance)** to locate the private key file. To use a private key present on the local system, select Local.
7. Select the key you want to use and click **Select**. To encrypt the key used in the certificate key pair, type the password to be used for encryption in the Password text box.
8. Click **Install**.
9. Double-click the certificate key pair and, in the Certificate Details window, verify that the parameters have been configured correctly and saved.

Bind an SSL certificate key pair to the virtual server

After you pairing an SSL certificate with its corresponding key, bind the certificate-key pair to the SSL virtual server so that it can be used for SSL processing. Secure sessions require establishing a connection between the client computer and an SSL-based virtual server on the appliance. SSL processing is then carried out on the incoming traffic at the virtual server. Therefore, before

© 1997–2026 Citrix Systems, Inc. All rights reserved.

enabling the SSL virtual server on the appliance, you need to bind a valid SSL certificate to the SSL virtual server.

Bind an SSL certificate key pair to a virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL certificate key pair to a virtual server and verify the configuration:

```
-  bind ssl vserver <vServerName> -certkeyName <string>

-  show ssl vserver <name>
```

Example:

```
> bind ssl vserver Vserver-SSL-1 -certkeyName CertKey-SSL-1

Done

> show ssl vserver Vserver-SSL-1

     Advanced SSL configuration for VServer Vserver-SSL-1:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    DH: DISABLED

    Ephemeral RSA: ENABLED Refresh Count: 0

    Session Reuse: ENABLED Timeout: 120 seconds

    Cipher Redirect: ENABLED

    SSLv2 Redirect: ENABLED

    ClearText Port: 0

    Client Auth: DISABLED
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
     SSL Redirect: DISABLED

     Non FIPS Ciphers: DISABLED

     SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Cipher Name: DEFAULT

   Description: Predefined Cipher Alias
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Bind an SSL certificate key pair to a virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. Select the virtual server to which you want to bind the certificate key pair, for example, Vserver-SSL-1, and click Open.
3. In the **Configure Virtual Server (SSL Offload)** dialog box, on the **SSL Settings** tab, under **Available**, select the certificate key pair that you want to bind to the virtual server. Then click **Add**.
4. Click **OK**.
5. Verify that the certificate key pair that you selected appears in the Configured area.

Configure support for Outlook web access

If you use Outlook Web Access (OWA) servers on your NetScaler appliance, you must configure the appliance to insert a special header field, FRONT-END-HTTPS: ON, in HTTP requests directed to the OWA servers, so that the servers generate URL links as `https://` instead of `http://`.

Note: You can enable OWA support for HTTP-based SSL virtual servers and services only. You cannot apply it for TCP-based SSL virtual servers and services.

To configure OWA support, do the following:

- Create an SSL action to enable OWA support.
- Create an SSL policy.
- Bind the policy to the SSL virtual server.

Create an SSL action to enable OWA support

Before you can enable Outlook Web Access (OWA) support, you must create an SSL action. SSL actions are bound to SSL policies and triggered when incoming data matches the rule specified by the policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create an SSL action to enable OWA support by using the CLI

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

```
- add ssl action <name> -OWASupport ENABLED

- show SSL action <name>
```

Example:

```
    > add ssl action Action-SSL-OWA -OWASupport enabled

    Done

    > show SSL action Action-SSL-OWA

    Name: Action-SSL-OWA

    Data Insertion Action: OWA
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    Support: ENABLED

    Done
```

Create an SSL action to enable OWA support by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Policies**.
2. In the details pane, on the **Actions** tab, click **Add**.
3. In the **Create SSL Action** dialog box, in the Name text box, type Action-SSL-OWA.
4. Under Outlook Web Access, select **Enabled**.
5. Click **Create**, and then click **Close**.
6. Verify that Action-SSL-OWA appears in the **SSL Actions** page.

Create SSL policies

SSL policies are created by using the policy infrastructure. Each SSL policy has an SSL action bound to it, and the action is carried out when incoming traffic matches the rule that has been configured in the policy.

Create an SSL policy by using the CLI

At the command prompt, type the following commands to configure an SSL policy and verify the configuration:

```
-  add ssl policy <name> -rule <expression> -reqAction <string>

-  show ssl policy <name>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example:

```
> add ssl policy-SSL-1 -rule ns_true -reqaction Action-SSL-OWA

Done

> show ssl policy-SSL-1

Name: Policy-SSL-1 Rule: ns_true

Action: Action-SSL-OWA Hits: 0

Policy is bound to following entities

1) PRIORITY : 0

Done
```

Create an SSL policy by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL > Policies**.
2. In the details pane, click **Add**.
3. In the **Create SSL Policy** dialog box, in the Name text box, type the name of the SSL Policy (for example, Policy-SSL-1).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. In **Request** Action, select the configured SSL action that you want to associate with this policy (for example, Action-SSL-OWA). The ns_true general expression applies the policy to all successful SSL handshake traffic. However, to filter specific responses, you can create policies with a higher level of detail. For more information about configuring granular policy expressions, see SSL actions and policies.
5. In **Named Expressions**, choose the built-in general expression ns_true and click **Add Expression**. The expression ns_true now appears in the Expression text box.
6. Click **Create**, and then click **Close**.
7. Verify that the policy is correctly configured by selecting the policy and viewing the Details section at the bottom of the pane.

Bind the SSL policy to the SSL virtual server

After you configure an SSL policy for Outlook Web Access, bind the policy to a virtual server that will intercept incoming Outlook traffic. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

Bind an SSL policy to an SSL virtual server by using the CLI

At the command prompt, type the following commands to bind an SSL policy to an SSL virtual server and verify the configuration:

```
-  bind ssl vserver <vServerName> -policyName <string>

-  show ssl vserver <name>
```

Example:

```
> bind ssl vserver Vserver-SSL-1 -policyName Policy-SSL-1

 Done

> show ssl vserver Vserver-SSL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Advanced SSL configuration for VServer Vserver-SSL-1:

DH: DISABLED

Ephemeral RSA: ENABLED

Refresh Count: 0

Session Reuse: ENABLED

Timeout: 120 seconds

Cipher Redirect: ENABLED

SSLv2 Redirect: ENABLED

ClearText Port: 0

Client Auth: DISABLED

SSL Redirect: DISABLED
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Non FIPS Ciphers: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: CertKey-SSL-1 Server Certificate

1) Policy Name: Policy-SSL-1 Priority: 0

1) Cipher Name: DEFAULT Description: Predefined Cipher Alias

Done
```

Bind an SSL policy to an SSL virtual server by using the GUI

Follow these steps:

1. Navigate to **Traffic Management > SSL Offload > Virtual Servers**.
2. In the details pane, select the virtual server (for example, Vserver-SSL-1), and then click **Open**.
3. In the **Configure Virtual Server (SSL Offload)** dialog box, click **Insert Policy**, and then select the policy that you want to bind to the SSL virtual server. Optionally, you can double-click the Priority field and type a new priority level.
4. Click **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Features at a glance

NetScaler features can be configured independently or in combinations to address specific needs. Although some features fit more than one category, the numerous NetScaler features can generally be categorized as application switching and traffic management features, application acceleration features, and application security and firewall features, and an application visibility feature.

To understand the order in which the features perform their processing, see Processing Order of Features section.

Application switching and traffic management features

Below are the application switching and traffic management features.

SSL Offloading

Transparently offloads SSL encryption and decryption from web servers, freeing server resources to service content requests. SSL places a heavy burden on an application's performance and can render many optimization measures ineffective. SSL offload and acceleration allow all the benefits of Citrix® Request Switching technology to be applied to SSL traffic, ensuring secure delivery of web applications without degrading end-user performance.

For more information, see SSL offload and acceleration.

Access Control Lists

Compares incoming packets to Access Control Lists (ACLs). If a packet matches an ACL rule, the action specified in the rule is applied to the packet. Otherwise, the default action (ALLOW) is applied and the packet is processed normally. For the appliance to compare incoming packets to the ACLs, you have to apply the ACLs. All ACLs are enabled by default, but you have to apply them in order for the NetScaler appliance to compare incoming packets against them. If an ACL is not required to be a part of the lookup table, but still needs to be retained in the configuration, it should be disabled before the ACLs are applied. An ADC appliance does not compare incoming packets to disabled ACLs.

For more information, see Access Control List.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Load Balancing

Load balancing decisions are based on a variety of algorithms, including round robin, least connections, weighted least bandwidth, weighted least packets, minimum response time, and hashing based on URL, domain source IP, or destination IP. Both the TCP and UDP protocols are supported, so the NetScaler appliance can load balance all traffic that uses those protocols as the underlying carrier (for example, HTTP, HTTPS, UDP, DNS, NNTP, and general firewall traffic). In addition, the ADC appliance can maintain session persistence based on source IP, cookie, server, group, or SSL session. It allows users to apply custom Extended Content Verification (ECV) to servers, caches, firewalls and other infrastructure devices to ensure that these systems are functioning properly and are providing the right content to users. It can also perform health checks using ping, TCP, or HTTP URL, and the user can create monitors based on Perl scripts. To provide high-scale WAN optimization, the CloudBridge appliances deployed at data centers can be load balanced through NetScaler appliances. The bandwidth and number of concurrent sessions can be improved significantly.

For more information, see Load Balancing.

Traffic Domains

Traffic domains provide a way to create logical ADC partitions within a single NetScaler appliance. They enable you to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments whose resources do not interact with each other. An application belonging to a specific traffic domain communicates only with entities, and processes traffic, within that domain. Traffic belonging to one traffic domain cannot cross the boundary of another traffic domain. Therefore, you can use duplicate IP addresses on the appliance as long as an addresses is not duplicated within the same domain.

For more information, see Traffic Domains.

Network Address Translation

Network address translation (NAT) involves modification of the source and/or destination IP addresses, and/or the TCP/UDP port numbers, of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your network's source IP addresses when data passes through the NetScaler appliance.

The NetScaler appliance supports the following types of network address translation:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

INAT: In Inbound NAT (INAT), an IP address (usually public) configured on the NetScaler appliance listens to connection requests on behalf of a server. For a request packet received by the appliance on a public IP address, the ADC replaces the destination IP address with the private IP address of the server. In other words, the appliance acts as a proxy between clients and the server. INAT configuration involves INAT rules, which define a 1:1 relationship between the IP address on the NetScaler appliance and the IP address of the server.

RNAT: In Reverse Network Address Translation (RNAT), for a session initiated by a server, the NetScaler appliance replaces the source IP address in the packets generated by the server with an IP address (type SNIP) configured on the appliance. The appliance thereby prevents exposure of the server's IP address in any of the packets generated by the server. An RNAT configuration involves an RNAT rule, which specifies a condition. The appliance performs RNAT processing on those packets that match the condition.

Stateless NAT46 Translation: Stateless NAT46 enables communication between IPv4 and IPv6 networks, by way of IPv4 to IPv6 packet translation and vice versa, without maintaining any session information on the NetScaler appliance. A stateless NAT46 configuration involves an IPv4-IPv6 INAT rule and an NAT46 IPv6 prefix.

Stateful NAT64 Translation: The stateful NAT64 feature enables communication between IPv4 clients and IPv6 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance. A stateful NAT64 configuration involves an NAT64 rule and an NAT64 IPv6 prefix.

For more information, see Configuring Network Address Translation.

Multipath TCP Support

NetScaler appliances support Multipath TCP (MPTCP). MPTCP is a TCP/IP protocol extension that identifies and uses multiple paths available between hosts to maintain the TCP session. You must enable MPTCP on a TCP profile and bind it to a virtual server. When MPTCP is enabled, the virtual server functions as an MPTCP gateway and converts MPTCP connections with the clients to TCP connections that it maintains with the servers.

For more information, see MPTCP (Multi-Path TCP).

Content Switching

Determines the server to which to send the request on the basis of configured content switching policies. Policy rules can be based on the IP address, URL, and HTTP headers. This allows

© 1997–2026 Citrix Systems, Inc. All rights reserved.

switching decisions to be based on user and device characteristics such as who the user is, what type of agent is being used, and what content the user requested.

For more information, see Content Switching.

Global Server Load Balancing (GSLB)

Extends the traffic management capabilities of a NetScaler® to include distributed Internet sites and global enterprises. Whether installations are spread across multiple network locations or multiple clusters in a single location, the NetScaler maintains availability and distributes traffic across them. It makes intelligent DNS decisions to prevent users from being sent to a site that is down or overloaded. When the proximity-based GSLB method is enabled, the NetScaler can make load balancing decisions based on the proximity of the client's local DNS server (LDNS) in relation to different sites. The main benefit of the proximity-based GSLB method is faster response time resulting from the selection of the closest available site.

For more information, see Global Server Load Balancing.

Dynamic Routing

Enables routers to obtain topology information, routes, and IP addresses from neighboring routers automatically. When dynamic routing is enabled, the corresponding routing process listens to route updates and advertises routes. The routing processes can also be placed in passive mode. Routing protocols enable an upstream router to load balance traffic to identical virtual servers hosted on two standalone NetScaler units using the Equal Cost Multipath technique.

For more information, see Configuring Dynamic Routes.

Link Load Balancing

Load balances multiple WAN links and provides link failover, further optimizing network performance and ensuring business continuity. Ensures that network connections remain highly available, by applying intelligent traffic control and health checks to distribute traffic efficiently across upstream routers. Identifies the best WAN link to route both incoming and outbound traffic based on policies and network conditions, and protects applications against WAN or Internet link failure by providing rapid fault detection and failover.

For more information, see Link Load Balancing.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TCP Optimization

You can use TCP profiles to optimize TCP traffic. TCP profiles define the way that NetScaler virtual servers process TCP traffic. Administrators can use the built-in TCP profiles or configure custom profiles. After defining a TCP profile, you can bind it to a single virtual server or to multiple virtual servers.

Some of the key optimization features that can be enabled by TCP profiles are:

- TCP keep-alive—Checks the operational status of the peers at specified time intervals to prevent the link from being broken.
- Selective Acknowledgment (SACK)— Improves the performance of data transmission, especially in long fat networks (LFNs).
- TCP window scaling— Allows efficient transfer of data over long fat networks (LFNs).

For more information on TCP Profiles, see Configuring TCP Profiles.

CloudBridge® Connector

The NetScaler CloudBridge Connector feature, a fundamental part of the Citrix OpenCloud framework, is a tool used to build a cloud-extended data center. The OpenCloud Bridge enables you to connect one or more NetScaler appliances or NetScaler virtual appliances on the cloud-to your network without reconfiguring your network. Cloud hosted applications appear as though they are running on one contiguous enterprise network. The primary purpose of the OpenCloud Bridge is to enable companies to move their applications to the cloud while reducing costs and the risk of application failure. In addition, the OpenCloud Bridge increases network security in cloud environments. An OpenCloud Bridge is a Layer-2 network bridge that connects a NetScaler appliance or NetScaler virtual appliance on a cloud instance to a NetScaler appliance or NetScaler virtual appliance on your LAN. The connection is made through a tunnel that uses the Generic Routing Encapsulation (GRE) protocol. The GRE protocol provides a mechanism for encapsulating packets from a wide variety of network protocols to be forwarded over another protocol. Then Internet Protocol security (IPsec) protocol suite is used to secure the communication between the peers in the OpenCloud Bridge.

For more information, see CloudBridge.

DataStream

The NetScaler DataStream feature provides an intelligent mechanism for request switching at the database layer by distributing requests on the basis of the SQL query being sent.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

When deployed in front of database servers, a NetScaler ensures optimal distribution of traffic from the application servers and Web servers. Administrators can segment traffic according to information in the SQL query and on the basis of database names, user names, character sets, and packet size.

You can configure load balancing to switch requests according to load balancing algorithms, or you can elaborate the switching criteria by configuring content switching to make a decision based on SQL query parameters, such as user name, database names, and command parameters. You can further configure monitors to track the states of database servers.

The advanced policy infrastructure on the NetScaler appliance includes expressions that you can use to evaluate and process the requests. The advanced expressions evaluate traffic associated with MySQL database servers. You can use request-based expressions (expressions that begin with MYSQL.CLIENT and MYSQL.REQ) in advanced policies to make request switching decisions at the content switching virtual server bind point and response-based expressions (expressions that begin with MYSQL.RES) to evaluate server responses to user-configured health monitors.

Note: DataStream is supported for MySQL and MS SQL databases.

For more information, see DataStream.

Application acceleration features

- AppCompress

  Uses the gzip compression protocol to provide transparent compression for HTML and text files. The typical 4:1 compression ratio yields up to 50% reduction in bandwidth requirements out of the data center. It also results in significantly improved end-user response time, because it reduces the amount of data that must be delivered to the user's browser.

- Cache Redirection

  Manages the flow of traffic to a reverse proxy, transparent proxy, or forward proxy cache farm. Inspects all requests, and identifies non-cacheable requests and sends them directly to the origin servers over persistent connections. By intelligently redirecting non-cacheable requests back to the origin web servers, the NetScaler appliance frees cache resources and increases cache hit rates while reducing overall bandwidth consumption and response delays for these requests.

  For more information, see Cache Redirection.

- AppCache

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Helps optimize web content and application data delivery by providing a fast in-memory HTTP/1.1 and HTTP/1.0 compliant web caching for both static and dynamic content. This on-board cache stores the results of incoming application requests even when an incoming request is secured or the data compressed, and then reuses the data to fulfill subsequent requests for the same information. By serving data directly from the on-board cache, the appliance can reduce page regeneration times by eliminating the need to funnel static and dynamic content requests to the server.

For more information, see Integrated Caching.

- TCP Buffering

  Buffers the server's response and delivers it to the client at the client's speed, thus offloading the server faster and thereby improving the performance of web sites.

Application security and firewall features

The following are the security and firewall features.

Denial of service (DoS) attack defense

Detects and stops malicious distributed denial-of-service (DDoS) attacks and other types of malicious attacks before they reach your servers, preventing them from affecting network and application performance. The NetScaler appliance identifies legitimate clients and elevates their priority, leaving suspect clients unable to consume a disproportionate percentage of resources and cripple your site. The appliance provides application-level protection from the following types of malicious attacks:

- SYN flood attacks
- Pipeline attacks
- Teardrop attacks
- Land attacks
- Fraggle attacks
- Zombie connection attacks

The appliance aggressively defends against these types of attacks by preventing the allocation of server resources for these connections. This insulates servers from the overwhelming flood of packets associated with these events.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The appliance also protects network resources from ICMP based attacks by using ICMP rate limiting and aggressive ICMP packet inspection. It performs strong IP reassembly, drops a variety of suspicious and malformed packets, and applies Access Control Lists (ACLs) to site traffic for further protection.

For more information, see AppQoE.

Content Filtering

Provides protection from malicious attacks for websites at the Layer 7 level. The appliance inspects each incoming request according to user-configured rules based on HTTP headers, and performs the action the user configured. Actions can include resetting the connection, dropping the request, or sending an error message to the user's browser. This allows the appliance to screen unwanted requests and reduces your servers' exposure to attacks.

This feature can also analyze HTTP GET and POST requests and filter out known bad signatures, allowing it to defend your servers against HTTP-based attacks.

Responder

Functions like an advanced filter and can be used to generate responses from the appliance to the client. Some common uses of this feature are generation of redirect responses, user-defined responses, and resets.

For more information, see Responder.

Rewrite

Modifies HTTP headers and body text. You can use the rewrite feature to add HTTP headers to an HTTP request or response, modify individual HTTP headers, or delete HTTP headers. It also enables you to modify the HTTP body in requests and responses.

When the appliance receives a request or sends a response, it checks for rewrite rules, and if applicable rules exist, it applies them to the request or response before passing it on to the web server or client computer.

For more information, see Rewrite.

Surge Protection

Regulates the flow of user requests to servers and controls the number of users that can simultaneously access the resources on the servers, queuing any additional requests once your

© 1997–2026 Citrix Systems, Inc. All rights reserved.

servers have reached their capacity. By controlling the rate at which connections can be established, the appliance blocks surges in requests from being passed on to your servers, thus preventing site overload.

For more information, see Surge Protection.

NetScaler Gateway

NetScaler Gateway is a secure application access solution that provides administrators granular application-level policy and action controls to secure access to applications and data while allowing users to work from anywhere. It gives IT administrators a single point of control and tools to help ensure compliance with regulations and the highest levels of information security across and outside the enterprise. At the same time, it empowers users with a single point of access—optimized for roles, devices, and networks—to the enterprise applications and data they need. This unique combination of capabilities helps maximize the productivity of today's mobile workforce.

For more information, see NetScaler Gateway.

Application Firewall

Protects applications from misuse by hackers and malware, such as cross site scripting attacks, buffer overflow attacks, SQL injection attacks, and forceful browsing, by filtering traffic between each protected web server and users that connect to any website on that web server. The application firewall examines all traffic for evidence of attacks on web server security or misuse of web server resources, and takes the appropriate action to prevent these attacks from succeeding.

For more information, see Application Firewall.

IP reputation

IP reputation is an essential tool for identifying IP addresses that generate unwanted requests. By using an IP reputation list, you can effectively reject requests from addresses known to have a negative reputation. This approach not only enhances the performance of the Web Application Firewall by streamlining the filtering process but also ensures that only genuine requests are processed. Also, it is possible to reset or drop unwanted requests or implement a responder policy to take specific actions based on the identified reputation of the requesting IP address.

For more information, see IP Reputation.

Application visibility feature

- NetScaler® Application Delivery Management

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler Application Delivery Management (ADM) is a high performance collector that provides end-to-end user experience visibility across Web and HDX (ICA) traffic. It collects HTTP and ICA AppFlow records generated by NetScaler appliances and populates analytical reports covering Layer 3 to Layer 7 statistics. NetScaler Console provides in-depth analysis for the last five minutes of real-time data, and for historical data collected for the last one hour, one day, one week, and one month.

HDX™ (ICA) analytic dashboard enables you to drill down from HDX Users, Applications, Desktops, and even from gateway-level information. Similarly, HTTP analytics provide a bird's eye view of Web Applications, URLs Accessed, Client IP Addresses and Server IP Addresses, and other dashboards. The administrator can drill down and identify the pain points from any of these dashboards, as appropriate for the use case.

- Enhanced Application Visibility Using AppFlow®

  The NetScaler appliance is a central point of control for all application traffic in the data center. It collects flow and user-session level information valuable for application performance monitoring, analytics, and business intelligence applications. AppFlow transmits this information by using the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information. AppFlow defines new Information Elements to represent application-level information.

  Using UDP as the transport protocol, AppFlow transmits the collected data, called *flow records*, to one or more IPv4 collectors. The collectors aggregate the flow records and generate real-time or historical reports.

  AppFlow provides visibility at the transaction level for HTTP, SSL, TCP, and SSL_TCP flows. You can sample and filter the flow types that you want to monitor.

  To limit the types of flows to monitor, by sampling and filtering the application traffic, you can enable AppFlow for a virtual server. AppFlow can also provide statistics for the virtual server.

  You can also enable AppFlow for a specific service, representing an application server, and monitor the traffic to that application server.

  For more information, see AppFlow.

- Stream Analytics

  The performance of your website or application depends on how well you optimize the delivery of the most frequently requested content. Techniques such as caching and compression help

© 1997–2026 Citrix Systems, Inc. All rights reserved.

accelerate the delivery of services to clients, but you must be able to identify the resources that are requested most frequently, and then cache or compress those resources. You can identify the most frequently used resources by aggregating real-time statistics about website or application traffic. Statistics such as how frequently a resource is accessed relative to other resources and how much bandwidth is consumed by those resources help you determine whether those resources must be cached or compressed to improve server performance and network utilization. Statistics such as response times and the number of concurrent connections to the application help you determine whether you must enhance server-side resources.

If the website or application does not change frequently, you can use products that collect statistical data, and then manually analyze the statistics and optimize the delivery of content. However, if you do not want to perform manual optimizations, or if your website or application is dynamic in nature, you need infrastructure that can not only collect statistical data but can also automatically optimize the delivery of resources based on the statistics. On the NetScaler appliance, this functionality is provided by the Stream Analytics feature. The feature operates on a single NetScaler appliance and collects run-time statistics based on the criteria that you define. When used with NetScaler policies, the feature also provides you with the infrastructure that you need for automatic, real-time traffic optimization.

For more information, see Action Analytics.

NetScaler Solutions

NetScaler solutions simplify the task of setting up frequently deployed configurations. Check this space from time to time for additional solutions.

This section includes the following solutions.

- Setting up NetScaler for Citrix Virtual Apps and Desktops
- Global Server Load Balancing (GSLB) Powered Zone Preference
- Anycast support in NetScaler
- Deploy digital advertising platform on AWS with NetScaler
- Enhancing Clickstream analytics in AWS using NetScaler

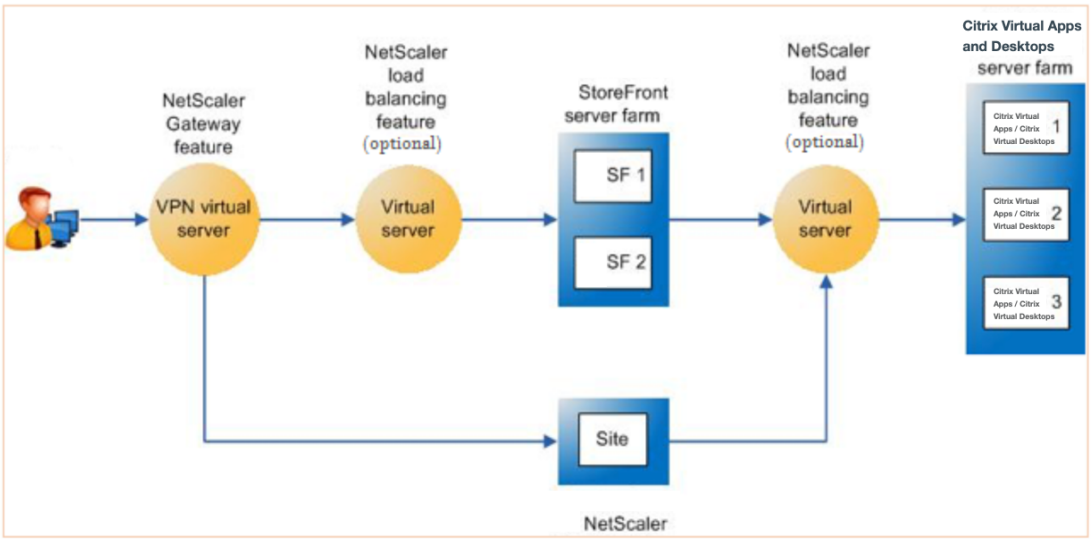
Setting up NetScaler for Citrix Virtual Apps and Desktops

NetScaler can provide load balanced, secure remote access to your Citrix Virtual Apps and Desktops applications. You can use the NetScaler load balancing feature to distribute traffic across the Citrix Virtual Apps and Desktops server. You can use the NetScaler Gateway feature to provide secure remote access to the servers.

NetScaler can also accelerate and optimize the traffic flow and offer visibility features that are useful for Citrix Virtual Apps and Desktops deployments.

Figure 1. NetScaler in Citrix Virtual Apps and Desktops setup

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The preceding figure shows the components involved in this deployment:

- **NetScaler® Gateway.** Provides the URL for user access, and provides security by authenticating the users. For more information, see About NetScaler Gateway.
- **NetScaler load balancing virtual server.** Load balances the traffic for the StoreFront servers. You can also deploy a load balancing virtual server in front of the Citrix Virtual Apps and Desktop servers to load balance key components such as XML Broker and Desktop Delivery Controller (DDC) server.
- **Citrix Virtual Apps and Desktops.** Provides the applications that your users want to access.

Prerequisites

- Citrix Virtual Apps™ and Desktop servers are configured and available.
- You have a working knowledge of NetScaler Gateway, NetScaler, Citrix Virtual Apps and Desktops, and StoreFront
- Make sure that you have configured a virtual server and a service and bound the service to the virtual server. For more information, see the following documents:
  - Configure Citrix Virtual Desktops™ for load balancing
  - Configure Citrix Virtual Apps™ for load balancing
- Make sure that the required communication ports are open between NetScaler, StoreFront, and the Citrix Virtual Apps and Desktops components. For the list of ports, see NetScaler communication ports.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Set up NetScaler for Citrix Virtual Apps and Desktops by using the GUI

To set up the NetScaler for Citrix Virtual Apps and Desktops by using the NetScaler GUI, follow this procedure.

Procedure:

1. Log on to NetScaler and on the **Configuration** tab click **XenApp and XenDesktop**.
2. On the **Details** pane, click **Get Started**. If the setup exists on the NetScaler, click the **Edit** link corresponding to each of the section that you want to modify.
3. Select the product (StoreFront) that in your deployment provides the interface for access to the Citrix Virtual Apps and Desktops applications.
4. Set up secure remote access.
    a. In the **NetScaler Gateway Settings** section, specify the details for the VPN virtual server and click **Continue**.
    b. In the **Server Certificate** section, choose an existing certificate or install a new certificate and click **Continue**.
    c. In the **Authentication** section, configure the primary authentication mechanism to be used and specify the server details or use an existing server and click **Continue**.
    d. In the **StoreFront™** section, specify the details of the server that provides the interface for accessing the applications and click **Continue**.
    e. You can use LB virtual server pointing to multiple SF servers as your StoreFront server.
5. Click **Done** to complete the configuration.

Global Server Load Balancing (GSLB) Powered Zone Preference

GSLB powered zone preference is a feature that integrates Citrix Virtual Apps and Desktops, StoreFront, and NetScaler to provide clients access to the most optimized data center based on the client location.

In a distributed Citrix Virtual Apps and Desktops deployment, StoreFront might not select an optimal data center when multiple equivalent resources are available from multiple data centers. In such cases, StoreFront randomly selects a data center. It can send the request to any of the Citrix

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Virtual Apps and Desktops servers in any data center, regardless of proximity to the client making the request.

The client IP address is examined when an HTTP request arrives at the NetScaler Gateway appliance. The real client IP address is used to create the data center preference list that is forwarded to StoreFront. If the NetScaler appliance is configured to insert the zone preference header, StoreFront 3.5 or later can use the information provided by the appliance to reorder the list of delivery controllers and connect to an optimal delivery controller in the same zone as the client. StoreFront selects the optimal gateway VPN virtual server for the selected data center zone, adds this information to the ICA file with appropriate IP addresses, and sends it to the client. StoreFront then tries to launch applications hosted on the preferred data center's delivery controllers before trying to contact equivalent controllers in other data centers.

For more information about configuring this solution, click here.

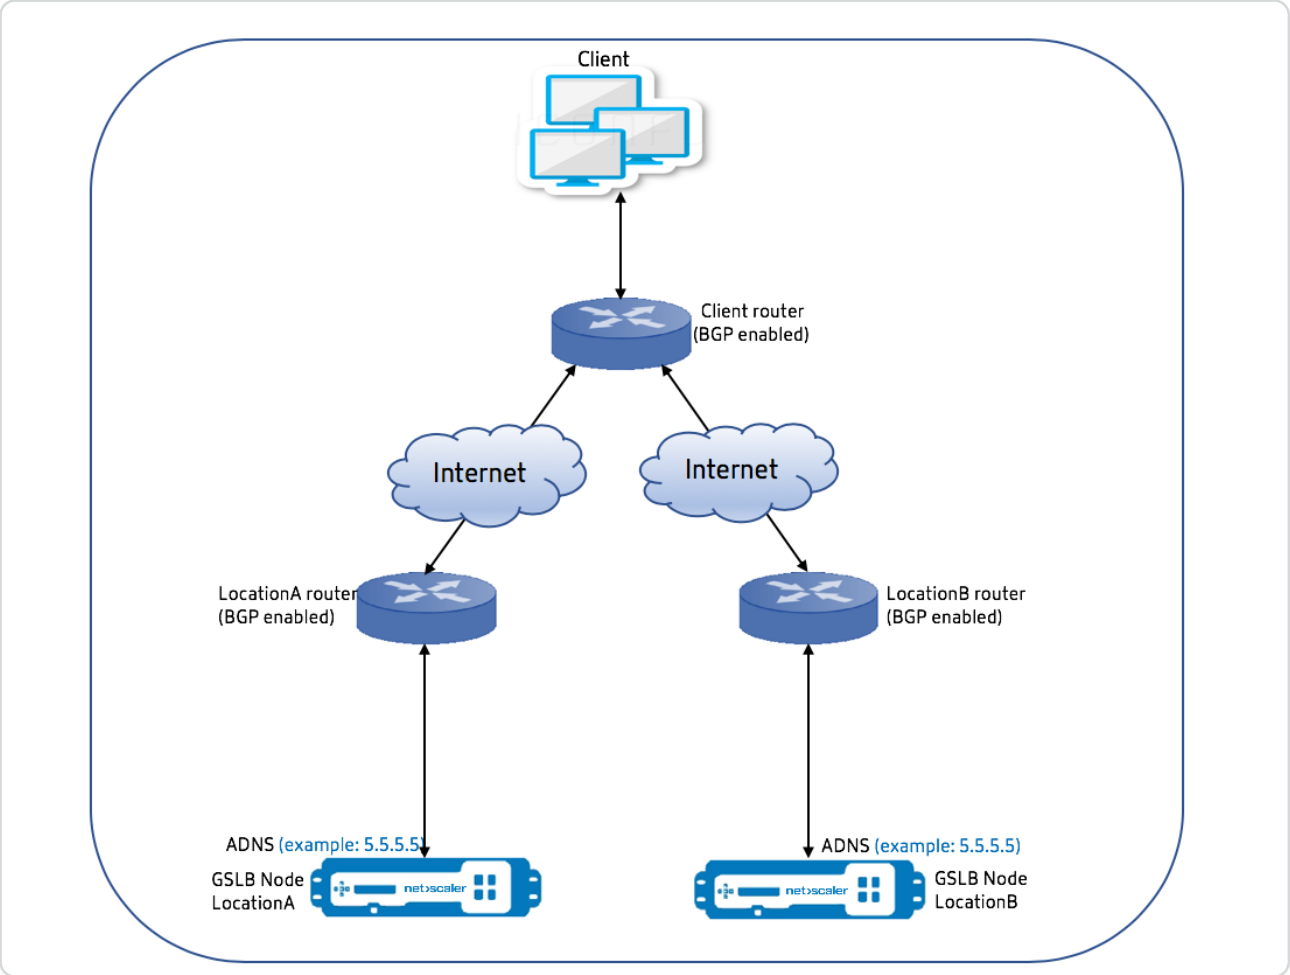
Anycast support in NetScaler

Anycast is a type of network where a set of servers shares an IP address. The client request is directed to the topographically closest server based on their routing tables. This routing reduces latency issues, ensures high availability, and minimizes downtime.

NetScaler supports anycast network with Global Server Load Balancing (GSLB) and DNS features.

The following diagram illustrates a topology diagram of Anycast in NetScaler.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Anycast GSLB

The NetScaler GSLB feature provides load balancing across globally distributed sites along with disaster recovery and ensures continuous availability of applications.

During an outage, GSLB provides immediate disaster recovery by routing traffic to the closest or the best performing data center. However, GSLB cannot control the following:

- How the DNS traffic is routed to GSLB nodes in different geographical locations.
- How much latency is getting added while DNS queries get routed to GSLB nodes.

In a typical GSLB setup, each data center has a GSLB node configured with the site-specific Authoritative Domain Name Server (ADNS) to receive DNS queries. Each site's ADNS is configured as the nameserver in the DNS resolver. As the number of GSLB nodes increases, the number of nameserver records also increase. In such cases, if there is a failure of a data center, LDNS has to retry resolution with a different nameserver. This retry adds to the latency in DNS resolution. Also, every time a GSLB node is added, the nameserver records must be updated.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To overcome these drawbacks, you can use Anycast ADNS. In Anycast ADNS, a single ADNS IP address is used for all GSLB nodes and the DNS traffic is routed to GSLB nodes using dynamic routing.

For example, if a GSLB site is DOWN, the routing table is updated and route to this site is removed. As a result, The DNS queries are not sent to the sites that are DOWN. As a result, there are no retries.

If a new GSLB node is added, the new node is assigned the same ADNS IP address. The dynamic routing automatically updates the routing tables with routes to new sites based on the routing algorithms. Hence, you do not have to update the DNS name server records. The rollout of new GSLB sites is made simpler and faster with Anycast.

How to configure an ADNS IP address in an anycast mode

Enable host routing on the ADNS IP in a NetScaler appliance, and set the appropriate Route Health Injection (RHI) level. Mostly, there would not be any virtual servers on the ADNS IP and therefore RHI level must be selected as NONE. Enabling host route on the ADNS IP makes it a kernel route. You can then enable the dynamic routing of choice and configure the routing protocol to redistribute the kernel routes.

ADNS IP configuration – Example

At the command prompt, type;

```
add service adns_public 5.5.5.5 ADNS 53

set ip 5.5.5.5 -hostRoute ENABLED -vserverRHILevel ALL_VSERVERS
```

BGP configuration in GSLB site – Example

Anycast DNS

You can use Anycast DNS for DNS proxy virtual servers on NetScaler. When there are multiple DNS name servers configured, the DNS resolver responds based on round robin method. For example, if the resolver does not receive any response from the first server, it switches to the second server after the configured timeout value expires. The switching from first server to second server adds to the latency in DNS resolution. If the DNS resolvers are configured with Anycast, then this latency can be eliminated.

DNS configuration – Example

At the command prompt, type;

```
add lb vserver dns DNS 5.5.5.50 53

set ip 5.5.5.50 -hostRoute ENABLED -vserverRHILevel ALL_VSERVERS
```

Deploy digital advertising platform on AWS with NetScaler

With the evolving nature of digital platforms, a wide range of advertising applications are available. For example, social media, direct mail, videos, banners, pops, interstitials, rich media and so on. Advertisers are embracing video advertising networks at a fast pace, constituting nearly 40% of the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

advertisement traffic. But with more usage of mobiles by the modern users, running video ads on the mobile platform has seen considerable surge.

The digital advertising platforms face several challenges. Some of the challenges are:

- Security threats
- High operational costs
- Wide range of devices are available to send traffic over the internet. The different protocols for real-time communication pose the following challenges:
    - webRTC
    - Adaptive streaming
    - UDP for video, where WebRTC uses UDP over HTTP

To deal with the complex behavior of advertising platforms, NetScaler solution with its whole suite of capabilities and features well integrated with AWS, provides an instant, secure, and reliable access to digital advertisement inventory, anywhere and anytime. NetScaler plays a critical role in delivering the SaaS and web apps for digital platforms.

Digital advertising platform integration with NetScaler

Digital advertising platform overview

The digital advertising platform consists of the following key components:

- Ad exchange
- Ad network
- Demand side platform (DSP)
- Supply side platform (SSP)
- Real time bidding (RTB) systems

An overview of the process followed in an advertising system is as follows.

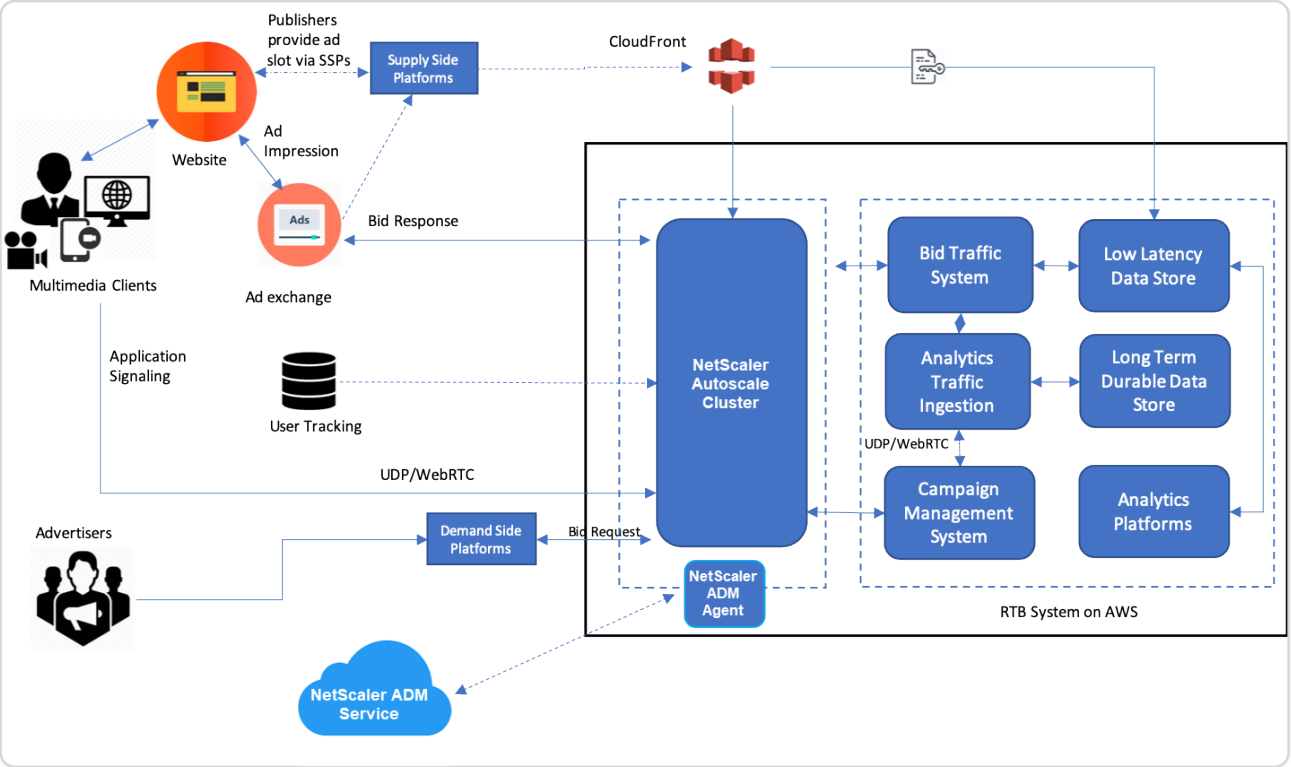
- The first transaction happens when the user visits the website.
- This triggers a bid/advertisement request (including user's demographic information) that is sent to the ad server or publisher contacting an ad exchange.
- The Ad publishers send the advertisement request to an Ad exchange through SSPs.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The Ad exchange submits this request and the accompanying data to DSP telling there is an impression or advertisement request available. Therefore, multiple advertisers can automatically submit bids in real time to place their advertisements.
- Meanwhile, the advertisers must set up their campaigns in DSP. Use the information about the user from Data Management Platform (DMP) to assess the amount they are willing to pay for delivering an advertisement to the user.
- DSPs submit these real-time bids on each advertisement impression because it is served to the advertisement exchange.
- Whichever bidder bids the most within a time period set by the Ad exchange or SSPs, gets an advertisement slot by the publishers to serve their advertisements. Otherwise, they lose the opportunity to get the right advertisement for their key demographic.

How digital advertising platform is integrated with NetScaler

The following diagram illustrates how the different components of advertising platform communicate with NetScaler and NetScaler Application Delivery Management (ADM) to serve online advertisements.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

How NetScaler contributes

In the advertisement publishing process, NetScaler solution helps in handling and processing the inconsistent influx of bid traffic. It acts as an entry point for all traffic to ensure scalability and availability across the availability zones. To cater to the elastic nature of advertising traffic, it is deployed in an autoscaling group in front of web applications and database servers.

The advertising platform on AWS with NetScaler solution allows you to get the real-time performance, high scalability, and high availability across the globe. You can buy and sell rich media, video, mobile, and native advertisements in real time. It reduces the overall operational cost and latency involved in running an Advertising platform. It is the best performing proxy with the rich capabilities of gracefully removing the back-end servers during Autoscale, connection multiplexing, and ensuring that the end-user traffic never gets impacted. NetScaler supports load balancing the HTTP, UDP, WebRTC, and RTSP protocols that are used in the advertising platforms.

NetScaler fits coherently into the AWS environment with the following key attributes:

- Content switching – Switch to the right platform based on host name.
- Security protection – Use web application firewall (WAF) functionality, rate limiting (through Client IP), and protection against DDoS attacks.
- Autoscaling of both front-end and back-end traffic.
- End-to-end visibility, and anomaly detection across ADC appliances by utilizing ADM.
- Low latency.

How NetScaler Console contributes

NetScaler utilizes NetScaler Console to overcome the following challenges faced by the digital advertising platforms:

- Identify the trend deviations from expected performance
- Real-time application performance analysis
- Capacity monitoring

Advantages of advertising platform integration with NetScaler and ADM

The NetScaler solution offers the following capabilities and benefits to a digital advertising platform vendor.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Low cost

- Integrated with AWS Autoscaling service, the NetScaler VPX instance can scale up or down your front-end and back-end resources automatically. This provides a zero-touch configuration catering to the elasticity of advertising platforms.
- Consolidation of delivering all types of traffic from a single point.

For more information on AWS autoscaling, see Add back-end AWS Autoscaling service.

High availability

- If one Availability Zone becomes unavailable, NetScaler applies its fault tolerance ability to autodetect the servers in another availability zone, without any traffic interruption.
- Also, It gracefully terminates servers avoiding the loss of client connections.

For more information, see How high availability on AWS works.

Application performance analytics

NetScaler Console intelligent analytics and application performance analytics ensures to:

- Gain visibility into the issues (server response anomalies, 5XX errors, and so on) plaguing the end user experience.
- Alert the administrator to take corrective actions immediately.

For more information, see Performance indicators for application analytics.

Rich firewall security

Most common security vulnerabilities occur in web applications rather in networks. It is vital to protect your web applications from unauthorized access such as bots, data thefts, and application layer attacks.

NetScaler provides comprehensive and integrated Layer 4 to Layer 7 security that includes:

- Web App Firewall (WAF) to protect your web applications, identify, and mitigate malicious bots with regularly updated bot signatures and behaviour-based detection.
- Rate limiting to prevent an advertising platform from being overwhelmed.

For more information, see NetScaler Web App Firewall.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Select the right AWS instance type for advertising platform

Choose the right AWS instance type for ADC depending on the following two factors:

- Number of users simultaneously accessing the advertising platform.
- Average number of users on the platform.

The NetScaler can be deployed in various EC2 instances, which include c5, c5n, m5, and so on. For advertising platforms, use the following AWS instance types:

- c5 or c5n is appropriate for handling SSL heavy traffic.
- c5.large can handle up to 1000 SSL TPS.

For more information, see VPX-AWS support matrix.

Enhancing Clickstream analytics in AWS using NetScaler

Customers are increasingly accessing the company products through various applications such as Mobile apps, SaaS apps and so on. Therefore, applications can become a landmine of customer experience data. To track customer behavior online, customer-centric companies form data-driven profiles for each of their customers using this customer behavior data.

A clickstream is a sequence or stream of events that represent user actions (clicks) on a website or a mobile application. However, the scope of clickstream extends beyond clicks. It includes product searches, impressions, purchases, and any such events that might be of relevance to the business. Mere collecting and storing the customer experience data is not of much value. There is a need to distribute the highly complex data seamlessly to the right vendors at the right time. Businesses can derive value from the data and quickly take conscious decisions to improve upon their strategies. Therefore companies increasingly use clickstream analytics to glean insights into the customer experience journey of the apps.

This document provides you a good understanding on why Clickstream data is of utmost importance, how it is collected, stored, distributed, and transformed into meaningful and actionable analytics.

NetScaler integrates with NetScaler Console, and adds value to AWS services such as Amazon Kinesis Data Firehose to equip businesses with the best-in-class analytics solution that revolves around user’s Clickstreams.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This NetScaler solution helps you to solve complex business issues efficiently and with extreme simplicity. NetScaler and AWS Kinesis help to capture the issues with the poorly designed workflow. NetScaler Console helps to capture web app and network performance related issues by applying relevant filters. Conjunction of NetScaler with NetScaler Console and AWS Kinesis helps you to manage and analyze the huge influx of clickstream data in each phase. This solution is highly available, scalable, robust, and ensures the delivery is continuous and secure. Thus, you can derive actionable insights.

Why businesses opt for Clickstream analytics?

Businesses opt for clickstream primarily to understand how users interact with the application, and to get insights on improving the goals of the application. Clickstream Analytics is an information retrieval use case that tracks your user's behavior, navigation habits, and so on. Clickstream analytics gives you information on:

- Which link your customers are clicking more often and at what point in time.
- Where was the visitor before reaching my website?
- How much time did the visitor spend on each page?
- When and where did the visitor click the "back" button on the web browser?
- What items did the visitor add to (or remove from) their shopping cart?
- From which page did the visitor exit my website?

Analytics service to manage Clickstream data using Amazon Kinesis

You can use Amazon Kinesis to perform clickstream analytics. Amazon kinesis enables clickstream analytics with the following services:

- Amazon Kinesis Data Firehose
- Amazon Kinesis Data Analytics
- Amazon Kinesis Data Streams

With Amazon Kinesis, you can collect and analyze your huge data sets at any scale. AWS Kinesis can handle data from various sources, such as:

- Mobile and web applications (for example, Gaming, ecommerce)
- IoT devices

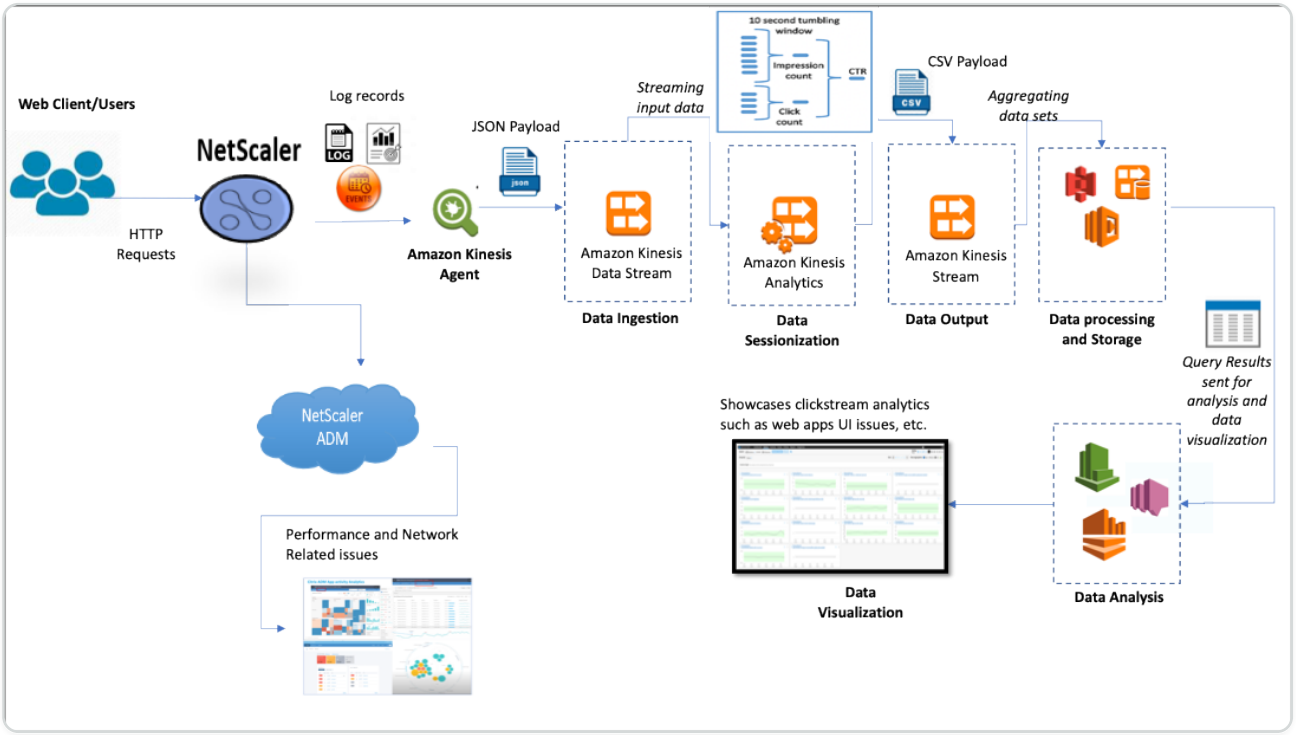
© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Social networking applications
- Financial trading services
- Geospatial services

How NetScaler enables Clickstream analytics

The NetScaler solution collates and delivers information securely on the activities of users, such as, websites visited, the bandwidth spent, navigation flow. Companies analyze this high throughput and continuous clickstream data to corroborate the effectiveness of the following:

- Site layout
- Marketing campaigns
- New application features



With the NetScaler's ability to provide a resilient network protection for enterprise environments, the server cost is reduced manifolds by offloading computationally intensive tasks, and running sessions on this data. Thereby helping companies to identify events in real-time with high availability, security, and low latency always.

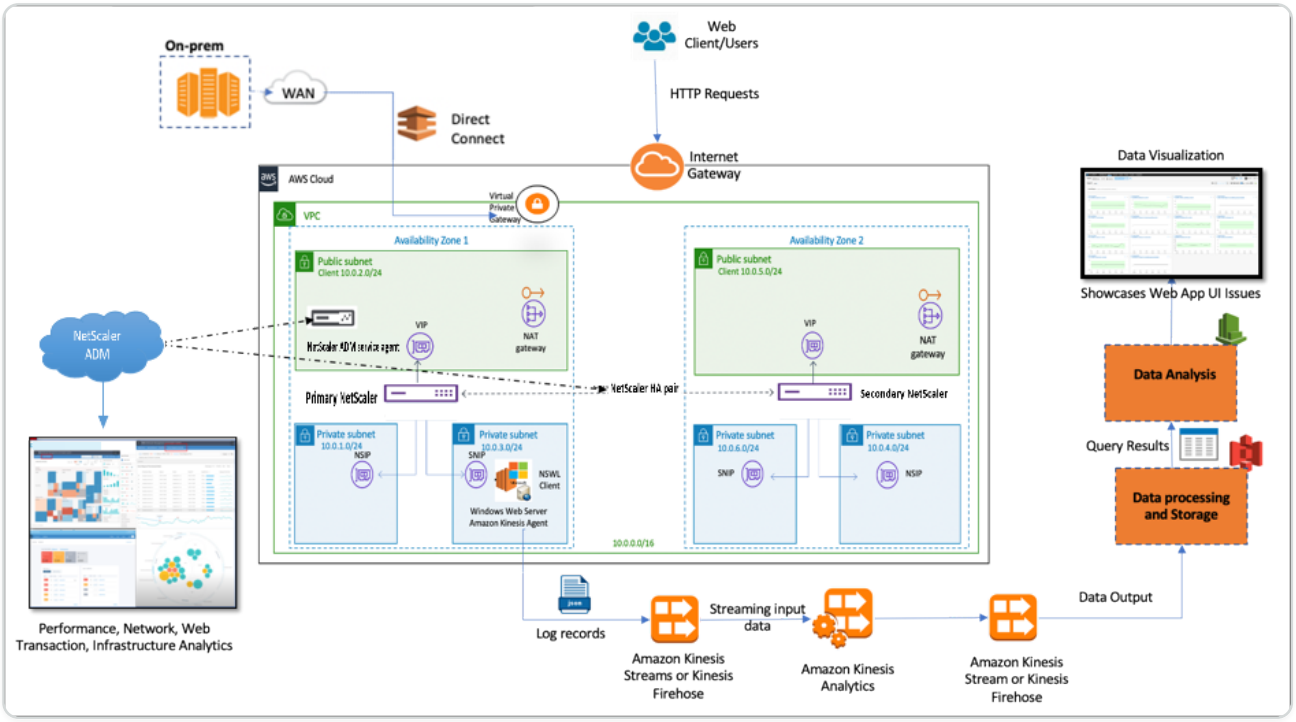
For configuration information, see Configure the NetScaler solution for clickstream analytics.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How NetScaler and NetScaler Console complement the AWS environment

The following diagram illustrates the end-to-end user workflow to perform Clickstream analytics in AWS infrastructure. This diagram helps you understand the following processes:

- How user interacts with NetScaler
- How NetScaler captures user's actions and generates clickstream data
- How the clickstream data is delivered to AWS services (Amazon Kinesis)
- How Amazon Kinesis processes the data logs and stores them to produce meaningful clickstream analytics



The NetScaler seamlessly integrates into the AWS environment and NetScaler Console that helps businesses to be compatible with variable volume and diverse nature of the clickstream data. It provides services to load and analyze streaming knowledge with simplicity. You can also create custom streaming knowledge applications for specialized desires.

Amazon Kinesis

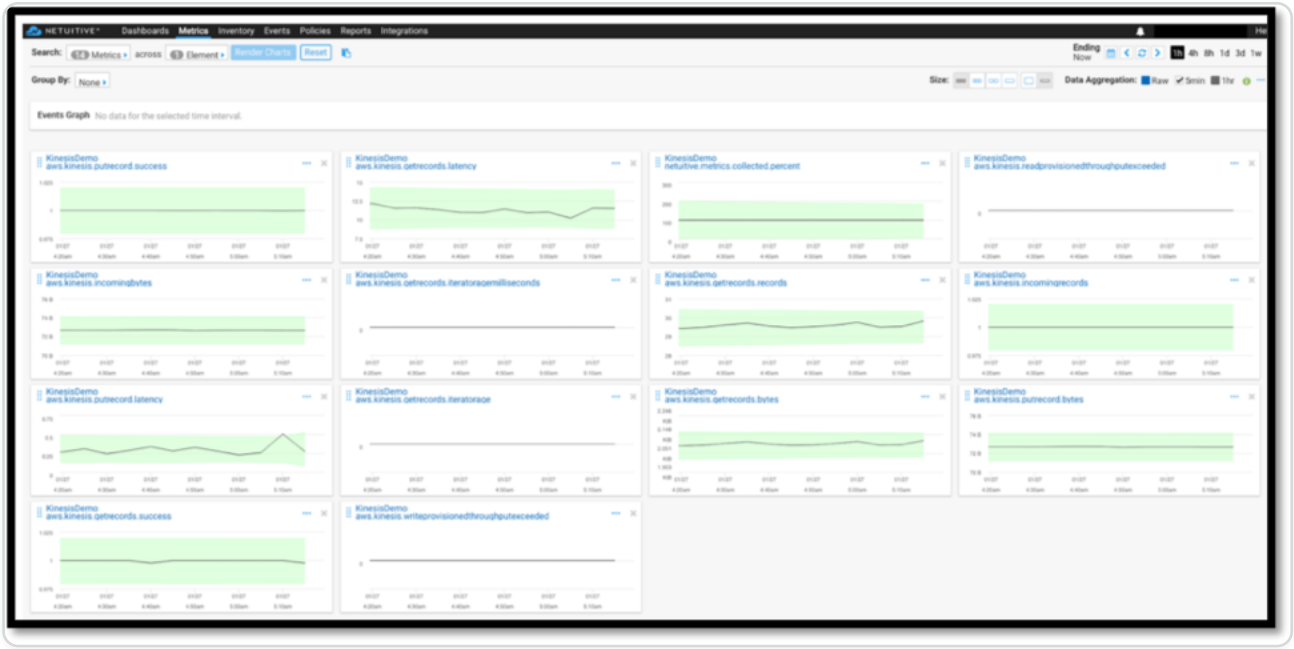
The AWS environment has different services that perform analytics on the user events, logs, and metrics captured by NetScaler. The data can be website clickstreams, financial transactions, social media feeds, IT logs, and location-tracking events.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Amazon Kinesis Data Streams perform analytics in scenarios that involve scalable and durable real-time data streaming that can continuously capture GB of data per second from several sources.
- Amazon Kinesis Data Analytics can be used for scenarios with lower latency between the session generation because it takes less time to aggregate various data sets.
- Amazon Kinesis Agent for Microsoft Windows collects, parses, filters, and streams input data to Kinesis data streams.
- Once the data is up in the cloud, you can implement the exact data pipeline to get the results you want. For example, you can use this information in Amazon Quick Sight, which is a visualization tool that is used to build dashboards.

The AWS Kinesis dashboard provides the following offerings:

- Showcases web apps UI issues
- Near real-time visualizations of web usage metrics such as events per hour, visitor count, and referrers.
- Session-wise analysis



NetScaler Console Analytics

By utilizing NetScaler Console with NetScaler, you can get a single-pane-of-glass view across all the business environments. NetScaler captured logs are fed into NetScaler Console, that treats your individual applications as a single entity. You can gain valuable insights and effectively troubleshoot issues with the following ADM capabilities:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Intelligent analytics
- Web transaction analytics
- Anomaly detection
- Performance and network-related issues

The following ADM service dashboard helps you gain valuable insights to effectively troubleshoot the issues.

How NetScaler Console correlates with Clickstream analytics

Clickstream analytics data can be correlated with ADM analytics to describe, predict, and improve application's performance.

For more information on NetScaler Console, see NetScaler Console

For example, an organization while analyzing their logs notice that most of the users are abandoning their sites. But to find the root cause behind this user behavior, they need to find out which part of their application is performing bad. With clickstream analytics data and ADM

© 1997–2026 Citrix Systems, Inc. All rights reserved.

analytics, you can derive the following insights to analyze the reason behind users abandoning a site:

- Is the user abandoning due to latency, 5xx errors?
- Are there any SSL Handshake errors?
- Is there some part of the application that has performance or network related issues?
- Is there a 404 error, or the page loading time takes forever to respond, and so on.
- Are customers facing server response anomalies?

NetScaler Console service provides Web Insights that allow IT administrators to speed up solving issues with the following features:

- Provides integrated and real-time monitoring of all web applications that served by the NetScaler.
- Get a holistic view on the application performance w.r.t. time, latency, and the usual user's behavior through observability tools (such as global service graph).
- Perform intelligent analytics to understand server response anomalies.
- SSL insights contribute towards resolving 5xx and 4xx errors.
- To maintain records of all web sessions that include:
  - Detailed logs of every web transaction
  - Search capability to find relevant logs
  - Ability to isolate an ADC-to-end user vs. ADC-to-server problem

Types of data exported by ADC for Clickstream analytics

NetScaler captures the different sources that generate varied forms of data, which are as follows:

- Web server logs

  Web server logging feature sends logs of HTTP and HTTPS requests to a client system for storage and retrieval. These logs contain huge amount of data, which is difficult to comprehend and make sense out of it. Analytical tools help in understanding and bring value from it. For configuration details, see the **Web logging configuration section** in this document.

- Syslogs

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The primary use of syslogs is for systems management. Proactive syslog monitoring pays off because it significantly reduces downtime of servers and other devices in your infrastructure. Syslog identifies critical network issues and reports them proactively.

- Access logs

  The access logs store information about events that occurred on your web server. For instance, when someone visits your website, a log is recorded and stored to provide the web server administrator with information such as the IP address of the visitor, what pages they were viewing, status codes, browser used. To access logs might be overwhelming, if there is lack of appropriate knowledge to understand them. You can program your system to integrate with:

  - NetScaler for seamless delivery
  - Kinesis for actionable insights that is useful for businesses

- Audit logs

  The Audit Logging feature enables you to log the NetScaler states and status information collected by various modules in the kernel and in the user-level daemons.

- Error logs

  The error logs file is an aid for administrators to provide more information regarding a specific error that has occurred on the web server.

Configure the NetScaler solution for clickstream analytics

The Web server logging feature enables you to send logs of HTTP and HTTPS requests to a client system for storage and retrieval.

To configure the NetScaler for web server logging you must:

- Enable web logging feature
- Configure the size of the buffer to temporarily store the log entries because the Web log server runs on the NetScaler.

To configure web server logging by using CLI:

1. Enable the web server logging feature.

   ```
   enable ns feature WL
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Modify/Configure the buffer size for storing the logged information.

```
set ns weblogparam -bufferSizeMB 60
```

3. Install the NetScaler web logging (NSWL) client. For more information, see Installing the NetScaler web logging (NSWL) client
4. Install the NSWL client on Windows by performing the following operations on the system where you downloaded the package.

   a. Extract and copy the nswl_win-< release number >-< build number >.zip file from the package to a Windows system on which you want to install the NSWL client.

   b. On the Windows system, unzip the file in a directory (referred as < NSWL-HOME>). Bin, samples, and other directories are extracted.

   c. At the command prompt, run the following command from the < NSWL-HOME >\bin directory:

```
nswl -install -f < path of the log.conf file >\log.conf
```

NOTE:

To uninstall the NSWL client, at the command prompt, run the following command from the < NSWL-HOME >\bin directory:

```
nswl -remove
```

5. After you install the NSWL client, configure the NSWL client using the NSWL executable. These configurations are stored in the NSWL client configuration file (log.conf).

   Run the following commands from the directory in which the NSWL executable is located:

```
\ns\bin
```

6. In the NSWL client configuration file (log.conf), add the NetScaler IP address (NSIP) from which the NSWL client collects logs by running the following in the client system command prompt:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
nswl -addns -f < Path to the configuration(log.conf) file >\log.conf
```

7. Input the NetScaler appliance's NSIP (IP address), user name as `nsroot` and password as "the instance id/your set password" so that:
   - NSWL client connects to the ADC after you add the NetScaler® IP address (NSIP) to the NSWL configuration file
   - ADC buffers the HTTP and HTTPS request log entries before sending them to the client.
   - The client can filter the entries(by modifying log.conf file) before storing them.

Note

Change the default password for NetScaler and then proceed with the configuration. Type the following command to change the password:

```
set system user nsroot -password &lt;your password>
```

Configuring the Amazon Kinesis agent

Perform the following steps in the AWS web console to configure the Amazon Kinesis agent:

1. Create a configuration file (appsettings.json) and deploy it. Configuration files define sets of sources, sinks, and pipes that connect sources to sinks, along with optional transformations.

   The following example is a complete `appsettings.json` configuration file that configures Kinesis Agent to stream Windows application log events to Kinesis Data Firehose.

```
{

"Sources": [

    {

        "Id": "NSWLog",

        "SourceType": "DirectorySource",

        "Directory": "C:\\Users\\Administrator\\Downloads\
\nswl_win-13.0-52.24\\bin",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        "FileNameFilter": "*.log"

        "RecordParser": "TimeStamp",

        "TimestampFormat": "yyyy-MM-dddd HH:mm:ss.ffff", //Optional
parameter required only by the timestamp record parser

        "TimeZoneKind": "UTC", //Local or UTC

        "SkipLines": 0 //Skip a number of lines at the beginning of
each file

    }

    ],

"Sinks": [

    {

        "Id": "ApplicationLogKinesisFirehoseSink",

        "SinkType": "KinesisFirehose",

        "StreamName": "Delivery-ik-logs",

        "AccessKey": "Your Access Key",

        "SecretKey": "YourSecretKey",

        "Region": "ap-south-1"

    }

    ],

"Pipes": [

    {

    "Id": "ApplicationLogSourceToApplicationLogKinesisFirehoseSink",

    "SourceRef": "ApplicationLogSource",
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    "SinkRef": "ApplicationLogKinesisFirehoseSink"

    }

    ],

"Telemetrics":

    {

    "off": "true"

    }

}
```

2. Set up a Kinesis Agent on data sources to collect data and send it continuously to Amazon Kinesis Firehose/Kinesis Data Analytics. For more information, see Getting Started with Amazon Kinesis Agent for Microsoft Windows.
3. Create an end-to-end data delivery stream using Amazon Kinesis Firehose. The delivery stream transmits your data from the agent to the destination. The destination includes Amazon Kinesis Analytics, Amazon Redshift, Amazon Elasticsearch service, and Amazon S3. For the Source, choose **Direct PUT or other sources** to create a Kinesis Data Firehose delivery stream.
4. Process the incoming log data using SQL queries in Amazon Kinesis Analytics.
5. Load processed data from Kinesis Analytics to Amazon Elasticsearch Service to index the data.
6. Analyze and visualize the processed data using Visualization tools, such as Kibana and AWS QuickInsight Services.

NetScaler cloud native solution for microservices based on Kubernetes

As companies transform to innovate faster and get closer to customers, they are rearchitecting their internal process and breaking down boundaries within their organization. They are removing silos to pull together the right skill sets in the same team. One of the goals is to create and deliver software applications with speed, agility, and efficiency. In this regard, modern application architectures based on microservices are being adopted by a growing number of enterprises. Using a microservices architecture, you can create applications as sets of loosely coupled services which can be deployed, updated, and scaled independently.

Cloud native is an approach that relies on the microservices architecture for building and deploying applications with the following key attributes:

- Deploys applications as loosely coupled microservices or containers
- Involves a very high degree of automation
- Implements agile DevOps processes and continuous delivery workflows
- Centers around APIs for interaction and collaboration

How does Kubernetes help in the cloud native journey?

To provide the desired levels of agility and stability, cloud native applications require high levels of infrastructure automation, security, networking, and monitoring. You need a container orchestration system that can efficiently manage containers at a large scale. Kubernetes has emerged as the most popular platform for container deployment and orchestration. Kubernetes abstracts the complex task of running, deploying, and managing containers from developers and operators and automatically schedules containers among a cluster of nodes. Kubernetes and the cloud native computing foundation (CNCF) ecosystem helps you to build a platform for cloud native solutions.

Some of the key benefits of using Kubernetes:

- Simplifies application deployment be it on-premises, hybrid, or public cloud infrastructure

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Accelerates application development and deployment
- Increases agility, flexibility, and scalability of applications

What is NetScaler cloud native solution?

To maximize the benefits of using Kubernetes in production, you need to integrate Kubernetes with several tools, vendor-sourced, and open-source components. Ensuring production grade reliability and security for their cloud native application is a challenge faced by many organizations. NetScaler offers a NetScaler cloud native solution to address the challenges in a Kubernetes production environment.

NetScaler cloud native solution leverages the advanced traffic management, observability, and comprehensive security features of NetScaler to ensure enterprise grade reliability and security. It can provide complete visibility to application traffic in your Kubernetes environment, render immediate feedback, and help gain meaningful insights about the application performance.

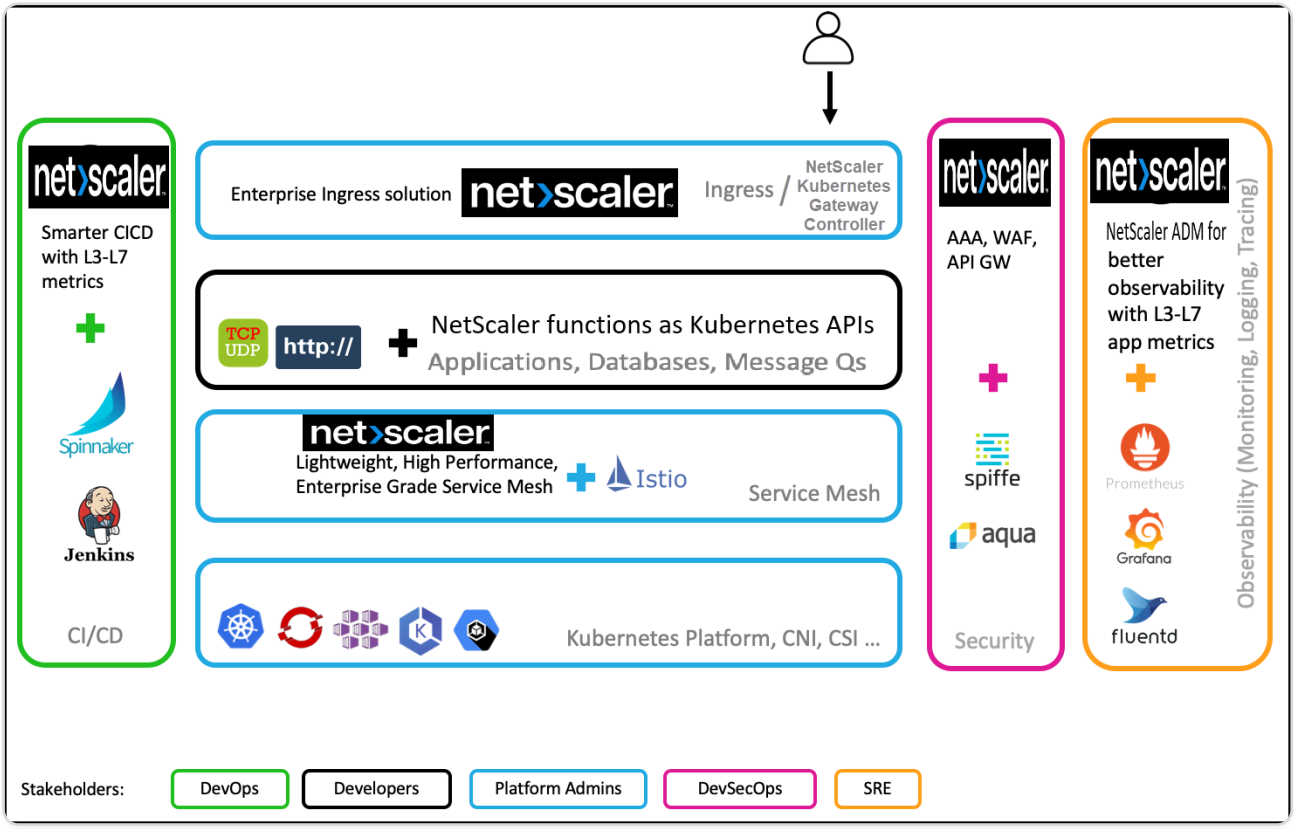
The following table lists the key requirements of different stakeholders while implementing an Ingress solution.

STAKEHOLDERS	JOB FUNCTION	NEEDS
Platform administrators	Ensure availability of Kubernetes clusters	Simpler ways to manage applications deployed across multiple clusters, operation, and platform life cycle management
DevOps	Accelerate the deployment of applications to production	Integration with CI/CD pipeline, support for deployment techniques like Canary and blue-green for faster deployment
Developers	Develop and test microservices	Ways to bring traffic into the Kubernetes cluster, tracing and debugging, rate limiting for applications, and authentication for applications

© 1997–2026 Citrix Systems, Inc. All rights reserved.

STAKEHOLDERS	JOB FUNCTION	NEEDS
SREs	Ensure availability of applications to meet service level agreements	Advanced telemetry for applications and infrastructure
SecOPs	Ensure security compliance	Secure Ingress traffic, API protection, service mesh for secure communication between microservices inside the Kubernetes cluster

The following diagram explains the NetScaler cloud native solution and how it addresses the various challenges faced by stakeholders in their cloud native journey.



NetScaler cloud native solution provides the following key benefits:

- Provides an advanced Kubernetes Ingress solution that caters to the needs of developers, SREs, devOps, and network or cluster administrators.
- Eliminates the need to rewrite legacy applications based on TCP or UDP traffic while moving them into a Kubernetes environment.
- Secures applications with NetScaler policies exposed as Kubernetes APIs.
- Helps to deploy high performing microservices for North-South traffic and East-West traffic.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Provides an all-in-one view of all microservices using NetScaler Console service graph.
- Enables faster troubleshooting of microservices across different kinds of traffic including TCP, UDP, HTTP, HTTPS, and SSL.
- Secures APIs.
- Automates CI/CD pipeline for Canary deployments.
- Provides out of the box integrations with CNCF open-source tools.

For more information on the various cloud native solutions offered by NetScaler, see the following links:

- Kubernetes Ingress solution
- NetScaler Kubernetes Gateway Controller
- Service mesh
- Solutions for observability
- API gateway for Kubernetes

Components of NetScaler cloud native solution

The following table explains the major components of NetScaler cloud native solution:

COMPONENT	DESCRIPTION
NetScaler Ingress Controller	This container is an implementation of the Kubernetes Ingress Controller to manage and route traffic into your Kubernetes cluster using NetScaler ADCs (NetScaler CPX, BLX, VPX, or MPX). Using NetScaler Ingress Controller, you can configure NetScaler CPX, BLX, VPX, or MPX according to the Ingress rules and integrate your NetScaler ADCs with the Kubernetes environment.
NetScaler Kubernetes Gateway Controller	This container is an implementation of the Kubernetes Gateway API to provide a flexible, extensible, and role-oriented approach for

© 1997–2026 Citrix Systems, Inc. All rights reserved.

COMPONENT	DESCRIPTION
	managing external access to Kubernetes services using NetScaler ADCs (NetScaler CPX, BLX, VPX, or MPX). By using NetScaler's advanced traffic management and security capabilities through the standard Kubernetes Gateway API, you can achieve secure, scalable, and high-performing application delivery in cloud-native environments.
NetScaler Observability Exporter	NetScaler Observability Exporter is a container which collects metrics and transactions from NetScaler ADCs and transforms them to suitable formats (such as JSON, AVRO) for supported endpoints. You can export the data collected by NetScaler Observability Exporter to the desired endpoint. By analyzing the data exported to the endpoint, you can get valuable insights at a microservices level for applications proxied by NetScaler ADCs.
NetScaler xDS adapter	NetScaler xDS adapter is a container for integrating NetScaler with service mesh control plane implementations based on xDS APIs (Istio, Consul, and so on). It communicates with the service mesh control plane and listens for updates by acting as a gRPC client to the control plane API server. Based on the updates from the control plane, the NetScaler xDS-Adaptor generates the equivalent NetScaler configuration.
NetScaler CPX	NetScaler CPX is a container-based application delivery controller that can be provisioned on a Docker host. NetScaler CPX enables customers to leverage Docker engine capabilities and use NetScaler load balancing and traffic management features for container-based applications. You can deploy one or more NetScaler CPX instances as standalone instances on a Docker host.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

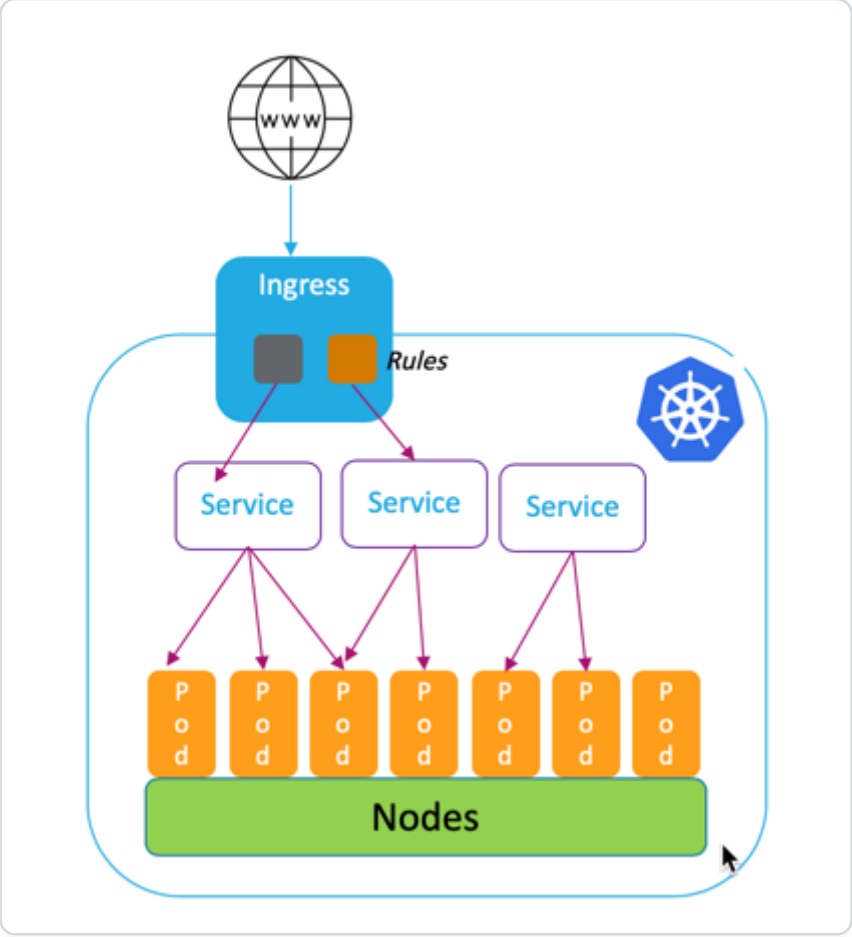
Kubernetes Ingress solution

This topic provides an overview of the Kubernetes Ingress solution provided by NetScaler® and explains the benefits.

What is Kubernetes Ingress?

When you are running an application inside a Kubernetes cluster, you need to provide a way for external users to access the applications from outside the Kubernetes cluster. Kubernetes provides an object called Ingress that provides the most effective way to expose multiple services using a stable IP address. A Kubernetes ingress object is always associated with one or more services and acts as a single-entry point for external users to access services running inside the cluster.

The following diagram explains how Kubernetes Ingress works.



Kubernetes Ingress implementation consists of the following components:

- **Ingress resource**. An Ingress resource allows you to define rules for accessing the applications from outside of the cluster.
- **Ingress controller**. An Ingress controller is an application deployed inside the cluster that interprets rules defined in the Ingress. Ingress controller converts the Ingress rules into

© 1997–2026 Citrix Systems, Inc. All rights reserved.

configuration instructions for a load balancing application integrated with the cluster. The load balancer can be a software application running inside your Kubernetes cluster or a hardware appliance running outside the cluster.

- **Ingress device**. An Ingress device is a load balancing application like NetScaler CPX, VPX, or MPX which performs load balancing according to the configuration instructions provided by the Ingress controller.

What is the Kubernetes Ingress solution from NetScaler?

In this solution, NetScaler provides an implementation of Kubernetes Ingress controller to manage and route traffic into your Kubernetes cluster using NetScaler ADCs (NetScaler CPX, VPX, or MPX). The NetScaler Ingress Controller integrates NetScaler ADCs with your Kubernetes environment and configures NetScaler CPX, VPX, or MPX according to the Ingress rules.

Standard Kubernetes Ingress solutions provide load balancing only at layer 7 (HTTP or HTTPS traffic). Some times, you need to expose many legacy applications which rely on TCP or UDP or applications and need a way to load balance those applications. NetScaler Ingress Controller solution provides TCP, TCP-SSL, and UDP traffic support apart from the standard HTTP or HTTPS Ingress. Also, it works seamlessly across multiple clouds or on-premises data centers.

NetScaler provides enterprise-grade traffic management policies like rewrite and responder policies for efficiently load balancing traffic at layer 7. However, Kubernetes Ingress lacks such enterprise-grade traffic management policies. With the Kubernetes Ingress solution from NetScaler, you can apply rewrite and responder policies for application traffic in a Kubernetes environment using CRDs provided by NetScaler.

The Kubernetes Ingress solution from NetScaler also supports automated canary deployment for your CI/CD application pipeline. In this solution, NetScaler is integrated with the Spinnaker platform and acts as a source for providing accurate metrics for analyzing Canary deployment using Kayenta. After analyzing the metrics, Kayenta generates an aggregate score for the canary and decides to promote or fail the Canary version. You can also regulate traffic distribution to the Canary version using the NetScaler policy infrastructure.

The following table summarizes the benefits offered by the Ingress solution from NetScaler over Kubernetes Ingress.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

FEATURES	KUBERNETES INGRESS	INGRESS SOLUTION FROM NETSCALER
HTTP and HTTPs support	Yes	Yes
URL routing	Yes	Yes
TLS	Yes	Yes
Load balancing	Yes	Yes
TCP, TCP-SSL	No	Yes
UDP	No	Yes
HTTP/2	Yes	Yes
Automated canary deployment support with CI/CD tools	No	Yes
Support for applying NetScaler rewrite and responder policies	No	Yes
Authentication (Open Authorization (OAuth), mutual TLS (mTLS))	No	Yes
Support for applying NetScaler Rate Limiting policies	No	Yes

Deployment options for Kubernetes Ingress solution

Kubernetes Ingress solution from NetScaler provides you flexible architecture depending on how you want to manage your NetScaler ADCs and Kubernetes environment.

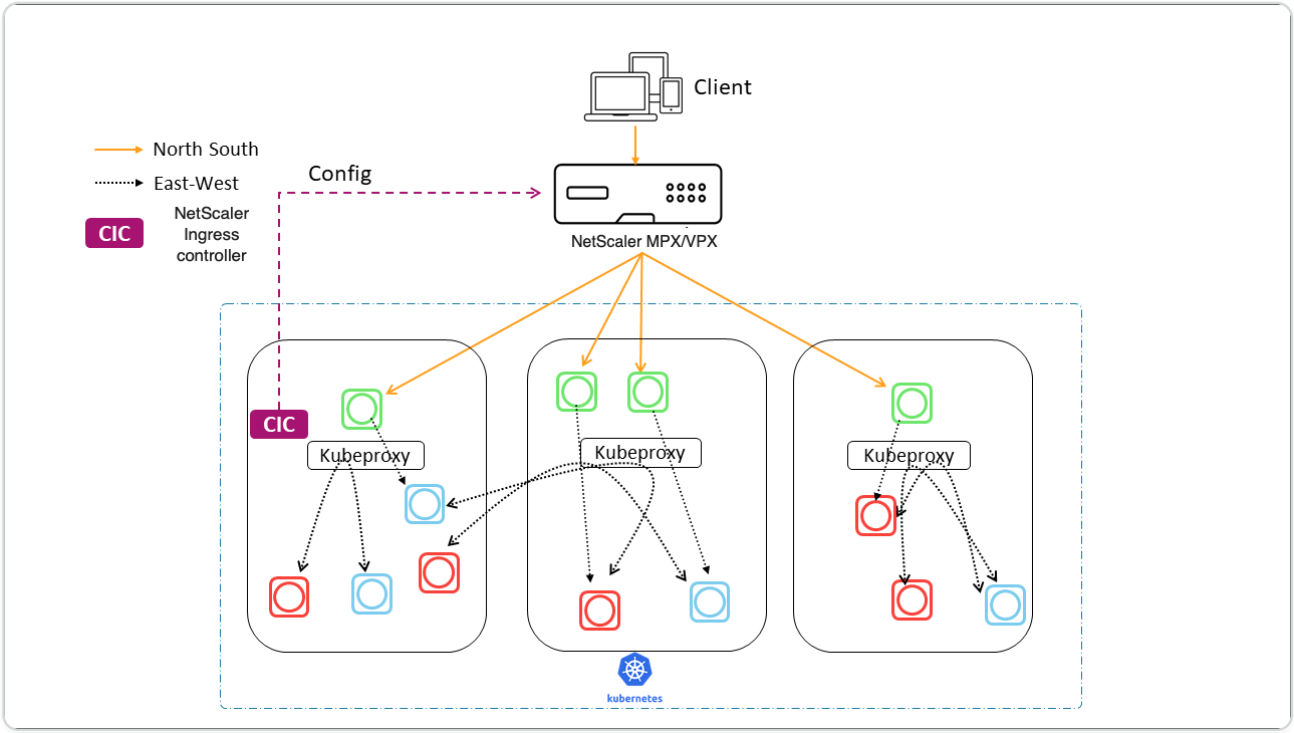
Unified Ingress (single-tier)

In a unified Ingress (single-tier) architecture, a NetScaler MPX or VPX device deployed outside the Kubernetes cluster is integrated with the Kubernetes environment using the NetScaler Ingress

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Controller. The NetScaler Ingress Controller is deployed as a pod in the Kubernetes cluster and automates the configuration of NetScaler ADCs based on changes to the microservices or the Ingress resources. The NetScaler device performs functions like load balancing, TLS termination, and HTTP or TCP protocol optimizations on inbound traffic and then routes the traffic to the correct microservice within a Kubernetes cluster. This architecture suits best in scenarios where the same team manages the Kubernetes platform and other networking infrastructure including application delivery controllers (ADCs).

The following diagram shows a deployment using the unified Ingress architecture.



A unified Ingress solution provides the following key benefits:

- Provides a way to extend the capabilities of your existing NetScaler infrastructure to the Kubernetes environment
- Enables you to apply traffic management policies for inbound traffic
- Provides a simplified architecture suitable for network-savvy DevOps teams
- Supports multitenancy

Dual-tier Ingress

In a dual-tier architecture, NetScaler (MPX or VPX) deployed outside the Kubernetes cluster acts at tier 1 and load balances North-South traffic to NetScaler CPXs running inside the cluster.

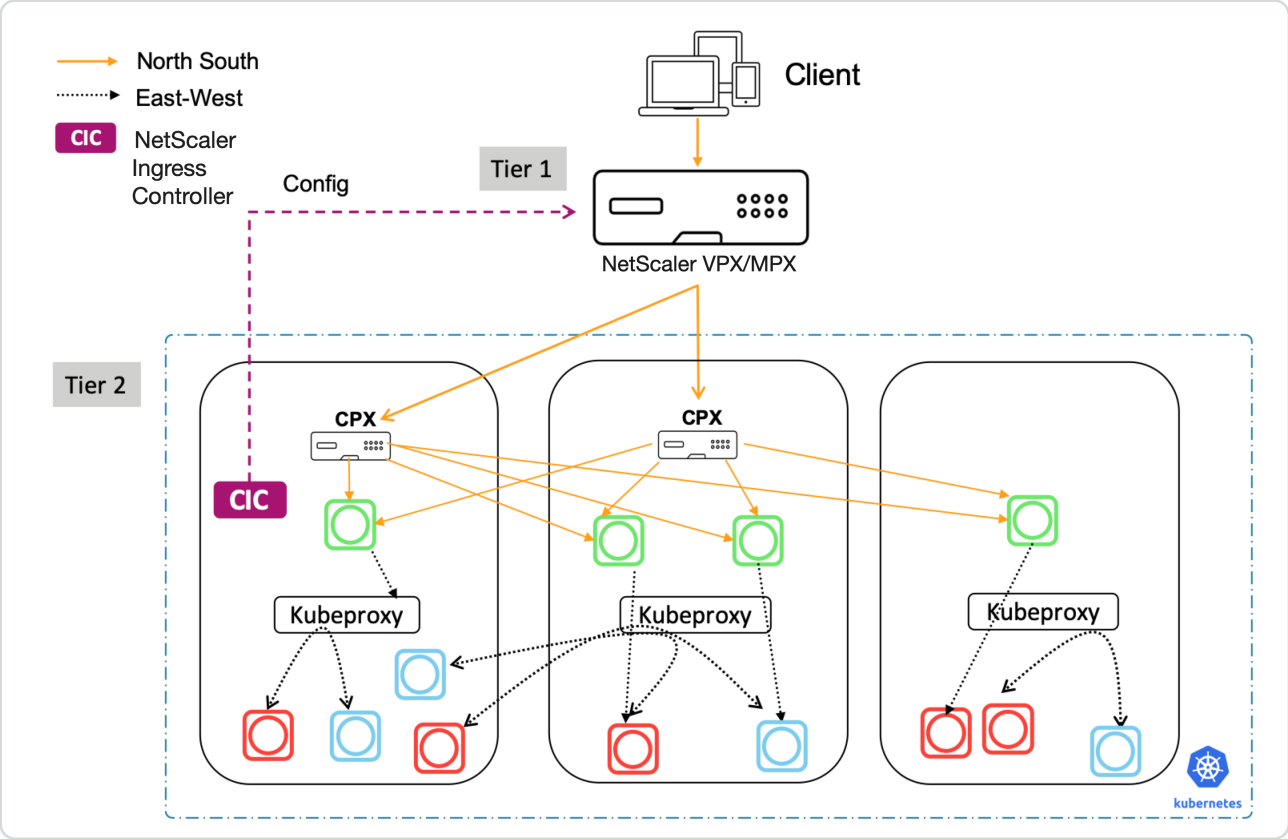
© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler CPX acts at tier 2 and performs load balancing for microservices inside the Kubernetes cluster.

In scenarios where separate teams manage the Kubernetes platform and the network infrastructure, the dual-tier architecture is most suitable.

Networking teams use tier 1 NetScaler for use cases such as GSLB, TLS termination on the hardware platform, and TCP load balancing. Kubernetes platform teams can use tier 2 NetScaler (CPX) for Layer 7 (HTTP/HTTPS) load balancing, mutual TLS, and observability or monitoring of microservices. The tier 2 NetScaler (CPX) can have a different software release version than the tier 1 NetScaler to accommodate newly available capabilities.

The following diagram shows a deployment with dual-tier architecture.



A dual-tier Ingress provides the following key benefits:

- Ensures high velocity of application development for developers or platform teams
- Enables applying developer driven traffic management policies for microservices inside the Kubernetes cluster
- Enables cloud scale and multitenancy

For more information, see the NetScaler Ingress Controller documentation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler® Kubernetes Gateway Controller

As organizations increasingly adopt Kubernetes for deploying and managing their applications, the need for robust and scalable solutions for handling external traffic becomes paramount. NetScaler, a leading Application Delivery Controller™ (ADC), provides a powerful and feature-rich solution, seamlessly integrating with Kubernetes by implementing the Kubernetes Gateway API.

For detailed information on NetScaler Kubernetes Gateway Controller, its key features, benefits, and how it enables secure and efficient application delivery in Kubernetes environments, see NetScaler Kubernetes Gateway Controller documentation.

Service mesh

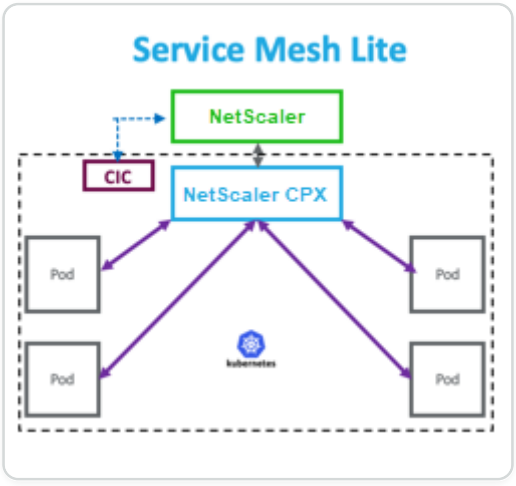
A service mesh is an infrastructure layer for handling service-to-service communication for cloud-native applications using APIs. It provides a way to connect, secure, and monitor your microservices. NetScaler® provides two solutions to meet your service mesh requirements:

- Service mesh lite
- Service mesh (NetScaler integration with Istio)

Service mesh lite

A full-fledged service-mesh implementation is complex and requires a steep learning curve. If you are looking for a simplified implementation of a service mesh with similar benefits, NetScaler offers a solution called service mesh lite with lesser complexity. In this solution, a NetScaler CPX runs as a centralized load balancer in the Kubernetes cluster and load balances East-West traffic among microservices. NetScaler CPX enforces policies for inbound and inter-container traffic.

The following diagram shows a service mesh lite architecture.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

For information, see the service mesh lite documentation.

Service mesh (NetScaler integration with Istio)

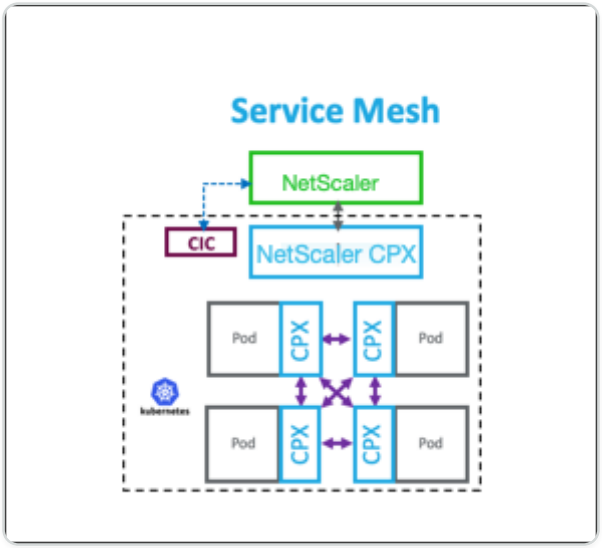
NetScaler provides a service mesh solution by integrating NetScaler with Istio. Istio, an open source and platform-independent service mesh, is one of the most popular service mesh implementations. By integrating NetScaler with Istio, you can take advantage of the NetScaler features to secure and optimize the traffic for applications in the service mesh.

NetScaler can be integrated with Istio in the following ways:

- NetScaler MPX, VPX, or CPX as an Istio Ingress Gateway to the service mesh to expose traffic to the Kubernetes cluster.
- NetScaler CPX as a sidecar proxy with application containers in the service mesh to control communication between applications.

You can use either integration independently or you can combine both ways to have a unified data plane solution.

The following diagram shows a service mesh architecture.



Service mesh is ideal for highly secure applications and also offers the following benefits.

- Offers fine-grained (modularized) traffic management per container
- Ensures richer observability, analytics, and security (Mutual TLS) due to sidecar implementation
- Enables automated canary deployment for each container with embedded NetScaler CPX
- Supports cloud portability

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Allows offloading of some of the functions performed by applications to the sidecar
- Provides lower sidecar latency
- Provides integrations with open-source tools
- Offers scalability

For more information, see the NetScaler integration with Istio documentation.

Solutions for observability

In a microservices based architecture, visibility into service to service communications is critical to build an efficient and resilient architecture. Traditional ways for logging and monitoring is not capable of addressing the challenges of a microservices architecture. Observability solutions from Citrix® provide you the ability to see what is happening when your services interact with each other and get meaningful insights about your system.

NetScaler® provides the following solutions to address the observability needs of your microservices architecture:

- NetScaler Console service graph and analytics
- NetScaler Observability Exporter

NetScaler Console service graph and analytics

NetScaler Application Delivery Management (ADM) is a centralized management solution that provides enterprise-wide visibility and automation for management jobs that need to be run across multiple instances.

In a microservice architecture, troubleshooting is challenging because a single end-user request may span across multiple microservices.

NetScaler Console service graph and analytics provides visibility into interactions between microservices and helps to identify and fix issues based on various metrics such as latency and HTTP errors.

NetScaler Console also provides advanced analytics based on metrics and transaction logs collected from NetScaler.

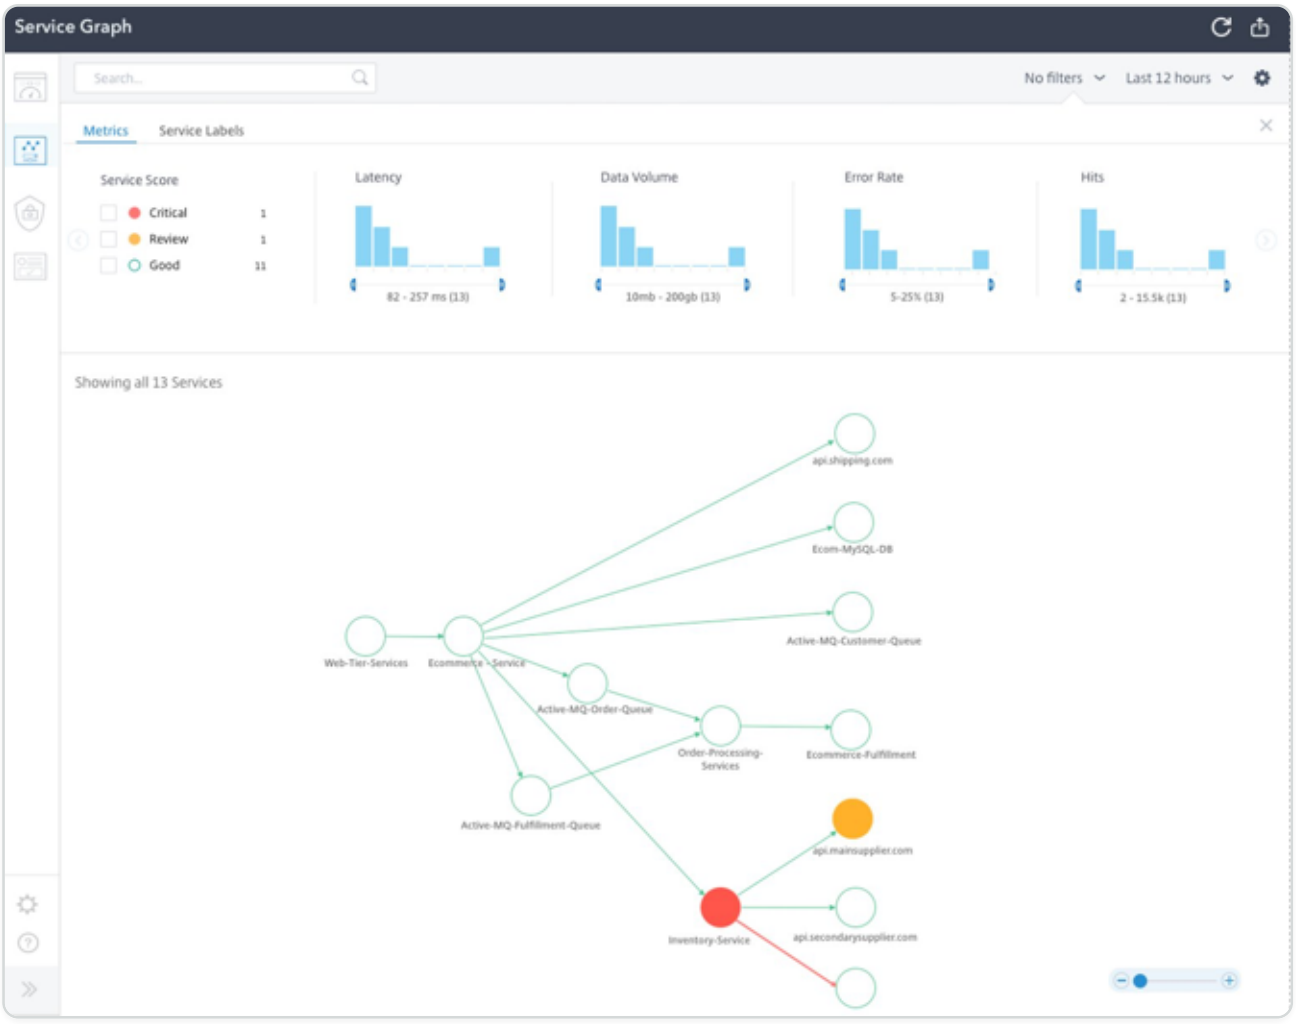
NetScaler Console solution provides the following benefits:

- Provides a single pane of glass for applications across containers, on-premises, or cloud

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Provides better observability and faster troubleshooting for microservices
- Supports Canary deployment

The following diagram shows a sample service graph for an application which contains multiple microservices.



For more information on how to set up NetScaler Console service graph and analytics, see the Service graph documentation.

NetScaler Observability Exporter

NetScaler Observability Exporter is a container which collects metrics and transactions from NetScalers and transforms them to suitable formats (such as JSON, AVRO) for supported endpoints. You can export the data collected by NetScaler Observability Exporter to the desired endpoint. By analyzing the data, you can get valuable insights at a microservices level for applications proxied by NetScalers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Distributed tracing support

Distributed tracers allow you to visualize the data flow between your microservices and helps to identify the bottlenecks in your microservices architecture. OpenTracing is a specification and standard set of APIs for designing and implementing distributed tracing.

NetScaler Observability Exporter implements distributed tracing for NetScaler and currently supports Zipkin as the distributed tracer.

You can enhance the trace analysis by using Elasticsearch and Kibana with Zipkin. Elasticsearch provides long-term retention of the trace data. Kibana allows you to get much deeper insight into the data by providing a tool to explore, and visualize log messages.

Transaction collection and streaming support

NetScaler Observability Exporter supports collecting transactions and streaming them to endpoints. Currently, NetScaler Observability Exporter supports Elasticsearch and Kafka as transaction endpoints.

For more information, see the NetScaler Observability Exporter documentation.

Enable analytics using annotations in the NetScaler Ingress Controller YAML file

You can enable analytics using the analytics profile which is defined as a smart annotation in Ingress or service of type LoadBalancer configuration. You can define the specific parameters you need to monitor by specifying them in the Ingress or service configuration of the application. For more information about enabling analytics using annotations, see Analytics using annotations.

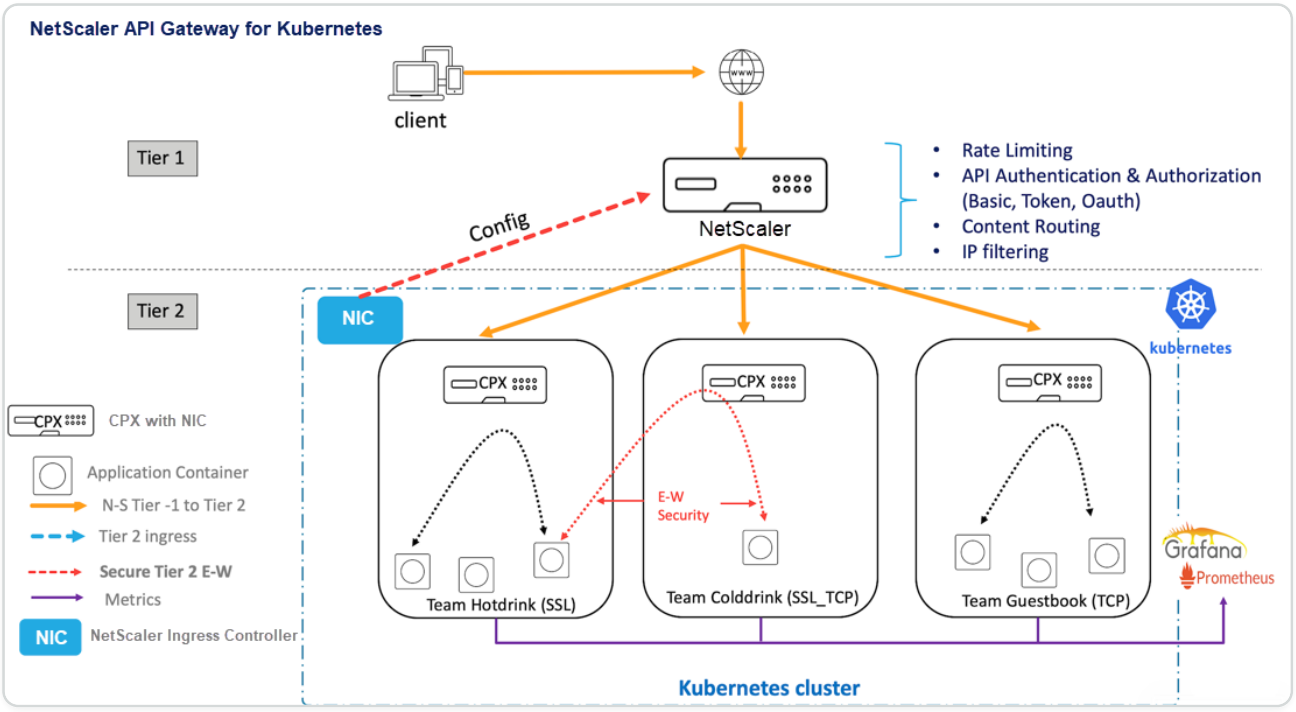
API gateway for Kubernetes

An API gateway acts as the single entry point for your APIs and ensures secure and reliable access to multiple APIs and microservices in your system.

NetScaler® provides an enterprise grade API gateway for North-South API traffic into the Kubernetes cluster. The API gateway integrates with Kubernetes through the NetScaler Ingress Controller and the NetScaler (NetScaler MPX, VPX, or CPX) deployed as the Ingress Gateway for on-premises or cloud deployments.

The following diagram shows a dual-tier topology for the API gateway.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Using the API gateway offered by Citrix®, you can perform the following functionalities:

- Enforce authentication policies
- Rate limit access to services
- Advanced content routing
- Flexible and comprehensive transformation of HTTP transactions using the rewrite and responder policies
- Enforce web application firewall policies

How does the API gateway work

The API gateway is built on top of the NetScaler Ingress Gateway and uses Kubernetes API extensions such as custom resource definitions (CRDs). Using CRDs, you can automatically configure the NetScaler and API gateway in the same instance.

NetScaler provides the following CRDs for the API gateway:

- Auth CRD
- Rate limit CRD
- Content routing CRD
- Rewrite and responder CRD
- WAF CRD

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Key benefits of using the API gateway

Following are the key benefits of the API gateway offered by Citrix:

- Uses the advanced traffic management and comprehensive security features of NetScaler.
- Optimizes your deployments by consolidating multiple network functions into a single component of the NetScaler Ingress Gateway.
- Reduces the operational complexity and cost involved in deploying multiple components.
- Ensures better performance for your application traffic by reducing multiple hops of TCP or TLS decryption while using separate components.
- Simplifies deploy and integrate in your Kubernetes environments either by directly using YAMLs or helm charts.

Deploying the API gateway

For more information on how to configure the API gateway features using CRDs, see the NetScaler Ingress Controller documentation:

- Authentication
- Rate limiting
- Advanced content routing
- Rewrite and responder policies
- Web application firewall policies

Use NetScaler Console to troubleshoot NetScaler cloud native networking

Overview

This document provides information about how you can use NetScaler Console to deliver and monitor Kubernetes microservice applications. You also dive into using the CLI, service graphs, and tracing to allow the platform and SRE teams to troubleshoot.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Application performance and latency overview

TLS encryption

TLS is an encryption protocol designed to secure Internet communications. A TLS handshake is the process that begins a communication session that uses TLS encryption. During a TLS handshake, the two communicating sides exchange messages to acknowledge each other, verify each other, establish the encryption algorithms they use, and agree on session keys. TLS handshakes are a foundational part of how HTTPS works.

TLS vs SSL handshakes

SSL (Secure Sockets Layer), was the original encryption protocol developed for HTTP. TLS (Transport Layer Security) replaced SSL some time ago. SSL handshakes are now called TLS handshakes, although the "SSL" name is still in wide use.

When does a TLS handshake occur?

A TLS handshake takes place whenever a user navigates to a website over HTTPS and the browser first begins to query the website's origin server. A TLS handshake also happens whenever any other communications use HTTPS, including API calls and DNS over HTTPS queries.

TLS handshakes occur after a TCP connection has been opened via a TCP handshake.

What happens during a TLS handshake?

- During a TLS handshake, the client and server together do the following:
    - Specify which version of TLS (TLS 1.0, 1.2, 1.3, and so forth) they use.
    - Decide on which cipher suites (see the following section) they use.
    - Authenticate the identity of the server via the server’s public key and the SSL certificate authority’s digital signature.
    - Generate session keys to use symmetric encryption after the handshake is complete.

What are the steps of a TLS handshake?

- TLS handshakes are a series of datagrams, or messages, exchanged by a client and a server. A TLS handshake involves multiple steps, as the client and server exchange the information necessary for completing the handshake and making further conversation possible.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The exact steps within a TLS handshake vary depending upon the kind of key exchange algorithm used and the cipher suites supported by both sides. The RSA key exchange algorithm is used most often. It goes as follows:

1. The 'client hello' message: The client initiates the handshake by sending a "hello" message to the server. The message includes which TLS version the client supports, the cipher suites supported, and a string of random bytes known as the "client random."
2. The 'server hello' message: In reply to the client hello message, the server sends a message containing the server's SSL certificate, the server's chosen cipher suite, and the "server random," another random string of bytes that's generated by the server.
3. Authentication: The client verifies the server's SSL certificate with the certificate authority that issued it. This confirms that the server is who it says it is, and that the client is interacting with the actual owner of the domain.
4. The premaster secret: The client sends one more random string of bytes, the "premaster secret." The premaster secret is encrypted with the public key and can only be decrypted with the private key by the server. (The client gets the public key from the server's SSL certificate.)
5. Private key used: The server decrypts the premaster secret.
6. Session keys created: Both client and server generate session keys from the client random, the server random, and the premaster secret. They should arrive at the same results.
7. Client is ready: The client sends a "finished" message that is encrypted with a session key.
8. Server is ready: The server sends a "finished" message encrypted with a session key.
9. Secure symmetric encryption achieved: The handshake is completed, and communication continues using the session keys.

All TLS handshakes use asymmetric encryption (the public and private key), but not all use the private key in the process of generating session keys. For instance, an ephemeral Diffie-Hellman handshake proceeds as follows:

1. Client hello: The client sends a client hello message with the protocol version, the client random, and a list of cipher suites.
2. Server hello: The server replies with its SSL certificate, its selected cipher suite, and the server random. In contrast to the RSA handshake described in the previous section, in this message the server also includes the following (step 3).
3. Server's digital signature: The server uses its private key to encrypt the client random, the server random, and its DH parameter*. This encrypted data functions as the server's digital

© 1997–2026 Citrix Systems, Inc. All rights reserved.

signature, establishing that the server has the private key that matches with the public key from the SSL certificate.

4. Digital signature confirmed: The client decrypts the server's digital signature with the public key, verifying that the server controls the private key and is who it says it is. Client DH parameter: The client sends its DH parameter to the server.
5. Client and server calculate the premaster secret: Instead of the client generating the premaster secret and sending it to the server, as in an RSA handshake, the client and the server use the DH parameters they exchanged to calculate a matching premaster secret separately.
6. Session keys created: Now, the client and server calculate session keys from the premaster secret, client random, and server random, just like in an RSA handshake.

    - Client is ready: Same as an RSA handshake
    - Server is ready
    - Secure symmetric encryption achieved

    *DH parameter: DH stands for Diffie-Hellman. The Diffie-Hellman algorithm uses exponential calculations to arrive at the same premaster secret. The server and client each provide a parameter for the calculation, and when combined they result in a different calculation on each side, with results that are equal.

To read more about the contrast between ephemeral Diffie-Hellman handshakes and other kinds of handshakes, and how they achieve forward secrecy, see this TLS Protocol Documentation.

What is a cipher suite?

- A cipher suite is a set of encryption algorithms for use in establishing a secure communications connection. (An encryption algorithm is a set of mathematical operations performed on data for making the data appear random.) There are various cipher suites in wide use, and an essential part of the TLS handshake is agreeing upon which cipher suite is used for that handshake.

To get started, see Reference: TLS Protocol Documentation.

NetScaler® Application Delivery Management SSL dashboard

NetScaler Application Delivery Management (ADM) now streamlines every aspect of certificate management for you. Through a single console, you can establish automated policies to ensure the right issuer, key strength, and correct algorithms, while keeping close tabs on certificates that are unused or soon to expire. To begin using NetScaler Console SSL dashboard and its

© 1997–2026 Citrix Systems, Inc. All rights reserved.

functionalities, you must understand what an SSL certificate is and how you can use NetScaler Console to track your SSL certificates.

A Secure Socket Layer (SSL) certificate, which is a part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the Citrix® Application Delivery Controller™ (ADC) appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

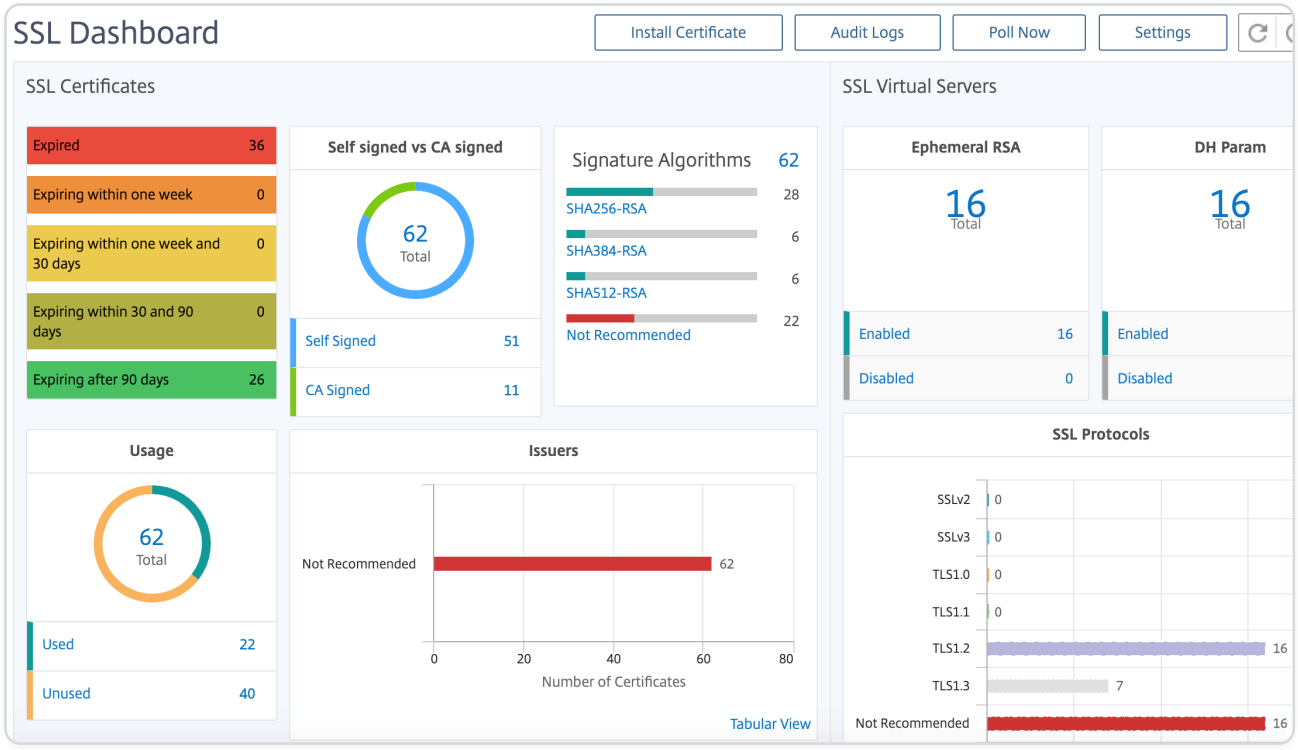
- From an authorized certificate authority (CA)
- By generating a new SSL certificate and key on the NetScaler appliance

NetScaler Console provides a centralized view of SSL certificates installed across all managed NetScaler instances. On the SSL Dashboard, you can view graphs that help you track certificate issuers, key strengths, signature algorithms, expired or unused certificates and so on. You can also see the distribution of SSL protocols that are running on your virtual servers and the keys that are enabled on them.

You can also set up notifications to inform you when certificates are about to expire and include information about which NetScaler instances use those certificates.

You can link a NetScaler instance’s certificates to a CA certificate. However, make sure that the certificates that you link to the same CA certificate have the same source and the same issuer. After you have linked the certificates to a CA certificate, you can unlink them.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



To get started, see the SSL Dashboard Documentation.

Third party integrations

Application latency is measured in milliseconds, and it can indicate one of two things depending on the metric used. The more common way of measuring latency is called “round-trip time” (or RTT). RTT calculates the time it takes for a data packet to travel from one point to another on the network, and for a response to be sent back to the source. The other measurement is called “time to first byte” (or TTFB), which records the time it takes from the moment a packet departs a point on the network to the moment it arrives at its destination. RTT is more commonly used to measure latency because it can be run from a single point on the network and does not require data collection software to be installed on the destination point (as TTFB does).

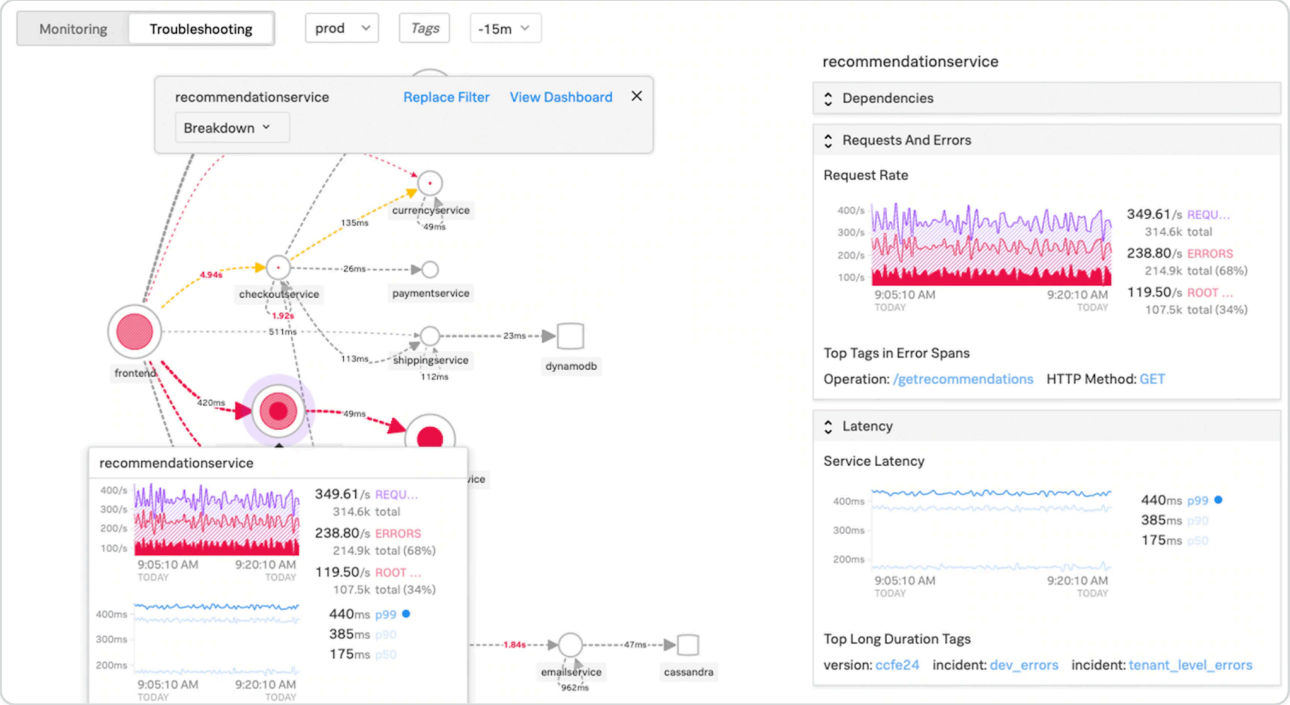
By monitoring your Application bandwidth usage and performance in real time, the ADM service makes it easy to identify issues and to preemptively address potential problems before they manifest and affect users on your network. This flow-based solution tracks usage by interface, application, and conversation, giving you detailed information about activity across your network.

Using Splunk tools

Infrastructure and application performance are interdependent. To see the full picture, SignalFx provides seamless correlation between cloud infrastructure and the microservices running on top of it. If your application acts out because of memory leakage, a noisy neighbor container or any

© 1997–2026 Citrix Systems, Inc. All rights reserved.

other infrastructure-related issue, SignalFx lets you know. To complete the picture, in-context access to Splunk logs and events enable deeper troubleshooting and root cause analysis.



For more information on SignalFx Microservices APM and troubleshooting with Splunk, view Splunk for DevOps information.

MongoDB support

MongoDB stores data in flexible, JSON-like documents. Meaning fields can vary from document to document and data structure can be changed over time.

The document model maps to the objects in your application code, making data easy to work with.

On-demand queries, indexing, and real time aggregation provide powerful ways to access and analyze your data.

MongoDB is a distributed database at its core, so high availability, horizontal scaling, and geographic distribution are built in and easy to use.

MongoDB is designed to meet the demands of modern apps with a technology foundation that enables you through:

- The document data model – presenting you the best way to work with data.
- A distributed systems design – allowing you to intelligently put data where you want it.
- A unified experience that gives you the freedom to run anywhere – allowing you to future-proof your work and eliminate vendor lock-in.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

With these capabilities, you can build an Intelligent Operational Data Platform, underpinned by MongoDB. For more information, see MongoDB Documentation.

How to load balance Ingress traffic to TCP or UDP based application

In a Kubernetes environment, an Ingress is an object that allows access to the Kubernetes services from outside the Kubernetes cluster. Standard Kubernetes Ingress resources assume that all the traffic is HTTP-based and does not cater to non-HTTP based protocols such as, TCP, TCP-SSL, and UDP. Hence, critical applications based on L7 protocols such as DNS, FTP, LDAP, cannot be exposed using standard Kubernetes Ingress.

The standard Kubernetes solution is to create a service of type LoadBalancer. See Service Type LoadBalancer in NetScaler for more information.

The second option is to annotate the ingress object. NetScaler Ingress Controller enables you to load balance TCP or UDP based Ingress traffic. It provides the following annotations that you can use in your Kubernetes Ingress resource definition to load balance the TCP or UDP based Ingress traffic:

- ingress.citrix.com/insecure-service-type: The annotation enables L4 load balancing with TCP, UDP, or ANY as protocol for NetScaler.
- ingress.citrix.com/insecure-port: The annotation configures the TCP port. The annotation is helpful when micro service access is required on a non-standard port. By default, port 80 is configured.

For more information, see How to load balance Ingress traffic to TCP or UDP based application.

Monitor and improve the performance of your TCP or UDP based applications

Application developers can closely monitor the health of TCP or UDP based applications through rich monitors (such as TCP-ECV, UDP-ECV) in NetScaler. The ECV (extended content validation) monitors help in checking whether the application is returning expected content or not.

Also, the application performance can be improved by using persistence methods such as source IP. You can use these NetScaler features through Smart Annotations in Kubernetes. The following is one such example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
apiVersion: extensions/v1beta1

kind: Ingress

metadata:

    name: mongodb

    annotations:

        ingress.citrix.com/insecure-port: “80”

        ingress.citrix.com/frontend-ip: “192.168.1.1”

        ingress.citrix.com/csvserver: ‘{“l2conn”:”on”}’

        ingress.citrix.com/lbvserver: ‘{“mongodb-svc”:
{“lbmethod”:”SRCIPDESTIPHASH”}}’

        ingress.citrix.com/monitor: ‘{“mongodbsvc”:{“type”:”tcp-ecv”}}’

Spec:

    rules:

    - host: mongodb.beverages.com

      http:

        paths:

        - path: /

          backend:

            serviceName: mongodb-svc

            servicePort: 80
```

NetScaler Application Delivery Management (ADM) Service

NetScaler Console Service provides the following benefits:

- **Agile** – Easy to operate, update, and consume. The service model of NetScaler Console Service is available over the cloud, making it is easy to operate, update, and use the features provided. The frequency of updates, combined with the automated update feature, quickly enhances your NetScaler deployment.
- **Faster time to value** – Quicker business goals achievement. Unlike the traditional on-premises deployment, you can use your NetScaler Console Service with a few clicks. You not only save on installation and configuration time, but also avoid wasting time and resources on potential errors.
- **Multi-Site Management** – Single Pane of Glass for instances across Multi-Site data centers. With the NetScaler Console Service, you can manage and monitor NetScalers that are in various types of deployments. You have one-stop management for NetScalers deployed on-premises and in the cloud.
- **Operational Efficiency** – Optimized and automated way to achieve higher operational productivity. With the NetScaler Console Service, your operational costs are reduced by saving your time, money, and resources on maintaining and upgrading the traditional hardware deployments.

Service graph for Kubernetes applications

Using the service graph for the cloud-native application feature in NetScaler Console, you can:

- Ensure end-to-end application overall performance
- Identify bottlenecks created by the interdependency of different components of your applications
- Gather insights into the dependencies of different components of your applications
- Monitor services within the Kubernetes cluster
- Monitor which service has issues
- Check the factors contributing to performance issues
- View detailed visibility of service HTTP transactions
- Analyze the HTTP, TCP, and SSL metrics

© 1997–2026 Citrix Systems, Inc. All rights reserved.

By visualizing these metrics in NetScaler Console, you can analyze the root cause of issues and take necessary troubleshooting actions faster. Service graph displays your applications in various component services. These services running inside the Kubernetes cluster can communicate with various components within and outside the application.

To get started, see Setting up service graph.

Service graph for 3-tier web applications

Using the service graph feature from the application dashboard, you can view:

- Details on how the application is configured (with content switching virtual server and load balancing virtual server)
    - For GSLB applications, you can view data center, ADC instance, CS, and LB virtual servers
- End-to-end transactions from client to service
- The location from where the client is accessing the application
- The data center name where the client requests are processed and the associated data center NetScaler metrics (only for GSLB applications)
- Metrics details for client, service, and virtual servers
- If the errors are from the client or from the service
- The service status such as **Critical**, **Review**, and **Good**. NetScaler Console displays the service status based on service response time and error count.
    - **Critical (red)** - Indicates when average service response time > 200 ms AND error count > 0
    - **Review (orange)** - Indicates when average service response time > 200 ms OR error count > 0
    - **Good (green)** - Indicates no error and average service response time < 200 ms
- The client status such as **Critical**, **Review**, and **Good**. NetScaler Console displays the client status based on client network latency and error count.
    - **Critical (red)**- Indicates when average client network latency > 200 ms AND error count > 0
    - **Review (orange)** - Indicates when average client network latency > 200 ms OR error count > 0
    - **Good (green)** - Indicates no error and average client network latency < 200 ms

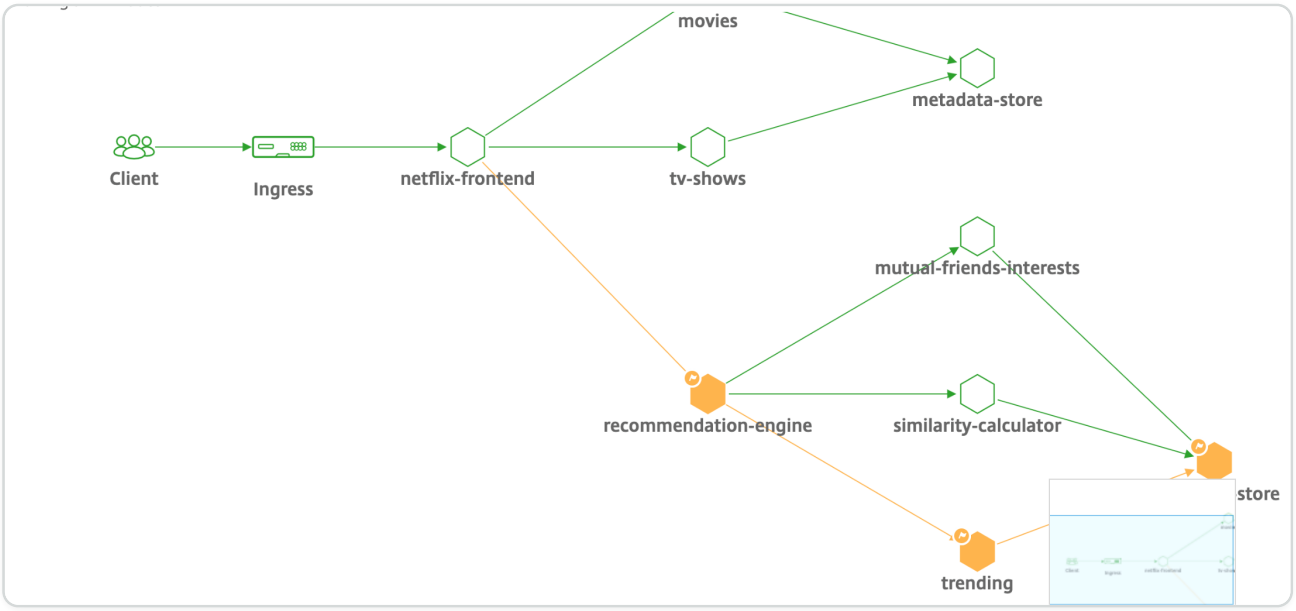
© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The virtual server status such as **Critical**, **Review**, and **Good**. NetScaler Console displays the virtual server status based on the app score.
  - **Critical (red)** - Indicates when app score < 40
  - **Review (orange)** - Indicates when app score is between 40 and 75
  - **Good (green)** - Indicates when app score is > 75

Points to note:

- Only Load Balancing, Content Switching, and GSLB virtual servers are displayed in the service graph.
- If no virtual server is bound to a custom application, the details are not visible in the service graph for the application.
- You can view metrics for clients and services in the service graph only if active transactions occur between virtual servers and web application.
- If no active transactions are available between virtual servers and web application, you can only view details in the service graph based on the configuration data such as load balancing, content switching, GSLB virtual servers, and services.
- Updates in the application configuration might take 10 minutes to reflect in the service graph.

For more information, see Service graph for applications.



To get started, see Service Graph Documentation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Troubleshooting for NetScaler teams

Let's discuss some of the most common attributes for troubleshooting the NetScaler platform and how these troubleshooting techniques apply to the Tier-1 deployments for microservices topologies.

The NetScaler has a command line interface (CLI) that shows commands in real-time and is useful for determining runtime configurations, statics, and policy configuration. This is facilitated via the **“SHOW”** command.

SHOW - perform ADC CLI operations:

```
>Show running config (-summary -fullValues)

 Ability to search (grep command)

>“sh running config | -i grep vserver”

Check the version.

>Show license

  “sh license"
```

Show SSL Statistics

```
>Sh ssl

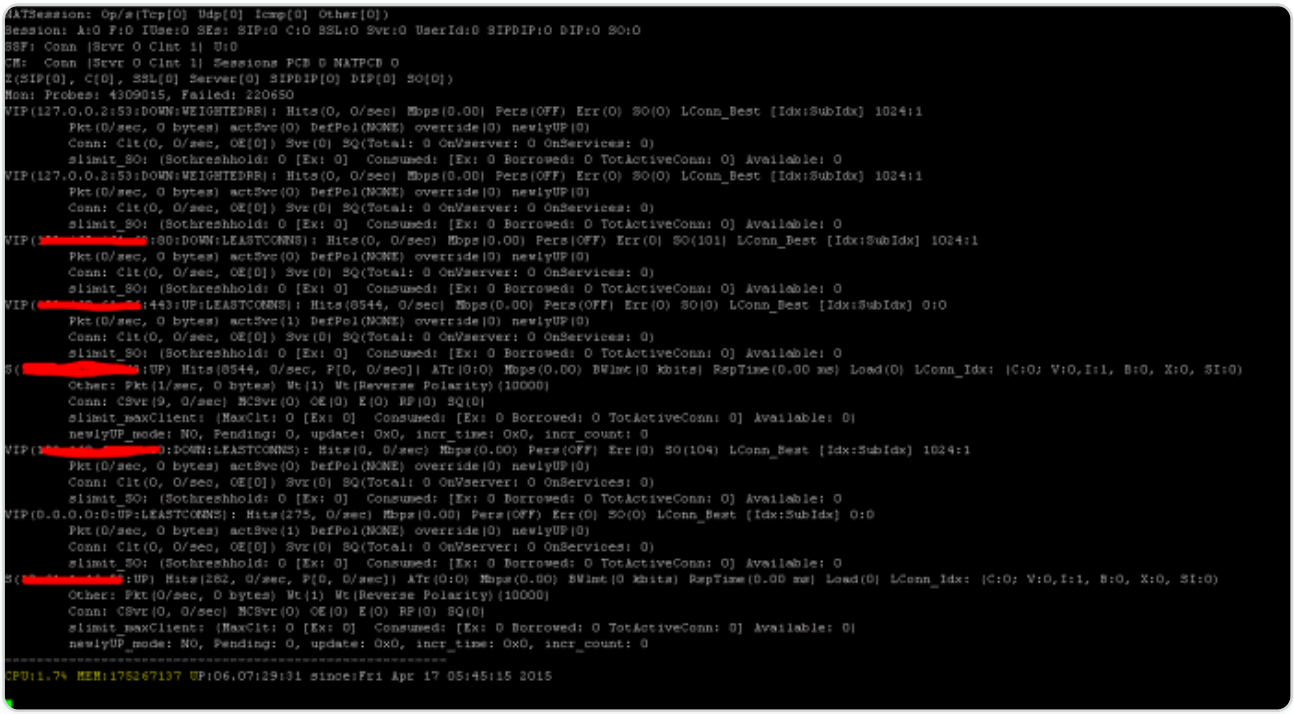
        System

        Frontend

        Backend

        Encryption
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The NetScaler has a command for enumerating statistics for all objects based on a seven (7) second counter interval. This is facilitated via the **“STAT”** command.

Highly granular L3-L7 telemetry by NetScaler

- System Level: CPU and memory utilization of ADC.
- HTTP Protocol: #Requests/Responses, GET/POST split, HTTP errors for N-S and E-W (for service mesh lite only, sidecar soon).
- SSL: #Sessions and #Handshakes for N-S and E-W traffic for service mesh lite only.
- IP Protocol: #Packets receieved/sent, #Bytes received/sent, #Truncated packets, and #IP address lookup.
- NetScaler AAA: #Active Sessions
- Interface: #Total multicast packets, #Total transferred bytes, and #Jumbo packets received/sent.
- Load balancing virtual server and content switching virtual server: #Packets, #Hits, and #Bytes received/sent.

STAT - perform ADC CLI operations:

```
>Statistics

“stat ssl”
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> stat ns

SSL                                      Rate (/s)               Total
```

The NetScaler has a log archive structure that allows for the searching of statistics and counters when troubleshooting specific errors via the **“NSCONMSG”** command.

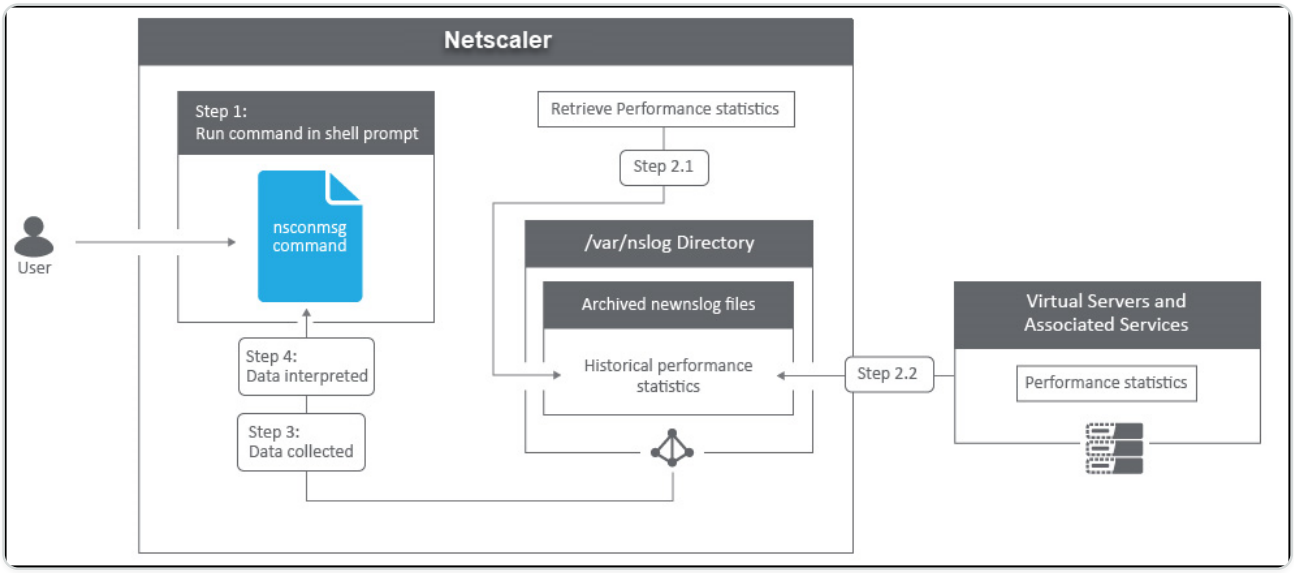
NSCONMSG - main log file (ns data format)

```
Cd/var/nslog

“Mac Moves”

nsconmsg -d current -g nic_err
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Nstcpdump

You can use `nstcpdump` for low-level troubleshooting. `nstcpdump` collects less detailed information than `nstrace`. Open the ADC CLI and type `shell`. You can use filters with `nstcpdump` but cannot use filters specific to ADC resources. The dump output can be viewed directly within the CLI screen.

CTRL + C – Press these keys simultaneously to stop an `nstcpdump`.

`nstcpdump.sh dst host x.x.x.x` – Shows traffic sent to the destination host.

`nstcpdump.sh -n src host x.x.x.x` – Shows traffic from specified host and don't convert IP addresses to names (-n).

`nstcpdump.sh host x.x.x.x` – Shows traffic to and from specified host IP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
root@Netscaler1# nstcpdump.sh -c 10 dst host 192.168.0.242

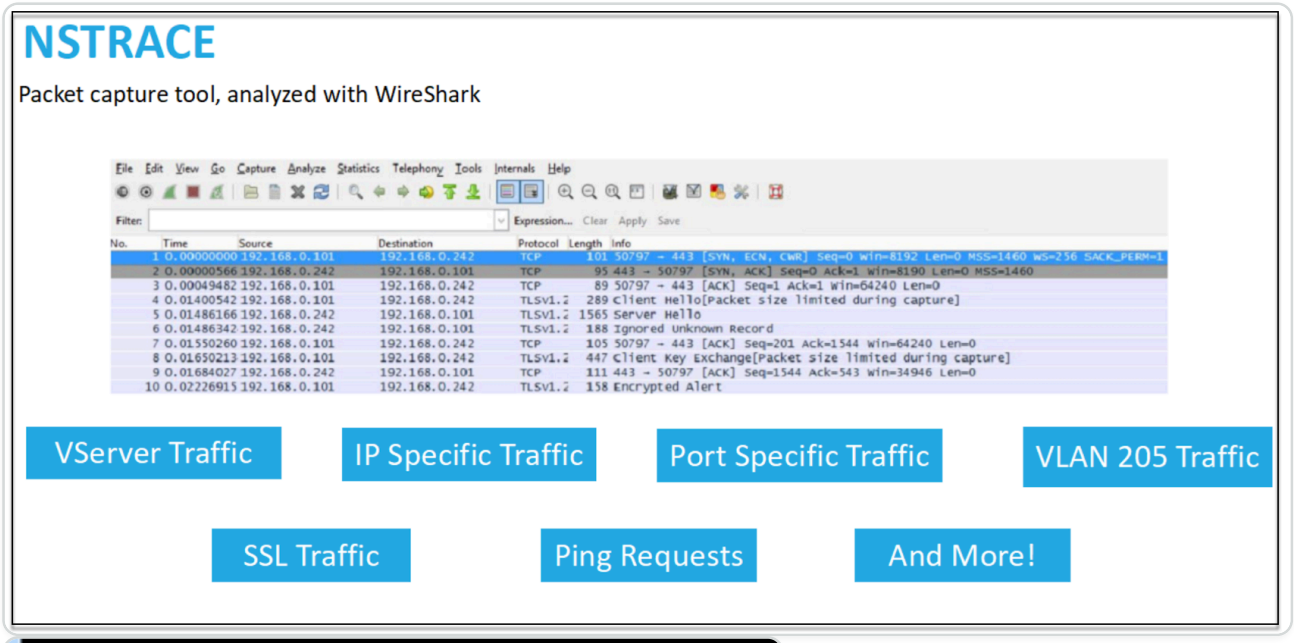
NSTRACE - packet trace file

NSTRACE is a low-level packet debugging tool for troubleshooting networks. It allows you to store capture files that you can analyze further using the analyzer tools. Two common tools are Network Analyzer and Wireshark.



```
> start nstrace -size 0
 Done
> stop nstrace
 Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Once the NSTRACE capture file is created in /var/nstrace on the ADC, you can import the capture file into Wireshark for packet capture and network analysis.

SYSCTL - Detailed ADC info: Description, Model, Platform, CPUs, and so on

```
sysctl -a grep hw.physmem

hw.physmem: 862306304

netscaler.hw_physmem_mb: 822
```

aaad.debug - Open Pipe for authentication debug info

```
process_radius Got RADIUS event
process_radius Received BAD_ACCESS_REJECT for: <username>
process_radius Sending reject.
send_reject_with_code Rejecting with error code 4001.
```

For more information on how to troubleshoot authentication issues through ADC or ADC Gateway with the aaad.debug module, see aaad.debug Support Article.

There is also the ability to obtain performance statistics and event logs directly for the ADC. For more information on this, see ADC Support Document.

Troubleshooting for SRE and platforms teams

Kubernetes traffic flows

North/South:

- North/south traffic is traffic flowing from the user into the cluster, through the ingress.

East/West:

- East/west traffic is traffic flowing around the Kubernetes cluster: service-to-service or service-to-datastore.

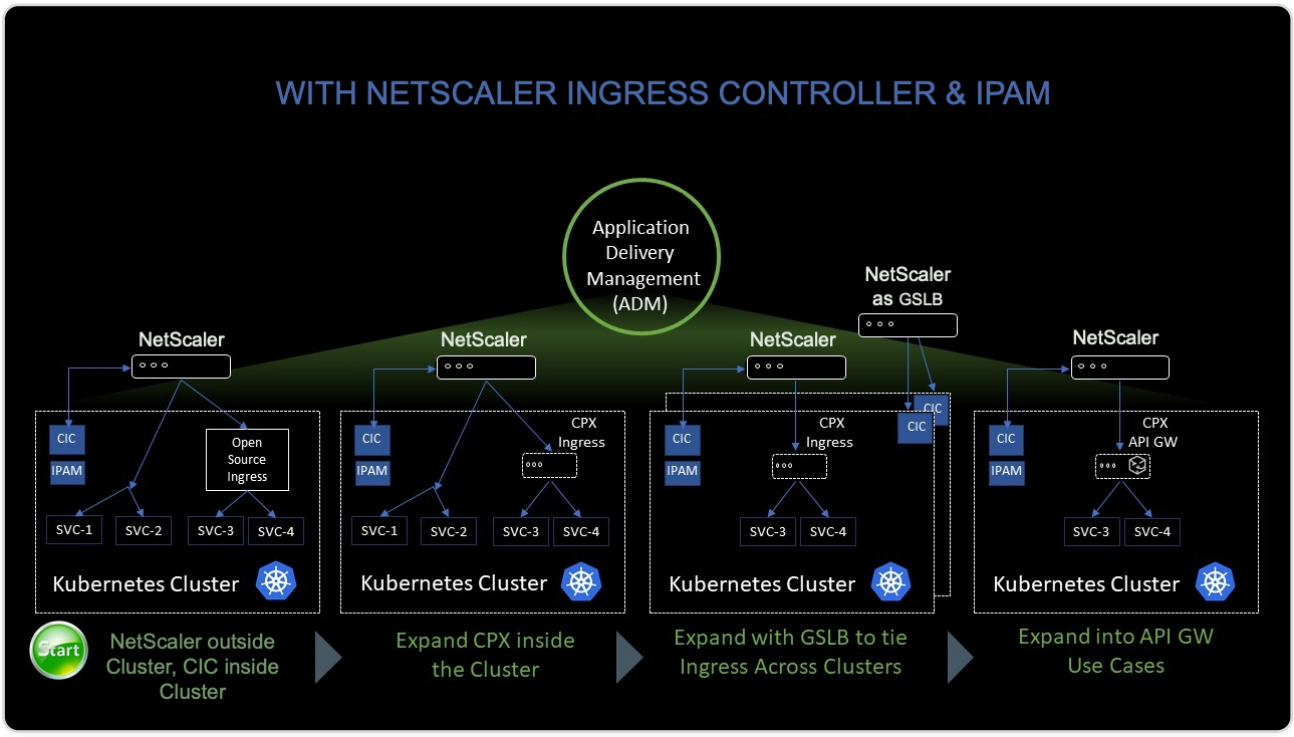
© 1997–2026 Citrix Systems, Inc. All rights reserved.

How NetScaler CPX load balances east-west traffic flow in a Kubernetes environment

After you have deployed the Kubernetes cluster, you must integrate the cluster with ADM by providing the details of the Kubernetes environment in ADM. ADM monitors the changes in Kubernetes resources, such as services, endpoints, and Ingress rules.

When you deploy an NetScaler CPX instance in the Kubernetes cluster, it automatically registers with ADM. As part of the registration process, ADM learns about the CPX instance IP address and the port on which it can reach the instance to configure it by using NITRO REST APIs.

The following figure shows how NetScaler CPX load balances east-west traffic flow in a Kubernetes cluster.



In this example,

Node 1 and Node 2 of the Kubernetes clusters contains instances of a front-end service and a back-end service. When the NetScaler CPX instances are deployed in Node 1 and Node 2, the NetScaler CPX instances are automatically registered with ADM. You must manually integrate the Kubernetes cluster with ADM by configuring the Kubernetes cluster details in ADM.

When a client requests the front-end service, the ingress resource load balances the request between the instances of the front-end service on the two nodes. When an instance of the front-end service needs information from the back-end services in the cluster, it directs the requests to the NetScaler CPX instance in its node. That NetScaler CPX instance load balances the requests between the back-end services in the cluster, providing east-west traffic flow.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ADM service graph for applications

The service graph feature in NetScaler Console enables you to monitor all services in a graphical representation. This feature also provides a detailed analysis and useful metrics. You can view service graphs for:

- Applications configured across all NetScaler instances
- Kubernetes applications
- 3-tier Web applications

To get started, see the details in service graph.

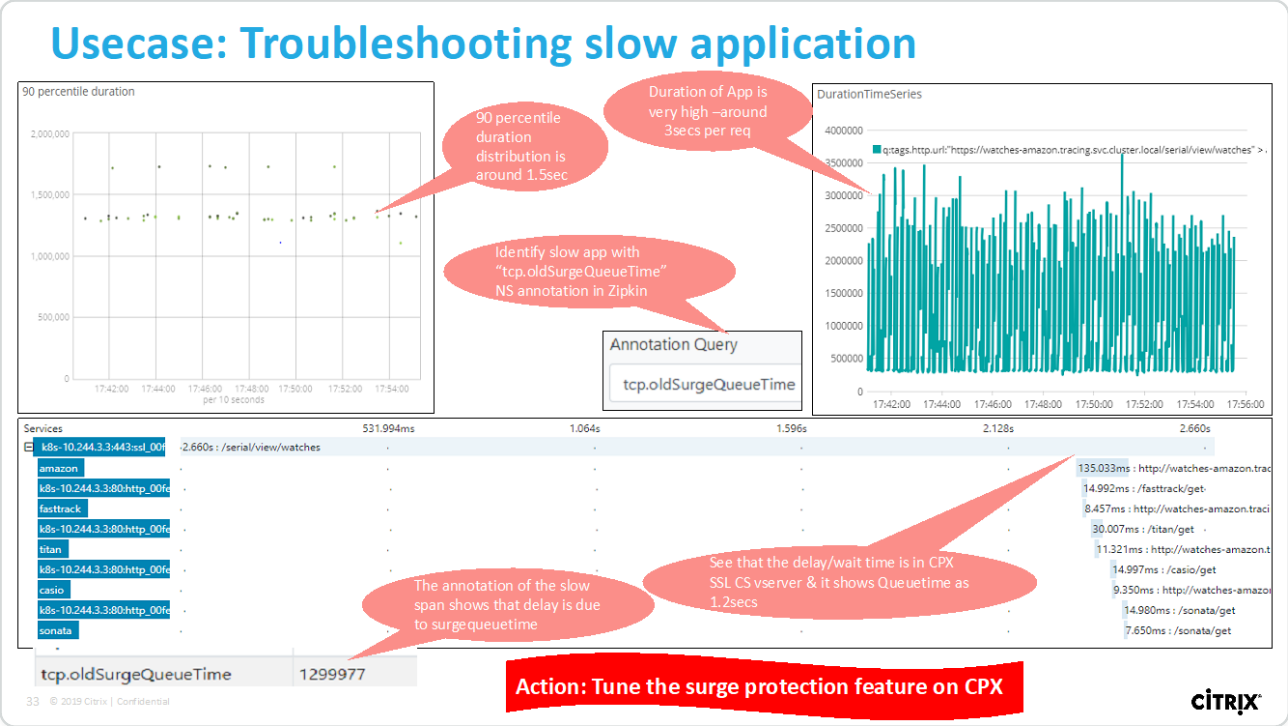
View microservice applications counters

The service graph also displays all microservice applications that belong to the Kubernetes clusters. However, the mouse pointer on a service to view the metrics details.

You can view:

- The service name
- The protocol used by the service such as SSL, HTTP, TCP, SSL over HTTP
- **Hits** – The total number of hits received by the service
- **Service Response Time** – The average response time taken from the service. (Response time = Client RTT + request last byte – request first byte)
- **Errors** – The total errors such as 4xx, 5xx, and so on
- **Data Volume** – The total volume of data processed by the service
- **Namespace** – The namespace of the service
- **Cluster Name** – The cluster name where the service is hosted
- **SSL Server Errors** – The total SSL errors from the service

© 1997–2026 Citrix Systems, Inc. All rights reserved.



These specific counters and transaction logs can be extracted through the NetScaler Observability Exporter (COE) using a range of supported endpoints. For more information on COE, see the following sections.

Exporter for NetScaler stats

This is a simple server that scrapes NetScaler stats and exports them via HTTP to Prometheus. Prometheus can then be added as a data source to Grafana to view the NetScaler stats graphically.

To monitor the stats and counters of NetScaler instances, `citrix-adc-metric-exporter` can be run as a container or script. The exporter collects NetScaler stats such as total hits to a virtual server, HTTP request rate, SSL encryption-decryption rate, and so on from the NetScaler instances and holds them until the Prometheus server pulls the stats and stores them with a timestamp. Grafana can then be pointed to the Prometheus server to fetch the stats, plot them, set alarms, create heat maps, generate tables, and so forth as needed to analyze the NetScaler stats.

Details about setting up the exporter to work in an environment as given in the figure is provided in the following sections. A note on which NetScaler entities/metrics the exporter scrapes by default and how to modify it is also explained.

For more information on Exporter for NetScaler, see the Metrics Exporter GitHub.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ADM service distributed tracing

In the service graph, you can use the distributed tracing view to:

- Analyze the overall service performance.
- Visualize the communication flow between the selected service and its inter-dependent services.
- Identify which service indicates errors and troubleshoot the erroneous service
- View transaction details between the selected service and each interdependent service.

ADM distributed tracing prerequisites

To view the trace information for the service, you must:

- Ensure that an application maintains the following trace headers, while sending any east-west traffic:

  - `x-request-id`
  - `x-b3-traceid`
  - `x-b3-spanid`
  - `x-b3-parentspanid`
  - `x-b3-sampled`
  - `x-b3-flags`
  - `x-ot-span-context`

- Update the CPX YAML file with NS_DISTRIBUTED_TRACING and the value as YES. To get started, see Distributed Tracing.

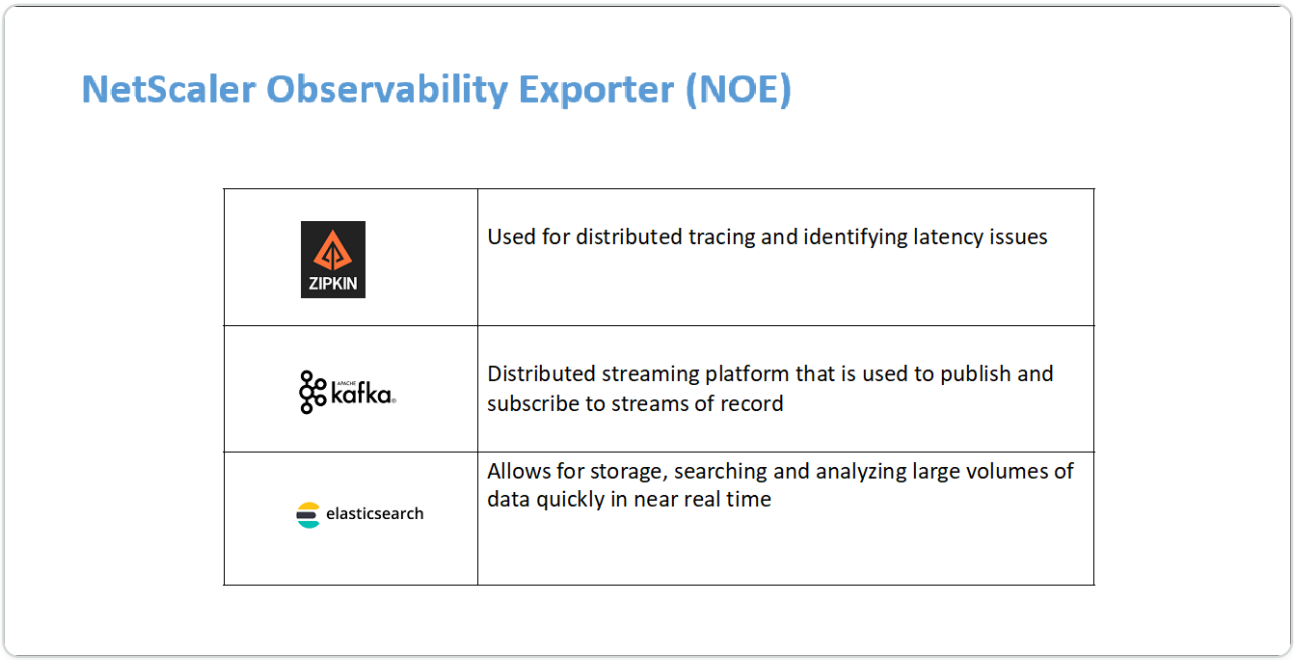
NetScaler Observability Exporter (COE) parsing

NetScaler Observability Exporter is a container which collects metrics and transactions from NetScalers and transforms them to suitable formats (such as JSON, AVRO) for supported endpoints. You can export the data collected by the NetScaler Observability Exporter to the desired endpoint. By analyzing the data exported to the endpoint, you can get valuable insights at a microservices level for applications proxied by NetScalers.

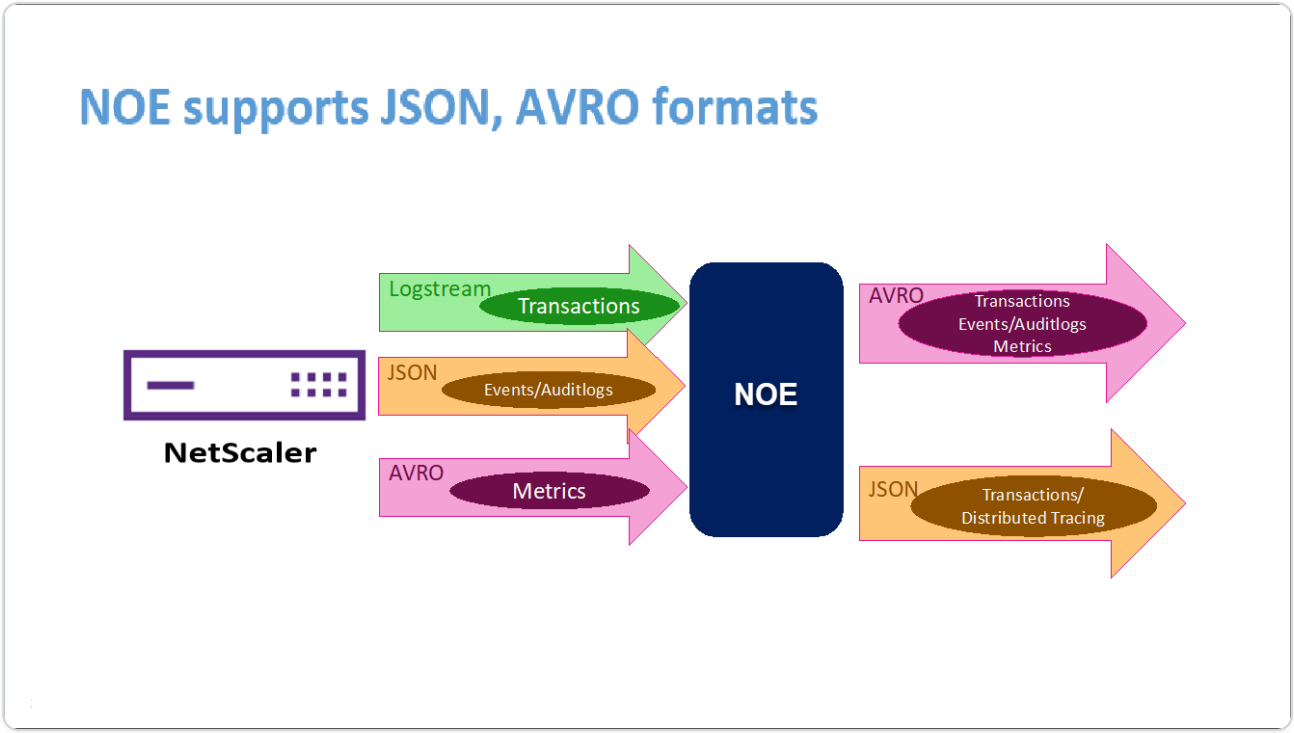
For more information on COE, see the COE GitHub.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

COE with Elasticsearch as the transaction endpoint



When Elasticsearch is specified as the transaction endpoint, NetScaler Observability Exporter converts the data to JSON format. On the Elasticsearch server, NetScaler Observability Exporter creates Elasticsearch indexes for each ADC on an hourly basis. These indexes are based on data, hour, UUID of the ADC, and the type of HTTP data (http_event or http_error). Then, the NetScaler Observability Exporter uploads the data in JSON format under Elastic search indexes for each ADC. All regular transactions are placed into the http_event index and any anomalies are placed into the http_error index.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Distributed tracing support with Zipkin

In a microservice architecture, a single end-user request may span across multiple microservices making tracking a transaction and fixing sources of errors challenging. In such cases, traditional ways for performance monitoring cannot accurately pinpoint where failures occur and what is the reason behind poor performance. You need a way to capture data points specific to each microservice handling a request and analyze them to get meaningful insights.

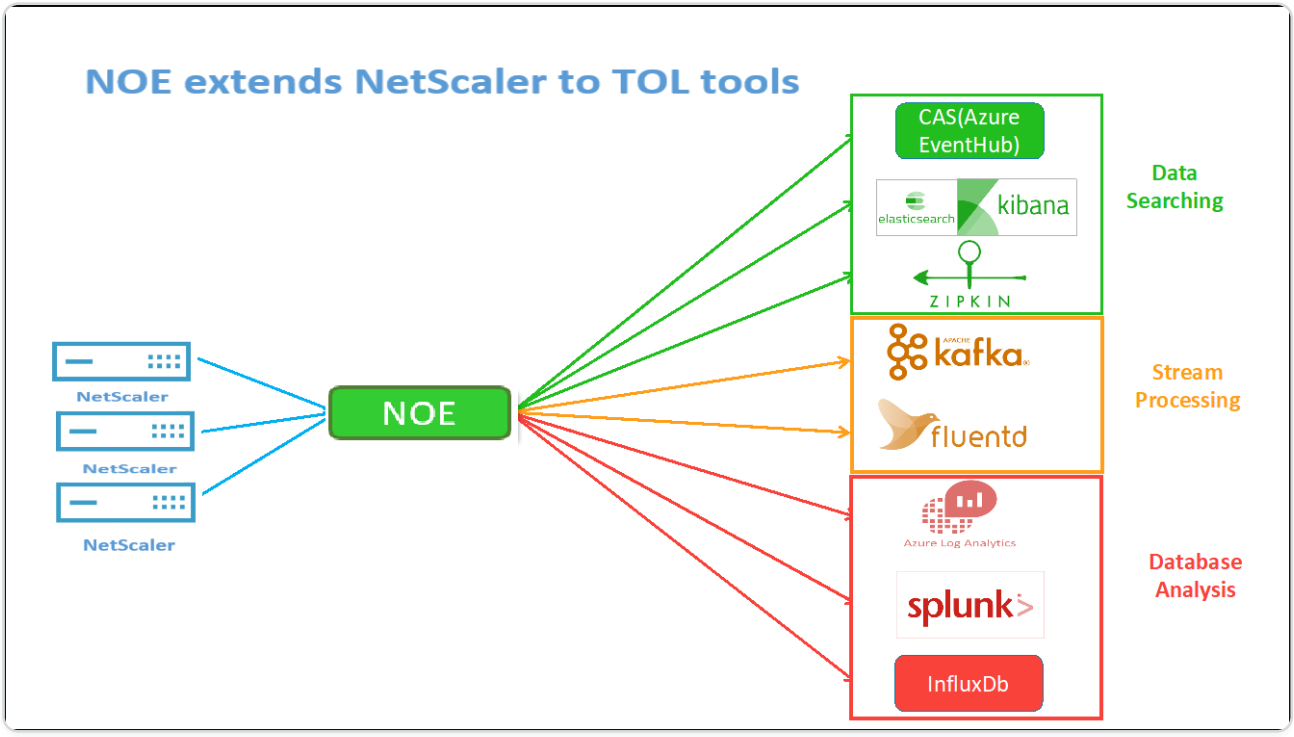
Distributed tracing addresses this challenge by providing a way to track a transaction end-to-end and understand how it is being handled across multiple microservices.

OpenTracing is a specification and standard set of APIs for designing and implementing distributed tracing. Distributed tracers allow you to visualize the data flow between your microservices and helps to identify the bottlenecks in your microservices architecture.

NetScaler Observability Exporter implements distributed tracing for NetScaler and currently supports Zipkin as the distributed tracer.

Currently, you can monitor performance at the application level using NetScaler. Using NetScaler Observability Exporter with NetScaler, you can get tracing data for microservices of each application proxied by your NetScaler CPX, MPX, or VPX.

To get started, see the GitHub Observability Exporter.



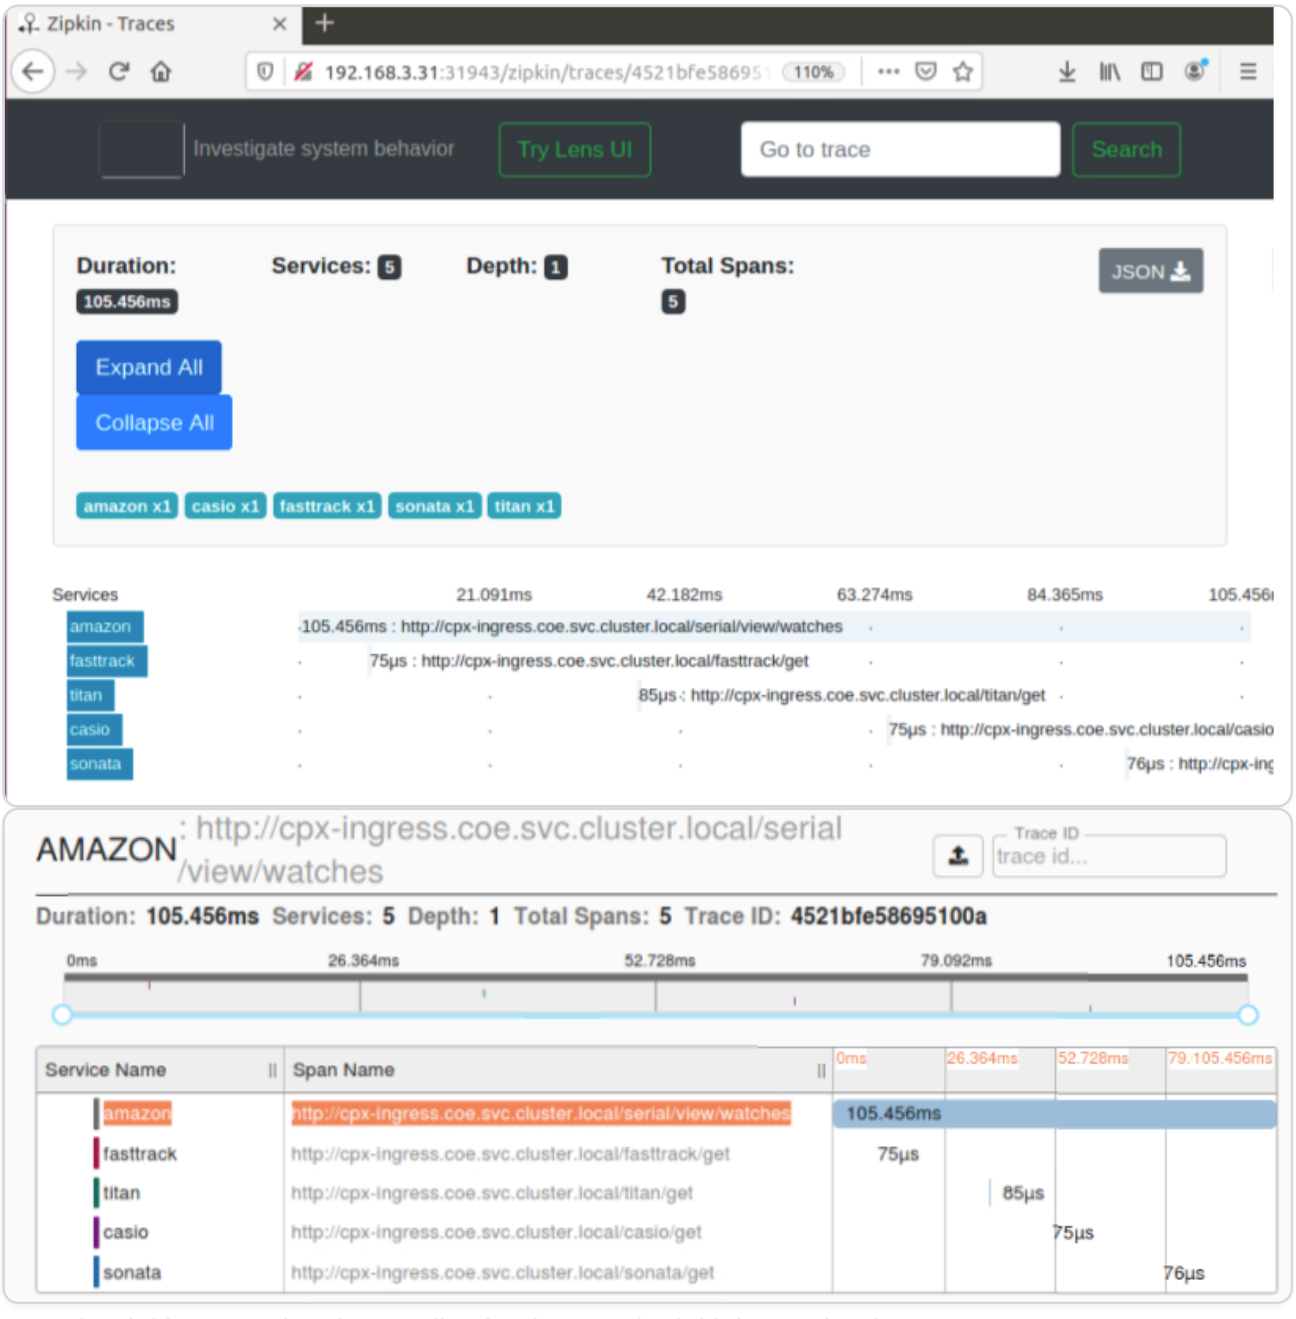
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Zipkin for application debugging

Zipkin is an open source distributed tracing system based on Dapper's paper from Google. Dapper is Google's system for its system distributed tracing in production. Google explains this in their paper - "We built Dapper to provide Google's developers with more information about the behavior of complex distributed systems". Observing the system from different angles is critical when troubleshooting, especially when a system is complex and distributed.

The following Zipkin trace data identifies a total of 5 spans and 5 services related to the Watches sample application. The trace data shows the specific span data across the 5 microservices.

To get started, see Zipkin.



Sample Zipkin span showing application latency for initial page load request:

Kibana for viewing data

Kibana is an open user interface that lets you visualize your Elasticsearch data and navigate the Elastic Stack. Do anything from tracking query load to understanding the way requests flow through your apps.

Whether you're an analyst or an admin, Kibana makes your data actionable by providing the following three key functions:

- **An open-source analytics and visualization platform.** Use Kibana to explore your Elasticsearch data, and then build beautiful visualizations and dashboards.
- **A UI for managing the Elastic Stack.** Manage your security settings, assign user roles, take snapshots, roll up your data, and more — all from the convenience of a Kibana UI.
- **A centralized hub for Elastic's solutions.** From log analytics to document discovery to SIEM, Kibana is the portal for accessing these and other capabilities.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Kibana is designed to use Elasticsearch as a data source. Think of Elasticsearch as the engine that stores and processes the data, with Kibana sitting on top.

From the home page, Kibana provides these options for adding data:

- Import data using the File Data visualizer.
- Set up a data flow to Elasticsearch using our built-in tutorials. If a tutorial doesn't exist for your data, go to the Beats Overview to learn about other data shippers in the Beats family.
- Add a sample data set and take Kibana for a test drive without loading data yourself.
- Index your data into Elasticsearch with REST APIs or Client Libraries.

Kibana uses an index pattern to tell it which Elasticsearch indices to explore. If you upload a file, run a built-in tutorial, or add sample data you get an index pattern for free and are good to start exploring. If you load your own data you can create an index pattern in Stack Management.

Step 1: Configure Index Pattern for Logstash

Step 2: Select the index and generate traffic to populate.

Step 3: generate application from the unstructured data from log feeds.

Step 4: Kibana formats the Logstash input to create reports and dashboards.

- Time Range
- Tabular View
- Hit counts based on the application.
    - Time IP, Agent, Machine.OS, Response Code (200), URL
    - Filter on values

Step 5: Visualize the data in a report of aggregations.

- Result Aggregation in a chart report (pie, graph, and so forth)

Deploy a NetScaler VPX instance

NOTE

Console Advisory Connect is enabled by default, after you install or upgrade NetScaler or NetScaler Gateway to release 13.0 build 61.xx and above. For more information see, Data governance and Console Advisory Connect.

The NetScaler VPX product is a virtual appliance that can be hosted on a wide variety of virtualization and cloud platforms:

- Citrix Hypervisor
- VMware ESX
- Microsoft Hyper-V
- Linux KVM
- Nutanix AHV
- Red Hat® OpenShift® Virtualization
- Amazon Web Services
- Microsoft Azure
- Google Cloud Platform

For more information, see the NetScaler VPX data sheet.

For more information about provisioning a NetScaler VPX instance on an SDX appliance, see Provisioning NetScaler instances.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler Application Delivery Management for NetScaler VPX

NetScaler® Application Delivery Management software is a centralized management solution that simplifies operations by providing administrators with enterprise-wide visibility and automating management jobs that need to be run across multiple instances.

You can manage and monitor NetScaler VPX instances in addition to other NetScaler products such as NetScaler Gateway, NetScaler SDX, NetScaler CPX, and Citrix SD-WAN. You can use the Application Delivery Management software to manage, monitor, and troubleshoot the entire global application delivery infrastructure from a single, unified console.

For more information, see NetScaler Application Delivery Management documentation.

Licensing overview

IMPORTANT:

File-based licensing system (also referred to as manually managed entitlements), traditionally used for activating various on-premises components, will be End of Life (EOL) on April 15, 2026. License Activation Service (LAS) is the next generation technology for product activations across the suite of Citrix products. LAS will be the only way to activate and license NetScaler instances after April 15, 2026, supporting NetScaler Flexed licenses (CPL/UHMC), legacy NetScaler Pooled licenses, and NetScaler Fixed term Bandwidth licenses. To remain supported, your NetScaler and NetScaler Console deployments must be on a LAS compatible version.

The minimum required NetScaler® versions that are LAS compatible are:

- NetScaler ADCs: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x
- NetScaler Console Service: Supported from early September 2025
- NetScaler Console on-prem: 14.1-51.x

  Note: LAS support for Console on-prem is from release 14.1-51.x onwards. However, file-based licensing is deprecated as of April 15 2026 from Console on-prem releases 14.1-51.x onwards and 13.1-60.x onwards. If you upgrade to Console on-prem release 14.1-51.x or release 13.1-60.x or later, you can continue using file-based licensing until 15th April 2026. However you must upgrade to Console on-prem release 14.1-51.x or later, and switch to LAS before 15th April 2026 because Console on-prem 13.1 does not support LAS.

All the other forms of legacy NetScaler licenses such as Pooled vCPU, CICO, perpetual will not be supported with LAS. NetScaler instances leveraging perpetual licenses without an active maintenance will become unlicensed upon upgrade to the above mentioned software versions.
LAS based licenses may not be available to customers where prohibited by law or regulations.
If you have questions or concerns, contact Customer Care. Citrix® may limit or suspend your Citrix Maintenance for non-compliance with these requirements without liability in addition to any other remedies Citrix may have at law or equity. These requirements don’t apply where prohibited by law or regulation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler offers a wide range of product editions and licensing models for MPX and VPX appliances, to meet your organization's needs.

For proper operation of a NetScaler appliance, it must have one of the NetScaler family edition licenses. The ADC product line has three family editions:

- Standard Edition

  NOTE

  The standard edition has reached End-of-Sale (EOS) and is only available for renewal.

- Advanced Edition
- Premium Edition

For more information, see the data sheet. The data sheet is available on www.netscaler.com.

Select a NetScaler edition. Then select an MPX or a VPX license offering based on the following criteria:

- Perpetual and subscription (yearly and hourly subscription)
- vCPU and bandwidth
- on-premises and cloud

IMPORTANT:

Starting from NetScaler release 14.1-51.x, there are some changes related to perpetual licensing. For details, see Changes related to perpetual licensing.

NetScaler VPX Express license

VPX Express for on-premises and cloud deployments does not require a license file, and it offers the following features:

- 20 Mbps bandwidth
- Starting with NetScaler release 14.1 build 29.65, VPX Express includes all the advanced features that are available with the Premium license.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Maximum 250 SSL sessions
- 20 Mbps SSL throughput

NetScaler fixed bandwidth (throughput) license

Fixed bandwidth perpetual licenses are EOS and you must now use fixed bandwidth subscription licenses. Fixed bandwidth subscription allows you to run a fixed throughput deployment in any form factor (MPX/SDX/VPX/BLX). After deploying your NetScaler, you must fetch your license files from the license server and download a license manually to each device (on-premises or cloud) or use LAS-based licensing. For more information on LAS, see License Activation Service.

NOTES:

- NetScaler instance stops its normal operations after the license expiry, including configuration loss and complete shutdown of traffic processing.
- Only advanced and premium editions are supported.
- Edition and bandwidth upgrades are not supported.
- Migration to pooled capacity license is not supported.

NetScaler Flexed license

NetScaler Flexed licensing is the new licensing framework aimed at simplifying the license management process. Your Flexed license includes software instance licenses (VPX/CPX/BLX, SDX, and MPX) and bandwidth capacity licenses. You must apply the Flexed licenses on the NetScaler Console service or NetScaler Console on-prem. You can then allocate them across all NetScaler form factors deployed in cloud or on-prem.

For more information about Flexed licenses on NetScaler Console, see Flexed license.

For more information about Flexed licenses on NetScaler Console service, see Flexed license.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler Pooled license

Use NetScaler Console to create a licensing framework that comprises a common bandwidth and an instance pool. For more information, see NetScaler Pooled Capacity.

NOTE:

NetScaler Console can host both Pooled and Self Managed Pool licenses. To use the required license, configure the license server on NetScaler and check out the capacity from the appropriate pool. The ADC CLI and GUI configuration steps for the Pooled and Self Managed Pool license are the same.

NetScaler Self Managed Pool license

From NetScaler release 13.1 build 30.x onwards, NetScaler instances support the Self Managed Pool license. With this license, you can simplify and automate license file uploads to a license server. Use NetScaler Console to create a licensing framework that comprises a common bandwidth or vCPU and instance pool.

To use the Self Managed Pool license, configure the license server to the `SelfManagedPool` license mode on NetScaler and check out the required capacity. Use the `show ns license` command after rebooting the NetScaler appliance to find out the license that is configured.

IMPORTANT

If your system is configured with Pooled Capacity license but want to migrate to Self Managed Pool license without impacting the traffic flow, ensure that the target server has the required Self Managed Pool license.

You can migrate only between the following compatible licenses:

- Pooled Capacity to Self Managed Pool, and conversely.
- vCPU to Self Managed vCPU, and conversely.

To migrate the license, run the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`add ns licenseserver (<licenseServerIP> | <serverName>) -forceUpdateIP -licensemode [CICO | Pooled | SelfManagedPool | VCPU | SelfManagedvCPU]`

Example:

`add licenseserver 192.0.2.246 -forceUpdateIP -licensemode selfManagedvcPU`

Configure Self Managed Pool license using the CLI

To add the license server config to the NetScaler appliance, run the following command:

```
add ns licenseserver (<licenseServerIP> | <serverName>) [-port
<positive_integer>] -licensemode [CICO | Pooled | SelfManagedPool | VCPU |
SelfManagedvCPU]
```

Example:

```
add ns licenseserver 192.0.2.246 -port 27000 -licensemode SelfManagedPool
```

NOTE:

The `show ns licenseserverpool` command displays only licenses based on the specified license mode. Hence, the licenses are fetched faster. To get an inventory of all the licenses, run the `show ns licenseserverpool -getallLicenses` command. If the license mode is not specified, the Pooled Capacity licenses are displayed by default.

To modify the system capacity, run the following command:

```
set ns capacity ((-bandwidth <positive_integer> -unit ( Gbps | Mbps )) |
-platform <platform>) [-Edition <Edition>]
```

Example:

```
set ns capacity -bandwidth 3 -unit gbps -edition enterprise
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Note:

> Capacity is checked out from the license pool of the license server.

To reboot the NetScaler appliance, run the following command:

```
reboot [-warm]
```

To display the state of all the licensed features and configured license mode, run the following command:

```
show ns license
```

Sample output of `show ns licenseserverpool` command:

```
> add licenseserver [redacted] -licensemode SelfManagedPool
 Done
> sh licenseserverpool
        Instance Total                          : 200
        Instance Available                      : 199
        Standard Bandwidth Total                : 10.00 Gbps
        Standard Bandwidth Available            : 10.00 Gbps
        Enterprise Bandwidth Total              : 10.00 Gbps
        Enterprise Bandwidth Available          : 7.00 Gbps
        Platinum Bandwidth Total                : 0 Mbps
        Platinum Bandwidth Available            : 0 Mbps
```

Sample output of `show ns licenseserverpool -getallLicenses` command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> sh licenseserverpool -getallLicenses
        Instance Total                          : 40
        Instance Available                      : 33
        Standard Bandwidth Total                : 210.00 Gbps
        Standard Bandwidth Available            : 210.00 Gbps

                         CloudBridge: NO
                       ISIS Routing: YES
                         Clustering: YES
                           CallHome: YES
                             AppQoE: YES
                   Appflow for ICA: YES
             Front End Optimization: YES
                    Large Scale NAT: YES
                          RDP Proxy: YES
                         Reputation: NO
                     URL Filtering: NO
                  Video Optimization: NO
                       Forward Proxy: NO
                    SSL Interception: NO
            Remote Content Inspection: YES
                       Adaptive TCP: NO
         Connection Quality Analytics: NO
                     Bot Management: NO
                        API Gateway: NO
                  Model Number ID: 3000
                     License Type: Enterprise License
                  Licensing mode: Self Managed Pool
Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure Self Managed Pool license using the GUI

Complete the following steps to configure the Self Managed Pool license:

1. Navigate to **System > Licenses > ADC License > Manage Licenses > Add New License**.
2. In the **Licenses** page, select the **Use remote licensing** radio button, and choose your license mode from **Remote Licensing Mode**.
3. Enter the server IP address and the license port details.
4. Provide the NetScaler Console access credentials.
5. Click **Continue**.

Changes related to perpetual licensing

Terminology description:

- **Subscription Advantage (SA) Date:** A date present in perpetual license files, introduced to limit upgrades to NetScaler versions released only up to a certain date.
- **Burn-In Date (BID):** A date associated with every NetScaler version and build.

The following changes are introduced in Perpetual licensing:

Change 1: SA Date check and enforcement:

This check and enforcement is introduced to block NetScaler customers who are running NetScaler instances on perpetual licenses with expired maintenance, resulting in unsupported deployments.

If the Burn-In Date of the NetScaler build to which you are trying to upgrade to is later than the SA date in the perpetual license file used on your NetScaler instance, your NetScaler instance becomes unlicensed after the upgrade. Some NetScaler VPX™ versions already had this check and enforcement. It is now introduced for NetScaler form-factors: VPX, MPX, and SDX starting from the following NetScaler releases:

- NetScaler ADC: 14.1 51.x, 13.1-60.x, 13.1-37.x (FIPS)
- NetScaler SVM: 14.1 51.x, 13.1-60.x

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To find the SA date of the perpetual license used on your NetScaler instance, see your perpetual license file for the SA date in `YYYY.MMDD` format as shown in the following sample image.

This check occurs during boot up after a NetScaler upgrade. To avoid your NetScaler instance becoming unlicensed, obtain a supported NetScaler license with active maintenance.

NOTE:

If you are using a perpetual license on your NetScaler instance and have active maintenance, but have not replaced the old perpetual license file with the license file provided with your latest maintenance renewal (that is, you did not use the latest license file with updated SA date and are still using the older license file with old SA date), your NetScaler becomes unlicensed if you upgrade to NetScaler builds that have the SA date check and enforcement. To avoid this impact, use the latest file that you received during your most recent maintenance renewal.

Change 2: Burn-In Date specific to each build:

Earlier, the Burn-In Date for all builds across a major NetScaler version used to be the same. For example, all builds under NetScaler version 14.1 used to have the same Burn-In Date. Now, each unique NetScaler build has its own Burn-In Date (approximately based on its release date) starting from the following NetScaler releases:

- NetScaler ADC: 14.1-51.x, 13.1 60.x, 13.1 37.x (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1 60.x

For example, from NetScaler version 14.1 build 51.x onwards, each build has a different Burn-In Date.

The following table lists the Burn-In Dates for various NetScaler releases and builds:

NETSCALER VERSION	BUILD NUMBER	BURN-IN DATE
14.1	All builds older than 51.72	Jul 12, 2023
14.1	51.72	Sep 2, 2025
14.1	56.74	Nov 9, 2025
14.1	60.52	Dec 3, 2025

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NETSCALER VERSION	BUILD NUMBER	BURN-IN DATE
13.1	All builds older than 60.32	Aug 23, 2021
13.1	60.32	Oct 31, 2025
13.1	61.25	Nov 27,2025
13.1 (FIPS)	All builds older than 37.250	Aug 23, 2021
13.1 (FIPS)	37.250	Oct 31, 2025
13.1 (FIPS)	37.255	Dec 2, 2025

The Citrix Licensing System

VPX licensing on cloud

VPX deployment is supported on public cloud providers such as Azure, AWS, and Google. For more information, see the following documents:

- VPX-Azure license
- VPX-AWS license
- VPX-GCP license

LAS for NetScaler

File-based licensing system traditionally used for activating NetScaler instances will be End of Life (EOL) on April 15, 2026. License Activation Service (LAS) is the next generation technology for product activations across the suite of Citrix products. From April 15, 2026 onwards, file-based licensing will no longer function and LAS will be the only way to activate and license NetScaler instances.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To remain supported, your NetScaler and NetScaler Console deployments must be on a LAS compatible version and must be transitioned to leverage LAS based licensing.

The minimum required NetScaler versions that are LAS compatible are:

- NetScaler ADC: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x
- NetScaler Console service: Supported from early September 2025.
- NetScaler Console on-prem: 14.1-51.x

NOTE:

LAS support for NetScaler Console on-prem is from release 14.1-51.x onwards. However, file-based licensing is deprecated as of April 15 2026 from Console on-prem releases 14.1-51.x onwards and 13.1-60.x onwards. If you upgrade to NetScaler Console on-prem release 14.1-51.x or release 13.1-60.x or later, you can continue using file-based licensing until 15th April 2026. However you must upgrade to NetScaler Console on-prem release 14.1-51.x or later, and switch to LAS before 15th April 2026 because NetScaler Console on-prem 13.1 does not support LAS.

Prerequisites

To use LAS, ensure that you have completed the following prerequisites:

- You must have a valid Citrix Cloud account. For more information about existing cloud accounts or to onboard new cloud accounts, see Account Management.
- The Organization ID (Org ID) linked to the Citrix Cloud account used for the LAS activation workflow must possess valid purchased entitlements. To view the current entitlements, see Entitlements.
- For LAS-based licensing to work on hypervised environments, ensure that the dynamic MAC settings of your hypervisor are switched off.

LAS SUPPORTED LICENSE TYPES	EXAMPLE PRODUCT NAMES AS SEEN IN MYCITRIX PORTAL	DEPLOYMENT OPTIONS (LINK TO LAS TRANSITION DOC)	
	Premium 9120Example: NetScaler SDX Fixed Term Software Premium 16030		

NOTE:

LAS does not support any license type other than the license types specified in the preceding table.

FAQ

Are there any NetScaler licenses that the LAS does not support, and what is the path forward for those licenses?

The following table describes the path forward to LAS for some of the other legacy license types not supported by LAS.

NOTE:

This list is not exhaustive.

NETSCALER LICENSE TYPES NOT SUPPORTED IN LAS	PATH FORWARD TO LAS
Any License type with expired contract end date	Expired termed licenses or perpetual licenses with expired maintenance date or expired contract expiry date are not supported in LAS. A new and supported license type needs to be purchased to transition to LAS.
Any license type running on EOL hardware	Licenses running on EOL hardware are not supported in LAS. A new active/supported hardware with its relevant supported license

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NETSCALER LICENSE TYPES NOT SUPPORTED IN LAS	PATH FORWARD TO LAS
	type needs to be purchased to transition to LAS.
NetScaler VPX/MPX/SDX perpetual license with active maintenance beyond April 15, 2026	Replacement LAS compatible license for the remainder of the contract term duration will be provided which can be used to transition to LAS. Read more.
NetScaler Gateway license type with active maintenance beyond April 15, 2026	Replacement LAS compatible license for the remainder of the contract term duration will be provided which can be used to transition to LAS.
Pooled vCPU license (also known as NetScaler virtual CPU licensing) with license contract end date beyond April 15, 2026.	Replacement LAS compatible license for the remainder of the contract term duration will be provided which can be used to transition to LAS.
NetScaler Marketplace VPX (Pay-As-You-Go VPX)	LAS works only with Citrix-provided licenses and does not support Marketplace licenses. Customers must migrate from PAYG to BYOL VPXs to avoid service impact. Read more.

NOTE:

LAS-based licenses might not be available to customers where prohibited by law or regulations.

If you have questions or concerns, contact Customer Care. Citrix may limit or suspend your Citrix Maintenance for non-compliance with these requirements without liability in addition to any other remedies Citrix may have at law or equity. These requirements don't apply where prohibited by law or regulation.

Is MPX/SDX 14000 FIPS supported in LAS?

For NetScaler MPX 14000 FIPS, LAS is supported when customers upgrade to firmware versions 14.1-66.x and 13.1-62.x. NetScaler MPX 14000 FIPS customers with perpetual licenses receive a fixed-capacity replacement license for the MPX 14080 FIPS license that supports LAS. For

© 1997–2026 Citrix Systems, Inc. All rights reserved.

customers who have deployed pooled licensing on MPX 14000 FIPS, the appliance also works when they transition to LAS.

For NetScaler SDX 14000 FIPS, LAS is supported only on SVM release 13.1 starting from build 13.1-60.x. SVM 14.1 releases are not supported.

SDX 14000 FIPS customers with perpetual licenses receive a fixed-capacity replacement license for SDX 14080 FIPS that supports LAS. For customers who have deployed pooled licensing on SDX 14000 FIPS, the appliance also works when they transition to LAS.

The following table explains the SDX 14000 FIPS LAS-supported scenarios with licensing type:

SDX 14000 FIPS LICENSING	13.1 SVM	14.1 SVM	
Perpetual	LAS is supported. Install the latest 13.1 SVM build, move to the available fixed-capacity replacement license, and follow LAS licensing steps.**Note:** If a customer has not received a fixed-capacity replacement license for a perpetual license, ask your sales contact to open a ticket with the Citrix Operations team. If the customer meets the eligibility requirements, the Operations team helps issue a replacement license, which then appears in the customer's MyCitrix portal.	Contact Citrix Support to connect with the Product Management team.	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SDX 14000 FIPS LICENSING	13.1 SVM	14.1 SVM
Pooled	LAS is supported. Install SVM build 13.1.60.x and follow the instructions to make the license available from NetScaler Console.	Contact Citrix Support to connect with the Product Management team.

Are End-of-Life (EOL) NetScaler hardware units supported by LAS?

EOL NetScaler hardware units are not supported in LAS. The following table lists the NetScaler hardware that has reached EOL in recent years.

NETSCALER EOL HARDWARE	EOL DATE	LAS SUPPORT
MPX/SDX 14000-40G (All Bandwidth and Zero-capacity)	April 1, 2025	No
MPX/SDX 14000-40S (All Bandwidth and Zero-capacity)	April 1, 2025	No
MPX/SDX 25000-40G (All Bandwidth and Zero-capacity)	April 1, 2025	No
MPX/SDX 25000A (All Bandwidth and Zero-capacity)	April 1, 2025	No
MPX 25000TA (All Bandwidth)	April 1, 2025	No
MPX 25000T (All Bandwidth)	April 1, 2025	No

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NETSCALER EOL HARDWARE	EOL DATE	LAS SUPPORT
MPX/SDX 14000 (All Bandwidth and Zero-capacity)	October 1, 2024	No
MPX/SDX 22000 (All Bandwidth and Zero-capacity)	July 1, 2024	No
MPX 5550, MPX 5650, MPX 8005, MPX 8010, MPX/SDX 8015, MPX 8200, MPX/SDX 8400, MPX/SDX 8600, MPX/SDX 8800	January 1, 2024	No

I am using Admin Partitions on NetScaler. Will the transition to LAS impact my deployment?

If you are using VPX or SDX instances, there should be no impact. However, for MPX deployments transitioning from Fixed or Perpetual license types to Pooled or Flexed licensing, certain modifications might be required. For detailed instructions, see Admin Partition missing/fail to load after migrating from NetScaler local license to Pooled/Flexed license.

If I have transitioned from legacy file-based licensing to LAS-based licensing but still have legacy file-based licenses on my NetScaler or NetScaler Console, will this configuration cause a conflict?

There is a known issue affecting NetScaler SDX that has migrated from file-based licensing to LAS when specific criteria are met. To understand the scope, impact, and required resolution for this issue, see Important LAS Advisory: Action required for SDX customers migrating to LAS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

I am using LAS with NetScaler Console on-prem Cloud Connect. What notification support is available for this deployment?

For information related to Notifications for LAS with Console on-prem Cloud Connect, see Notification behavior for LAS with NetScaler Console on-prem Cloud Connected.

Are there any known issues with LAS exception of type license file extension?

There is a critical issue related to the use of LAS exception license file extension blobs across NetScaler components. Review the following details carefully to take the recommended actions as applicable.

1. **If you are using or planning to use LAS exception (license file extension type) with NetScaler SDX 13.1-60.x or later, or Console on-prem 13.1-60.x or later, this section applies to you.** This does not apply to NetScaler SDX 14.1 or Console on-prem 14.1.

   NetScaler Console on-prem:

   If you are using or planning to use LAS exception blobs of type license file extension on Console on-prem version 13.1-60.x or later, with Console-based license types (for example, CPL, UHMC, Pooled Bandwidth), note the following:

   A critical issue (JIRA ID: NSADM-127861) will cause the Console on-prem to become non-functional, and the LAS exception license file extension will not be honored.

   To resolve this:

   - Upgrade to Console on-prem releases with the fix: 13.1-62.27 or 13.1-61.28 or 13.1-60.33.
   - Refer to the *LAS Exception License File Extension* documentation for steps and follow all the steps in the documentation if you have not already completed the steps on an earlier version.

   NetScaler SDX (SVM):

   If you are using or planning to use LAS exception blobs of type license file extension on SVM 13.1-60.x or later, with NetScaler local license types (for example, Fixed Capacity Subscription or Perpetual licenses), note the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

A critical issue (JIRA ID: NSSVM-7346) will cause SDX to become non-functional, and the LAS exception license file extension will not be honored.

To resolve this:

- Upgrade to SVM releases with the fix: 13.1-62.27 or 13.1-61.28 or 13.1-60.33.
- Refer to the *LAS Exception License File Extension* documentation for steps and follow all the steps in the documentation if you have not already completed the steps on an earlier version.

2. **If you are using or planning to use LAS exception (license file extension type) with NetScaler ADC, this message applies to you.**

   NOTE:

   The following details have been updated in the *LAS Exception License File Extension* documentation as well.

   NetScaler ADC:

   - When generating the LAS exception license file extension blob, do not use the Host ID shown in the NetScaler GUI.
   - Always use the Host ID obtained from the NetScaler CLI.

   If you have already used the NetScaler GUI-based Host ID, regenerate the LAS exception license file extension blob using the Host ID from the NetScaler CLI command output and re-perform all the steps. Refer to the *LAS Exception License File Extension* documentation for detailed steps.

In case of LAS with Pooled or Flexed license type, what is a valid bandwidth to checkout/allocate to a NetScaler instance? Is there any known issue that I must be aware of?

For VPX, CPX, BLX: The starting minimum bandwidth is 20 Mbps. In all cases, the value must always be in multiples of 10 Mbps.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT NOTE DETAILING A KNOWN ISSUE:

Bandwidth allocation in non-multiples of 10 Mbps is considered invalid.

While Console service now auto-heals this situation (by rounding off the bandwidth to the nearest higher multiple of 10 Mbps), it is a known issue with NetScaler licensed using Console on-premises release 14.1-73.x or earlier that can cause your NetScaler instances to become unlicensed. This known issue, depending on your NetScaler version and build, could either hide silently and cause NetScaler to go unlicensed on the next reboot or it could put your NetScaler in grace and eventually cause it to become unlicensed. The issues have been release noted with NSCONFIG-14995 and NSHELP-44344 in the following release notes:

- 14.1-73.33: Product Documentation
- 13.1-64.22: Product Documentation

Given this issue, it is important that you review the bandwidth checked out by all your NetScaler VPX/BLX/CPX instances and take action as soon as possible to correct or update the bandwidth value to a multiple of 10 Mbps.
For MPX, SDX: Depending on the MPX or SDX model/platform, the minimum and maximum allowed bandwidth checkout varies. In all cases, it must be in multiples of 1 Gbps. Refer to the following documentation for more details.

- Console service documentation - Minimum and maximum capacity for checkout
- Console on-premises documentation - Minimum and maximum capacity for Flexed and Pooled licensing

If my NetScaler is LAS licensed using Pooled/Flexed license type with Console on-premises and I want to change the license server from one Console on-premises to another (or from Console on-premises to Console service), how can I do it?

To move NetScaler instances licensed using Console on-premises 1 to Console on-premises 2 as the licensing server, follow these steps:

- **Step 1:** Deploy and ready the Console on-premises 2 with all the license entitlements reflecting in Console on-premises 2.
- **Step 2:** Add or manage the NetScaler instances on Console on-premises 2.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Step 3:** You will see the NetScaler instances under the **Migrate** or **License with LAS** option in Console on-premises 2. Use these workflows to re-license the NetScaler instance from Console on-premises 2.
- **Step 4:** Remove NetScaler from Console on-premises 1, only after Console on-premises 2 starts to act as the license server. Otherwise, Console on-premises 1 will continue to show the devices in the **Migrate** option and an alarm would appear on Console on-premises 1 that there are devices in grace, which is incorrect.

License Activation Service

IMPORTANT:

File-based licensing system (also referred to as manually managed entitlements), traditionally used for activating various on-premises components, will be End of Life (EOL) on April 15, 2026. License Activation Service (LAS) is the next generation technology for product activations across the suite of Citrix products. LAS will be the only way to activate and license NetScaler instances after April 15, 2026, supporting NetScaler Flexed licenses (CPL/UHMC), legacy NetScaler Pooled licenses, and NetScaler Fixed term Bandwidth licenses. To remain supported, your NetScaler and NetScaler Console deployments must be on a LAS compatible version.

The minimum required NetScaler® versions that are LAS compatible are:

- NetScaler ADCs: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS), 14.1-66.68 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x
- NetScaler Console Service: Supported from early September 2025
- NetScaler Console on-prem: 14.1-51.x

  Note: LAS support for Console on-prem is from release 14.1-51.x onwards. However, file-based licensing is deprecated as of April 15 2026 from Console on-prem releases 14.1-51.x onwards and 13.1-60.x onwards. If you upgrade to Console on-prem release 14.1-51.x or release 13.1-60.x or later, you can continue using file-based licensing until 15th April 2026. However you must upgrade to Console on-prem release 14.1-51.x or later, and switch to LAS before 15th April 2026 because Console on-prem 13.1 does not support LAS.

All the other forms of legacy NetScaler licenses such as Pooled vCPU, CICO, perpetual will not be supported with LAS. NetScaler instances leveraging perpetual licenses without an active maintenance will become unlicensed upon upgrade to the above mentioned software versions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LAS-based licenses may not be available to customers where prohibited by law or regulations. If you have questions or concerns, contact Customer Care. Citrix® may limit or suspend your Citrix Maintenance for non-compliance with these requirements without liability in addition to any other remedies Citrix may have at law or equity. These requirements don't apply where prohibited by law or regulation.
Before starting your transition to LAS, we recommend reading LAS for NetScaler. This ensures you understand the general prerequisites, the supported or unsupported license types, the accurate workflow for your specific license and deployment types along with other important information.

License Activation Service (LAS) is a new cloud-based licensing solution that provides an alternative to traditional file-based licensing. LAS introduces new modules for activation of Citrix and NetScaler products, ensuring a seamless and modern approach to license management.

NOTE:

LAS is a licensing mechanism, not a license type. LAS supports Fixed-term Bandwidth licensing for NetScaler deployments. All other forms of legacy NetScaler licenses, such as perpetual licenses, are not supported with LAS.

NetScaler version compatibility for LAS

To use LAS, your NetScaler must be running one of the following minimum versions or later:

- **NetScaler ADC:** 14.1 build 51.x, 13.1 build 60.x, 13.1 build 37.246 (FIPS)
- **NetScaler SVM:** 14.1 build 51.x, 13.1 build 60.x

NOTE:

For SDX appliances, upgrade the Management Service (SVM) to a LAS-supported build and transition to LAS-based licensing. The VPX build version does not impact LAS compatibility.

Prerequisites

To use LAS, ensure that you have completed the following prerequisites:

- You must have a valid Citrix Cloud account. For more information about existing cloud accounts or to onboard new cloud accounts, see Account Management.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The Organization ID (Org ID) linked to the Citrix Cloud account used for the LAS activation workflow must possess valid purchased entitlements. To view the current entitlements, see Entitlements.
- Ensure your NetScaler is running on a LAS-compatible version.

Transition to LAS by using the NetScaler GUI

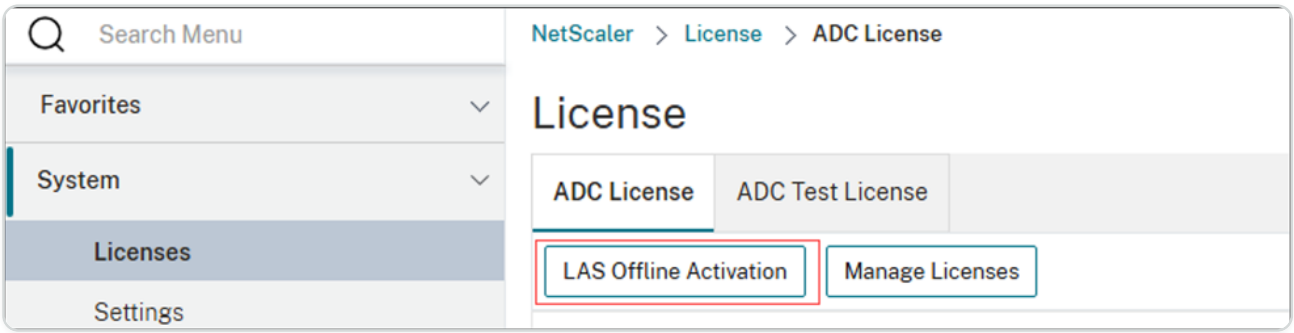
Follow the steps described in this section, if you are:

- A Fixed-term Bandwidth customer using file-based licensing and moving to Fixed-term Bandwidth LAS-based licensing.
- Have an unlicensed NetScaler and want to use Fixed-term Bandwidth LAS-based licensing.
- A perpetual license customer using file-based licensing and moving to Fixed-term Bandwidth LAS-based licensing.

NOTE:

If the license type is NetScaler Flexed license (CPL/UHMC) or Pooled Bandwidth license, see NetScaler Console documentation instead of this documentation.

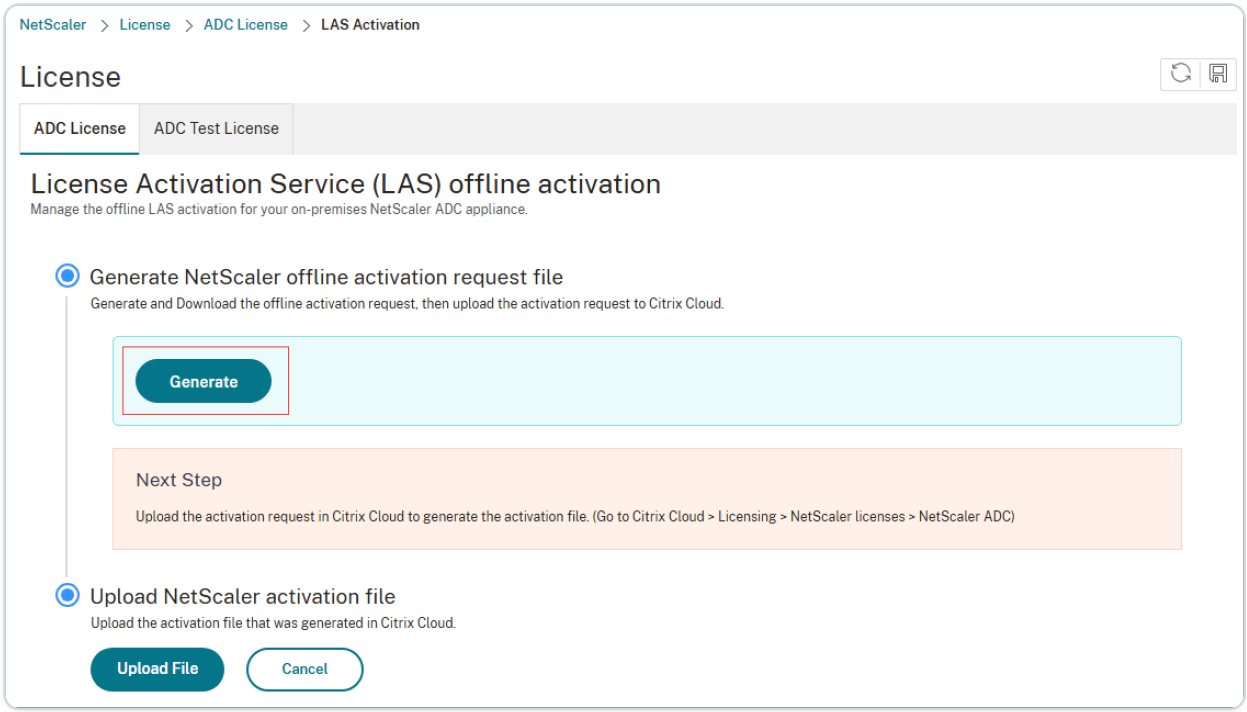
Step 1: In the NetScaler GUI, navigate to **System > Licenses > ADC License** and select the LAS Activation option.



Step 2: LAS activation begins by generating an activation request file that contains the unique identity information for a specific NetScaler instance.

1. To generate the LAS activation request file, under the **Generate NetScaler offline activation request file** section, click **Generate**.

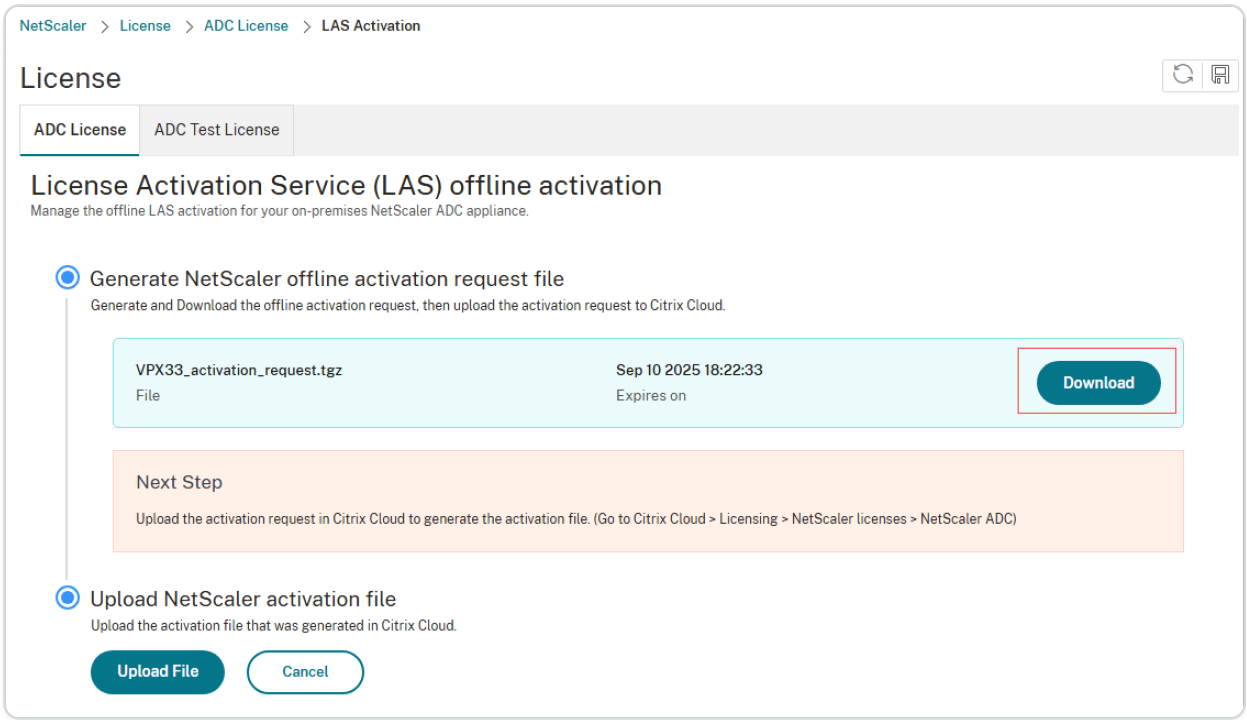
© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. After the activation request file is generated, click **Download** to save it to your local system.

NOTE:

The activation request file expires after 7 days. Complete the activation process described in **Step 3** within this timeframe to ensure that the file remains valid.



Step 3: Upload the activation request file generated from **Step 2** to Citrix Cloud™ (LAS UI) to generate the license activation file or blob for your NetScaler.

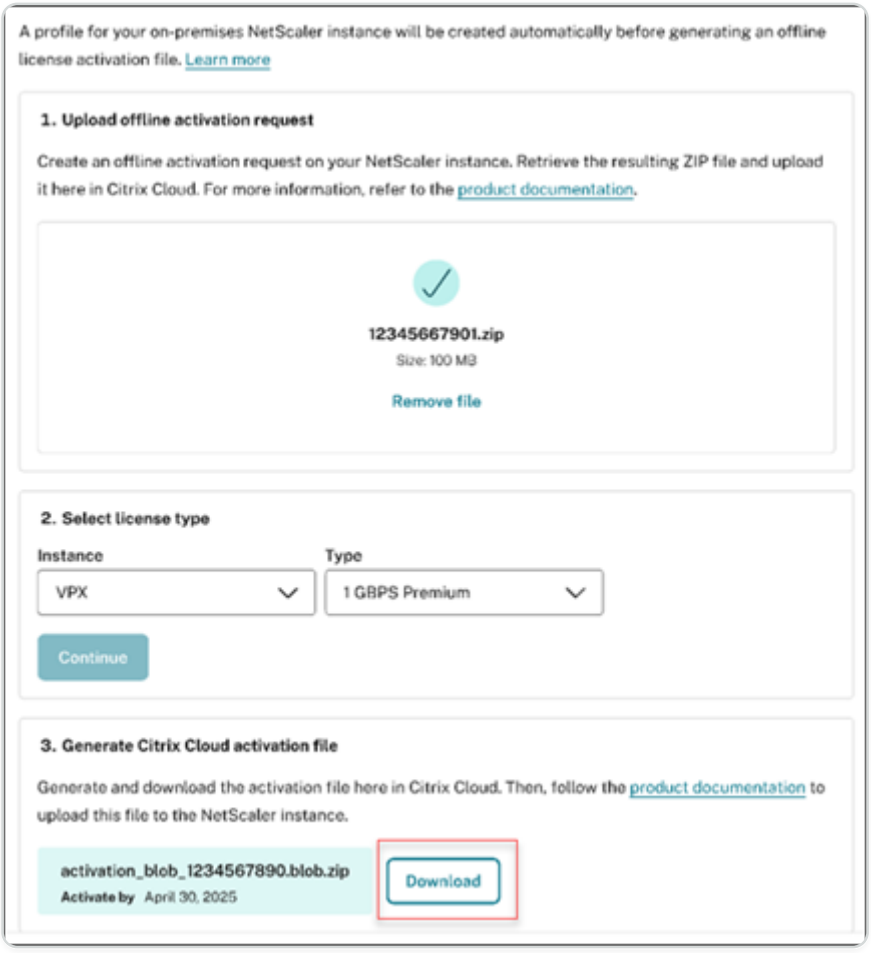
© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Log in to Citrix Cloud and navigate to **Citrix Cloud > Licensing > NetScaler licenses > NetScaler ADC**.
2. Upload the activation request file generated in **Step 2**.
3. After the file uploads successfully, select the required license type for your NetScaler.

> **NOTE:**
>
> If you have multiple Fixed-term Bandwidth entitlements, a drop-down menu displays all available entitlements. Choose the appropriate one for this NetScaler instance.

4. After selecting the license type, generate and download the license activation file or blob.

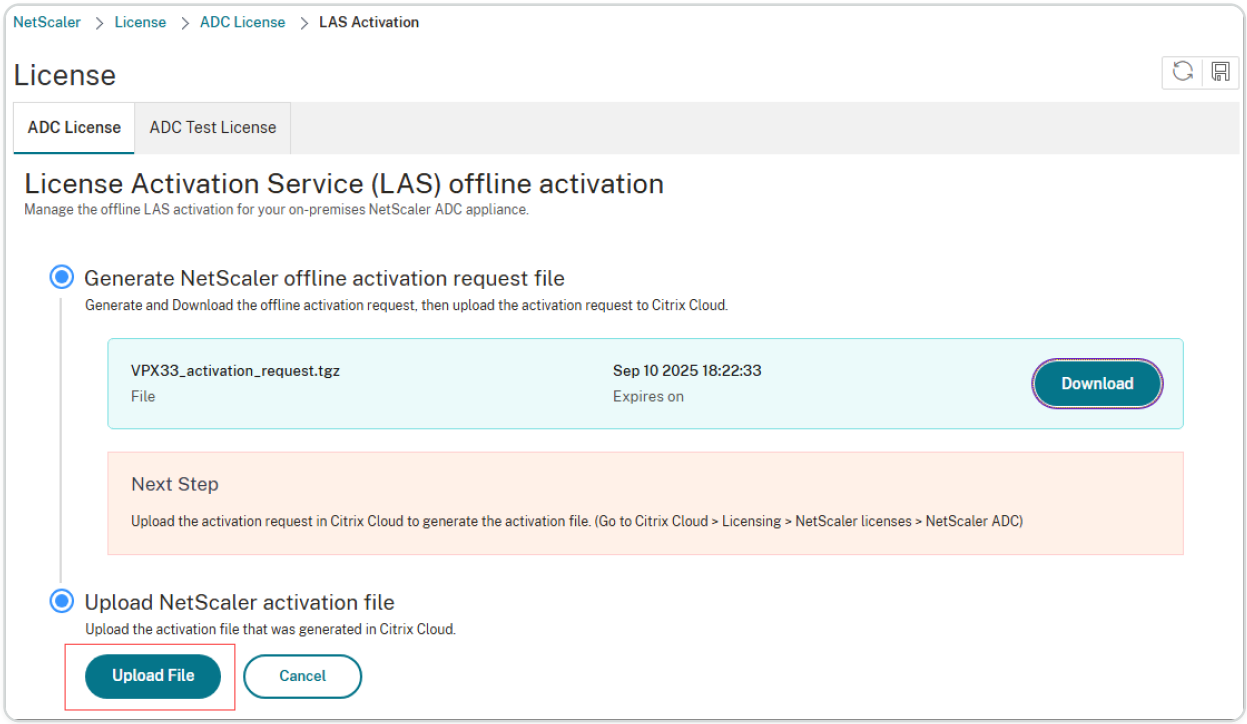
> **NOTE:**
>
> The license activation file or blob remains valid for one year from generation.



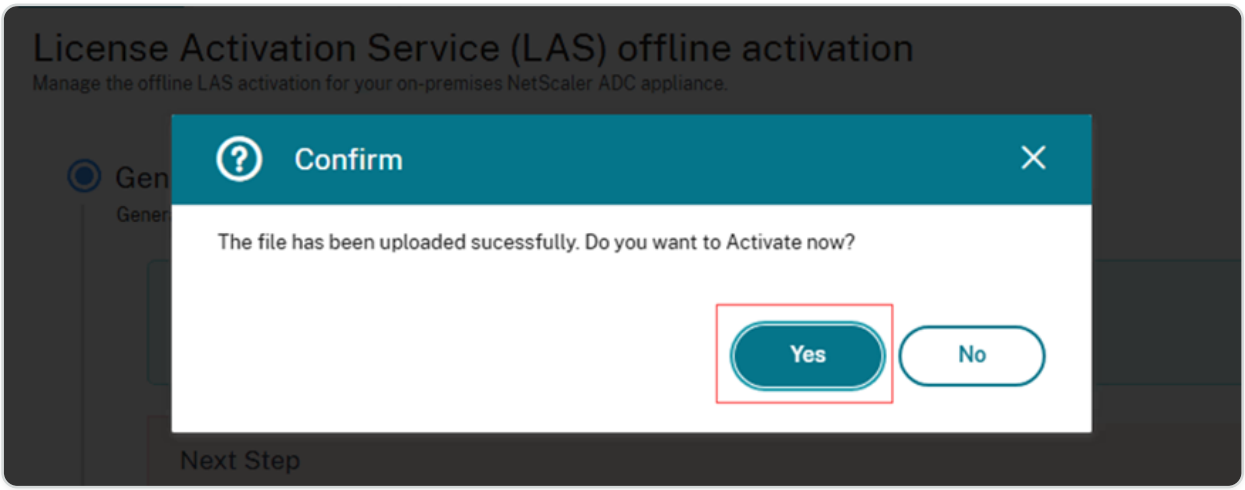
Step 4: Return to the NetScaler GUI, navigate to **System > Licenses > ADC License** and select the LAS Activation option.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. In the **Upload NetScaler activation file** section, click **Upload File** to upload the license activation file or blob generated in **Step 3**.



2. After you upload the activation file, confirm the activation by clicking **Yes**.



3. Click **Reboot** to reboot NetScaler for the license to take effect.

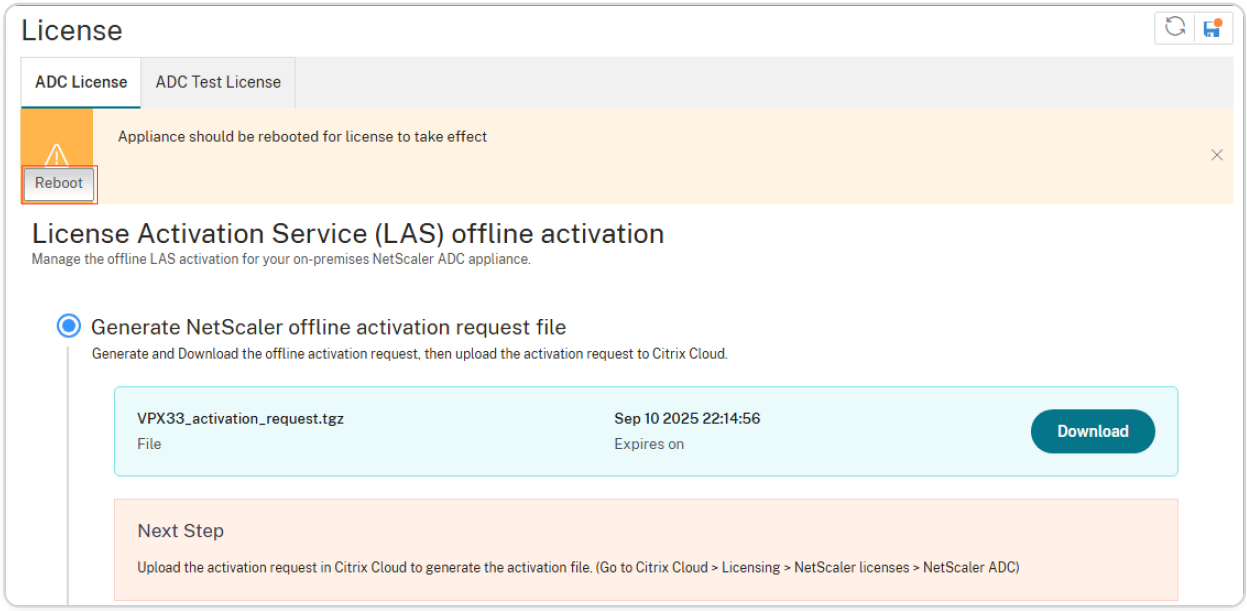
NOTE:

A reboot is not required in the following scenarios:

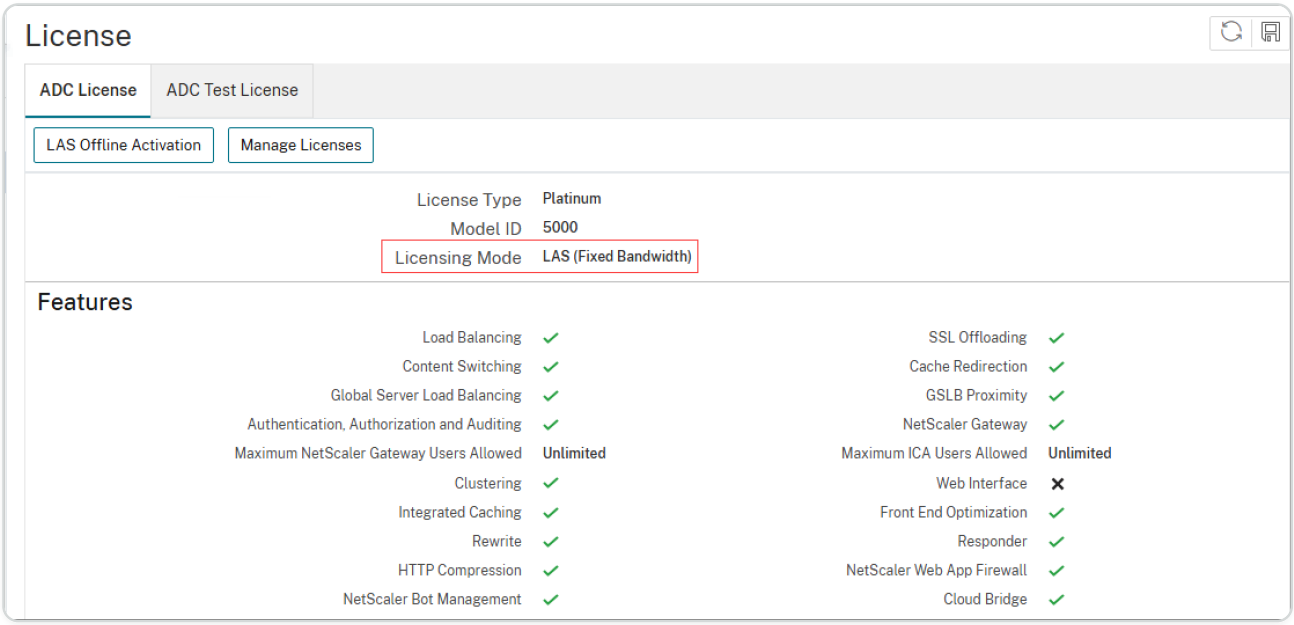
- You have the same Perpetual license file (file-based licensing) or Fixed-term Bandwidth license file (file-based licensing) switching to the same Fixed-term Bandwidth license entitlement using LAS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- You are an existing LAS user, and are performing these steps after renewing your license contract.



Step 5: Your NetScaler instance is now licensed through LAS.

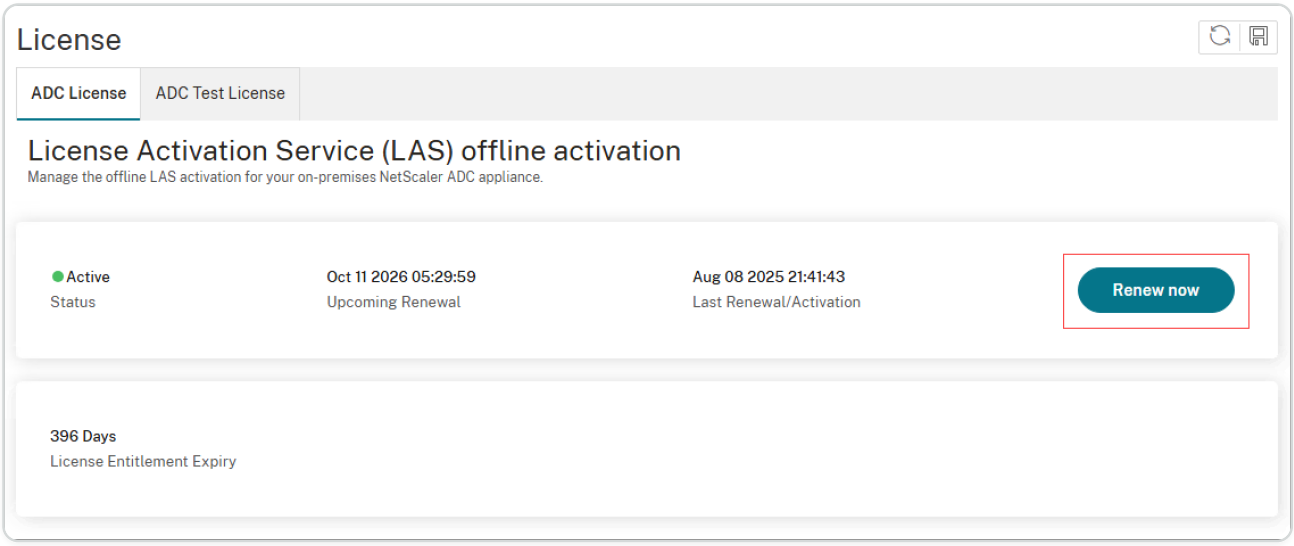


Step 6: Monitor and manage license activation file or blob to ensure continuous operation.

The license activation file or blob remains valid for one year. You can view both the last renewal or activation date and the upcoming renewal or activation date in the interface.

To maintain continuous NetScaler functionality, click **Renew Now** and repeat **Step 2** through **Step 5** before the upcoming renewal date expires.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



IMPORTANT:

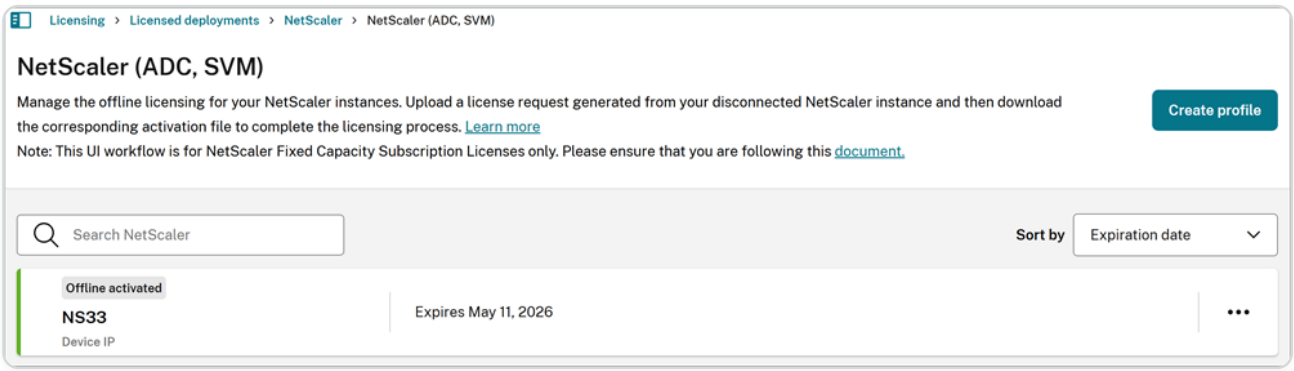
If you do not renew and apply the license activation file or blob in time, NetScaler becomes unlicensed.

Step 7: View LAS activation blobs by logging into **Citrix Cloud** and navigating to **Licensing > NetScaler licenses > NetScaler ADC**.

NOTE:

By default, LAS uses a system identifier (`lsguid`) to identify the NetScaler deployment for the activation blob listing.

If the host name is selected instead of the system identifier (`lsguid`), the host name appears in the **NetScaler GUI** field.



For NetScaler ADC HA deployments:

Ensure that both nodes are running LAS-compatible versions/builds. Follow these steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Complete the licensing process (step 1 through step 7) for the secondary node. This may require a reboot for the node as mentioned in step 4.
2. Perform a force failover. The old primary node becomes the new secondary node.
3. Complete the licensing process (step 1 through step 7) on the new secondary node (formerly the primary node). This may require a reboot as mentioned in step 4.

NOTE:

This applies only to VPX, MPX, and BLX form factors. It does not apply to VPX instances on SDX.

For NetScaler ADC Cluster deployments:

Complete the licensing process (step 1 through step 7) individually on each node, one at a time. The order in which you process the nodes does not matter.

NOTE:

This applies only to VPX, MPX, and BLX form factors. It does not apply to VPX instances on SDX.

Transition to LAS by using the NetScaler CLI

Follow the steps described in this section, if you are:

- A Fixed-term Bandwidth customer using file-based licensing and moving to Fixed-term Bandwidth LAS-based licensing.
- Have an unlicensed NetScaler and want to use Fixed-term Bandwidth LAS-based licensing.
- A perpetual license customer using file-based licensing and moving to Fixed-term Bandwidth LAS-based licensing.

Step 1: Generate an activation request file that contains the unique identity information for your NetScaler instance.

1. Generate the LAS activation request file by running the following command in NetScaler CLI:

```
show ns licenseactivationdata
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. After the activation request file is generated, you can see it at the following path:

   `"/nsconfig/license/<FileName>"`

3. Use SCP to transfer the file from the NetScaler to your local computer.

NOTE:

The activation request file expires after 7 days. Complete the next steps within this timeframe to ensure that the file remains valid.

Step 2: Upload the activation request file generated from **Step 1** to Citrix Cloud (LAS UI) to generate the license activation file for your NetScaler.

NOTE:

Step 2 cannot be performed using CLI.

1. Log in to Citrix Cloud and navigate to **Citrix Cloud > Licensing > NetScaler licenses > NetScaler ADC**.
2. Upload the activation request file generated from **Step 1**.
3. After the file uploads successfully, select the required license type for your NetScaler.

   NOTE:

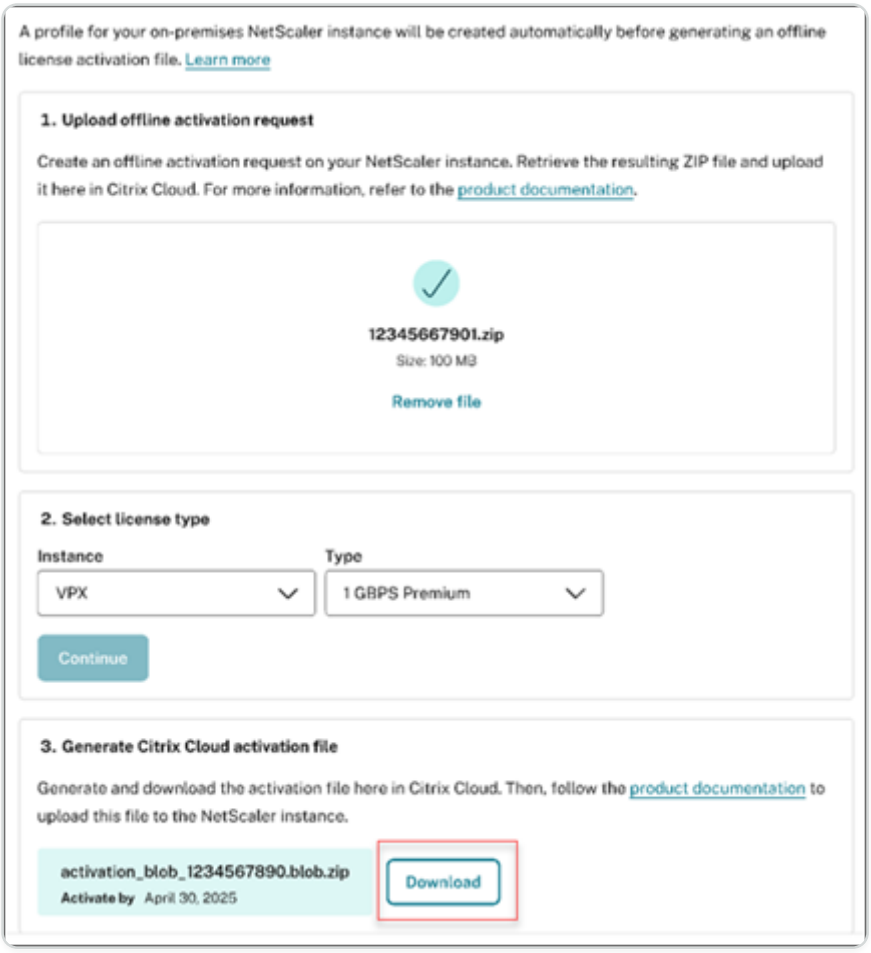
   If you have multiple Fixed-term Bandwidth entitlements, a drop-down menu displays all available entitlements. Choose the appropriate one for this NetScaler instance.

4. After selecting the license type, generate and download the license activation file.

   NOTE:

   The license activation file or blob remains valid for one year from generation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Step 3: Transfer the license activation file generated from **Step 2** to your NetScaler and activate it.

1. Use SCP to copy the license activation file generated in **Step 2** from your local system to the following NetScaler directory:

   `/nsconfig/license`

2. After transferring the file to this location, run the following command to activate the license on your NetScaler:

   ```
   apply ns laslicense -filename <activation_blob_file> -filelocation
   <path_to_license_directory> -fixedBandwidth
   ```

   Example:

   ```
   apply ns laslicense -filename NS_activation_blob.tgz -filelocation /
   nsconfig/license -fixedBandwidth
   ```

```
> apply ns laslicense -filename NS_activation_blob.tgz -filelocation /nsconfig/license -fixedBandwidth
Warning: The configuration changes will not take effect until the system is rebooted
 Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. If you get a Warning to reboot, reboot NetScaler for the license to take effect.

   NOTE:

   A reboot is not required in the following scenarios:

   - You have the same Perpetual license file (file-based licensing) or Fixed-term Bandwidth license file (file-based licensing) switching to the same Fixed-term Bandwidth license entitlement using LAS.
   - You are an existing LAS user, and are performing these steps after renewing your license contract.

Step 4: Your NetScaler instance is now licensed through LAS. Verify the applied license using the following command:

```
show ns license
```

The command output displays the current license status and details:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> show ns license
       License status:
                        Web Logging: YES
                  Surge Protection: YES
                    Load Balancing: YES
                 Content Switching: YES
                 Cache Redirection: YES
               Compression Control: YES
                 Delta Compression: NO
                    SSL Offloading: YES
       Global Server Load Balancing: YES
                   GSLB Proximity: YES
                  Dynamic Routing: YES
                Content Filtering: YES
              Content Accelerator: YES
               Integrated Caching: YES
                          SSL VPN: YES  (Maximum users = Unlimited)  (Maximum ICA users = Unlimited)
                              AAA: YES
                   OSPF Routing: YES
                    RIP Routing: YES
                    BGP Routing: YES
                        Rewrite: YES
          IPv6 protocol translation: YES
               Application Firewall: YES
                        Responder: YES
                  NetScaler Push: YES
                         AppFlow: YES
                     CloudBridge: YES
                   ISIS Routing: YES
                     Clustering: YES
                       CallHome: YES
                         AppQoE: YES
                  Appflow for ICA: YES
           Front End Optimization: YES
                  Large Scale NAT: YES
                       RDP Proxy: YES
                      Reputation: YES
                   URL Filtering: NO
                Video Optimization: YES
                     Forward Proxy: YES
                  SSL Interception: YES
          Remote Content Inspection: YES
                    Adaptive TCP: YES
       Connection Quality Analytics: YES
                  Bot Management: YES
                     API Gateway: YES
                Model Number ID: 5000
                   License Type: Platinum License
                Licensing mode: LAS (Fixed Bandwidth)
              Days to expiration: 405
Done
```

Step 5: Monitor and manage license activation file or blob renewal to ensure continuous operation.

NOTE:

The license activation file or blob remains valid for one year. To view the last activation date and upcoming renewal date, use the following command:

```
show ns laslicense
```

The command output displays the LAS license details including activation and renewal dates:

```
> show ns laslicense
       Status:  ACTIVE          DaysToExpiration:  401   Renewalprev:  1754669503 Renewalnext:  1791676799
       Renewalprevdate:  Fri Aug  8 21:41:43 2025 Renewalnextdate:  Sun Oct 11 05:29:59 2026
Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To maintain continuous NetScaler functionality, repeat **Step 1** through **Step 4** before the upcoming renewal date expires.

IMPORTANT:

If you do not renew and apply the license activation file or blob in time, your NetScaler becomes unlicensed.

For NetScaler ADC HA deployments:

Ensure that both nodes are running LAS-compatible versions/builds. Follow these steps:

1. Complete the licensing process (step 1 through step 5) for the secondary node. This may require a reboot for the node as mentioned in step 3.
2. Perform a force failover. The old primary node becomes the new secondary node.
3. Complete the licensing process (step 1 through step 5) on the new secondary node (formerly the primary node). This may require a reboot as mentioned in step 3.

NOTE:

This applies only to VPX, MPX, and BLX form factors. It does not apply to VPX instances on SDX.

For NetScaler ADC Cluster deployments:

Complete the licensing process (step 1 through step 5) individually on each node, one at a time. The order in which you process the nodes does not matter.

NOTE:

This applies only to VPX, MPX, and BLX form factors. It does not apply to VPX instances on SDX.

License activation file behavior and expiry

The license activation file or blob remains valid for one year from the date of generation. Customers are responsible for tracking the upcoming renewal date and renewing the file before it expires.

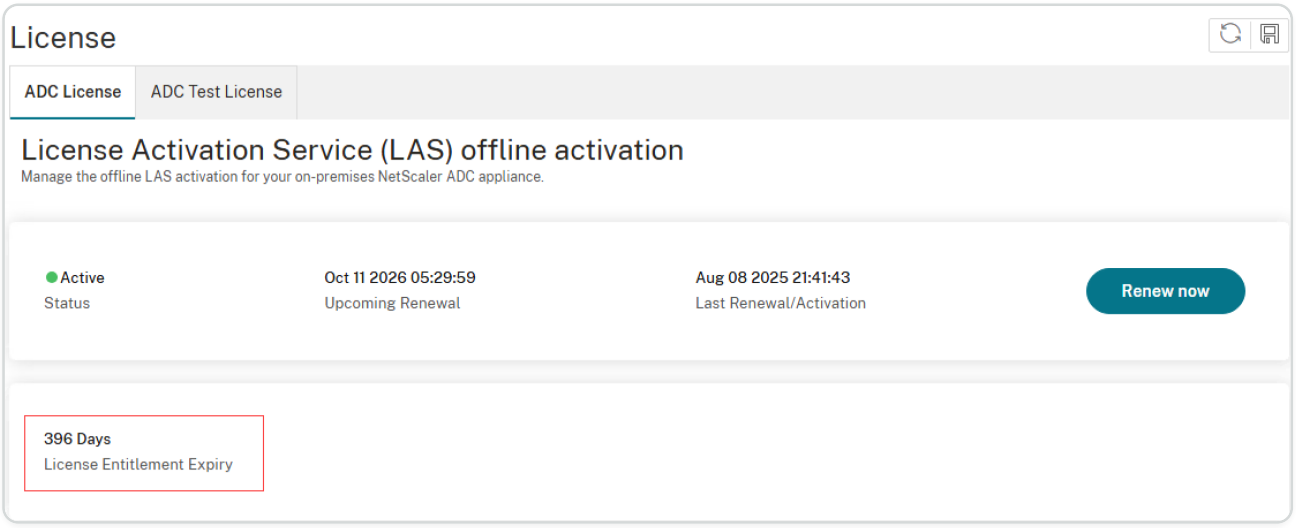
© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT:

Failure to renew the license activation file before its expiration date results in the NetScaler becoming unlicensed.

License contract expiry

The number of days remaining until your license contract expires, is shown under **License Entitlement Expiry** by navigating to **System > Licenses > ADC License**.



To ensure smooth functioning of your NetScaler, you must renew your license contract and complete the steps outlined in the following sections before your license contract expires:

- For GUI instructions, see Transition to LAS by using the NetScaler GUI.
- For CLI instructions, see Transition to LAS by using the NetScaler CLI.

IMPORTANT

- If the license contract is not renewed in time, your NetScaler becomes unlicensed.
- NetScaler instance stops its normal operations after the license expiry, including configuration loss and complete shutdown of traffic processing.

Information sent to LAS during LAS licensing workflow

This section details all information sent as part of the request for an activation blob to LAS during every initial request and each LAS activation blob refresh request.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following table summarizes the parameters sent to LAS during the licensing workflow.

PARAMETER	DESCRIPTION	NEED FOR IT IN LAS WORKFLOW
type	Hardcoded to identify the LAS deployment type for offline NetScaler	For LAS-side tracking
lsguid/lsid	Unique ID for NetScaler	LAS binding parameter
NSIP and hostname	Current hostname of NetScaler in the IP_hostname format	For LAS-side tracking
lsbuild	NetScaler version and build	For LAS-side tracking
requesttime	Timestamp when the request package (tgz) was created	LAS binding parameter
orgid	Organization ID of customer	LAS binding parameter
ccid	CC ID of customer	LAS binding parameter
platform	NetScaler form factor and model	LAS binding parameter
burnindate	Software release date for the NetScaler version and build	For LAS-side tracking
lastactivationid	Previous LAS activation ID sent during renewal	LAS binding parameter
uiver	Ensures file integrity verification	File integrity verification

Configure LAS activation identifier

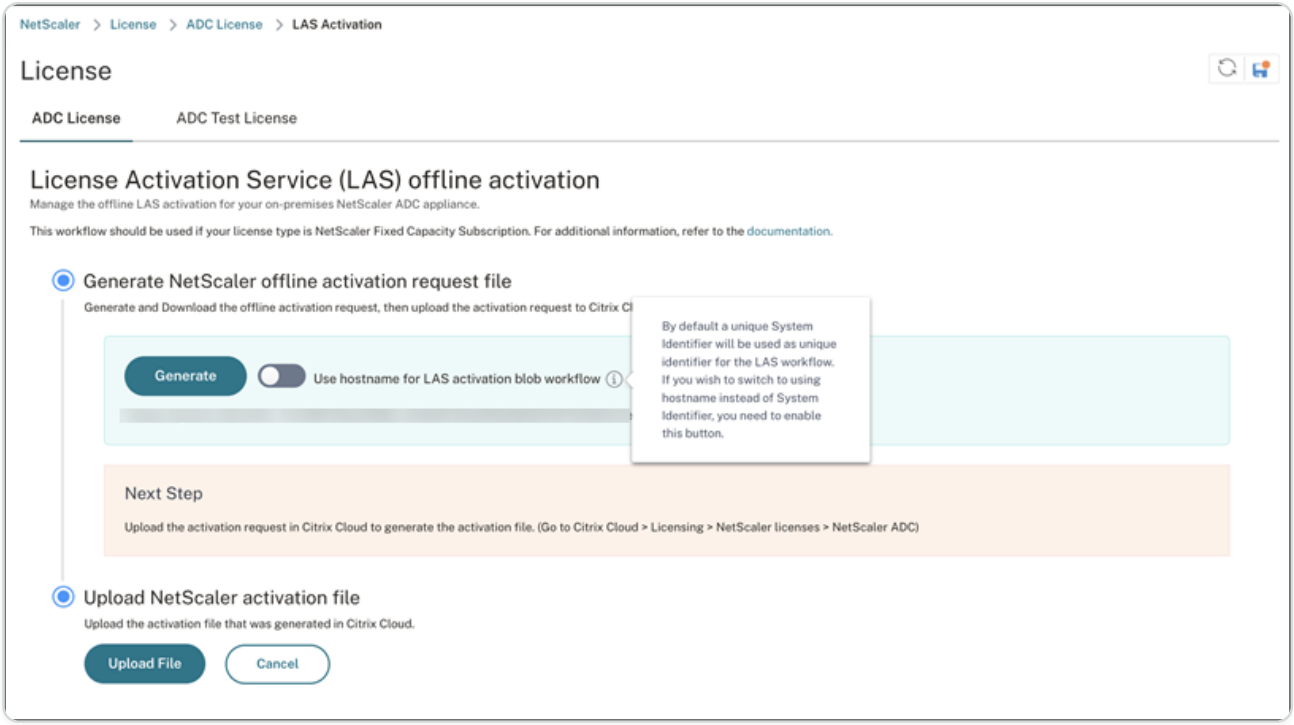
Starting from NetScaler ADC/SVM 14.1-60.57, NetScaler ADC/SVM 13.1-61.26, and NetScaler FIPS 13.1-37.259, the LAS-based licensing workflow for NetScaler (ADC/SVM) deployments no longer uses the IP address and host name. Instead, a system identifier (`lsguid`) is used by LAS to uniquely identify the NetScaler (ADC/SVM) deployment.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To use the host name instead of the system identifier (`lsguid`), manually select the **Use hostname for LAS activation blob workflow** option from the NetScaler GUI

To activate the host name for LAS activation

1. Navigate to **System > Licenses > LAS Activation**.
2. Turn the **Use hostname for LAS activation blob workflow** toggle ON.



Best practices for monitoring your LAS transitioned NetScaler environment

This document focuses on the best practices that you can follow to monitor your NetScaler environments that use LAS. This document applies to deployments that use LAS with NetScaler ADC form factors: VPX (excluding VPX on SDX), MPX, and BLX having the Fixed Capacity Subscription license type.

Prerequisites

- Read the LAS for NetScaler page, including the FAQs for LAS with NetScaler ADC.
- Read the License Activation Service and complete your LAS migration.
- Ensure that you set up the relevant notifications, and monitor the NetScaler GUI and CLI regularly.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

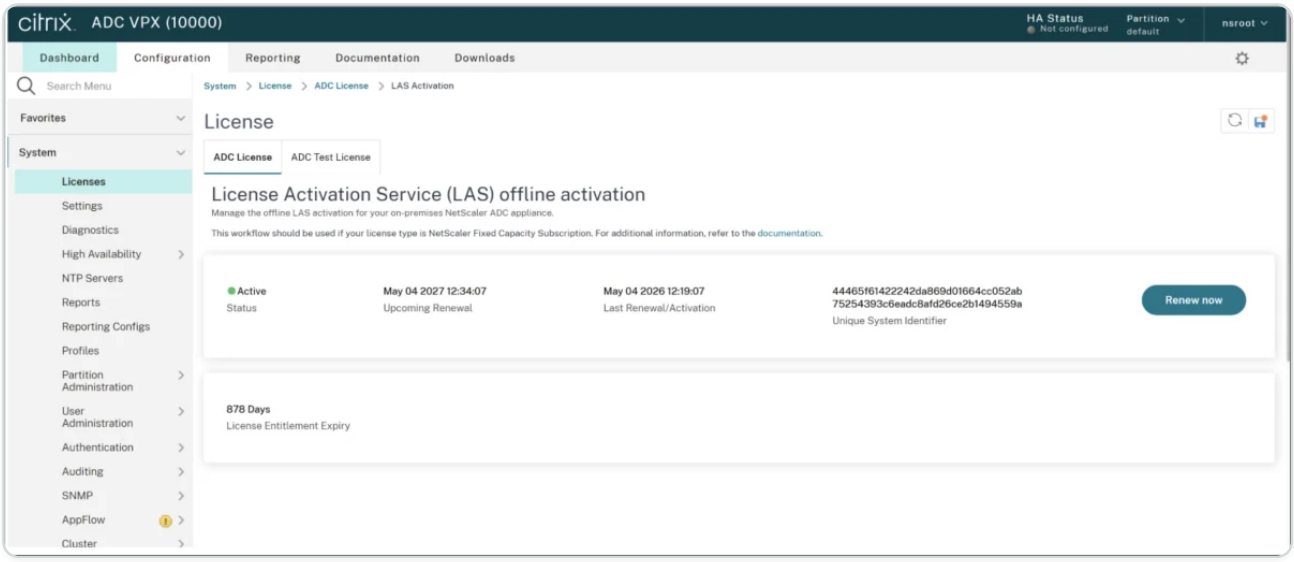
We intend to make continuous improvements to notifications and keep this documentation updated accordingly.

Monitoring LAS activation blob expiry

You can use the NetScaler ADC GUI and CLI to track your LAS activation blob expiry and avoid unexpected license interruptions.

NetScaler ADC GUI:

Navigate to **ADC GUI > Configuration > System > Licenses > LAS Offline Activation > ADC Licenses**, and monitor your **Upcoming Renewal**.



NetScaler ADC CLI:

You can use the `show ns laslicense` command and refer to the value of the `Renewalnextdate` parameter.

Sample:

```
show ns laslicense

         Status:  ACTIVE

DaysToExpiration:  878

Renewalprev:  1777877347 Renewalnext:  1809414247
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        Renewalprevdate:  Mon May  4 00:49:07 2026

        Renewalnextdate:  Tue May  4 01:04:07 2027

Done
```

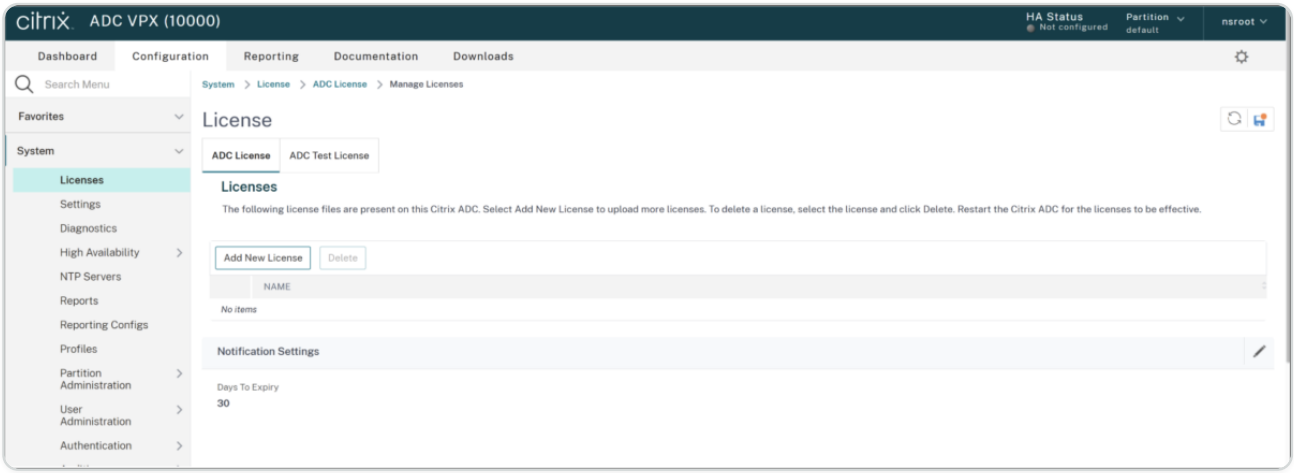
Notifications

Banner on NetScaler ADC GUI:

This banner on the NetScaler ADC GUI is triggered by the NetScaler instance when LAS activation blob expiry is upcoming in less than 30 days. It appears on the GUI every time a user logs in.

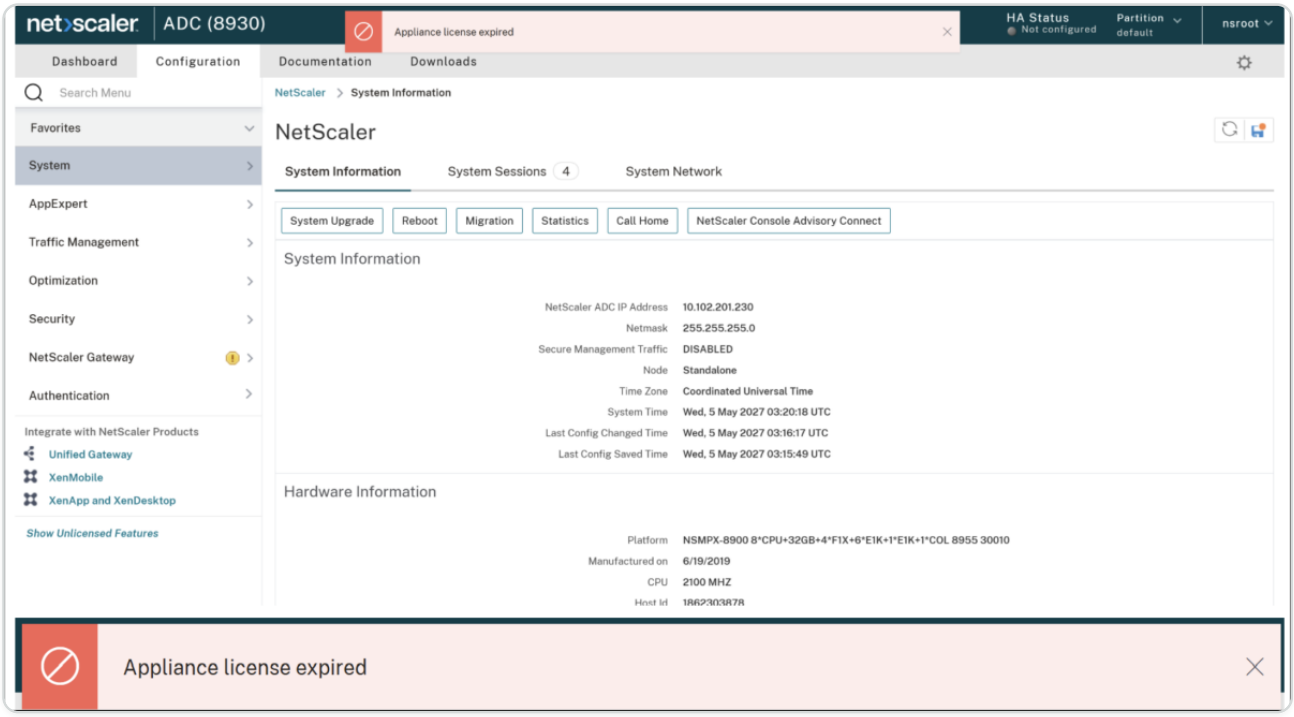
You can configure this setting to appear "x" days before expiry. The default is 30 days before expiry.

To configure this setting, navigate to **ADC GUI > Configuration > System > Licenses > ADC Licenses > Notification Settings**, and click the **Pencil** icon to edit the details.



A similar banner is shown if the LAS activation blob has expired.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



SNMP-based notification

SNMP trap for upcoming LAS activation blob expiry:

The SNMP trap is named `nsLicenseExpiry`. This SNMP trap is triggered by a NetScaler instance when the LAS activation blob expiry is upcoming in less than 30 days. This trap is generated every 24 hours, starting 30 days before LAS activation blob expiry, and continues until the blob is expired.

You can configure your SNMP manager to recognize this SNMP alarm and set up notifications as needed.

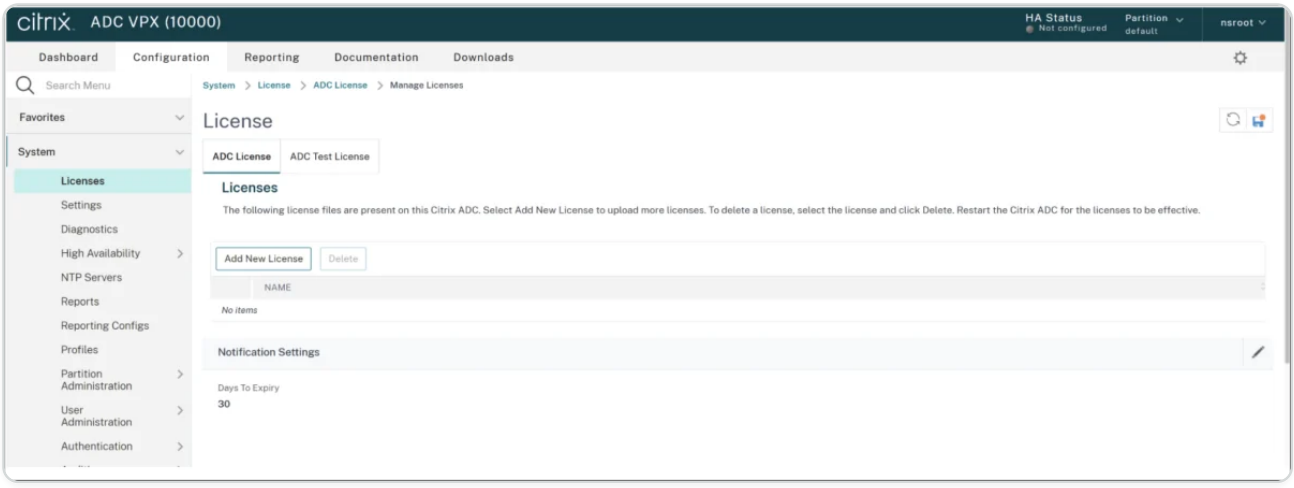
Sample:

```
May 5 23:30:14 <local0.info> 10.102.201.33 05/06/2026:05:30:14 GMT 0-
PPE-2 : default SNMP TRAP_SENT 0 0 : nsLicenseExpiry (nsPartitionName =
default)
```

You can configure this SNMP alarm to be triggered from `x` days before expiry. The default is 30 days before LAS activation blob expiry.

To configure this setting, navigate to **ADC GUI > Configuration > System > Licenses > ADC Licenses > Notification Settings** and click the **Pencil** icon to edit the details.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



SNMP for LAS activation blob already expired:

The SNMP trap is named `nsLicenseExpired`. This SNMP trap is triggered by a NetScaler instance when the LAS activation blob has expired.

You can configure your SNMP manager to recognize this SNMP alarm and set up notifications as needed.

Sample:

```
May 12 01:03:48 <local0.info> 10.102.201.33  05/12/2026:07:03:48 GMT  0-PPE-2 : default SNMP TRAP_SENT 0 0 :  nsLicenseExpired (nsPartitionName = default)
```

Syslog-based notification

Syslog for LAS activation blob upcoming expiry:

A syslog is triggered by a NetScaler instance when the LAS activation blob expiry is upcoming in less than 30 days. This trap is generated every 24 hours, starting 30 days before LAS activation blob expiry, and continues until the blob is expired.

You can set up your syslog manager to recognize this syslog and set up notifications as needed.

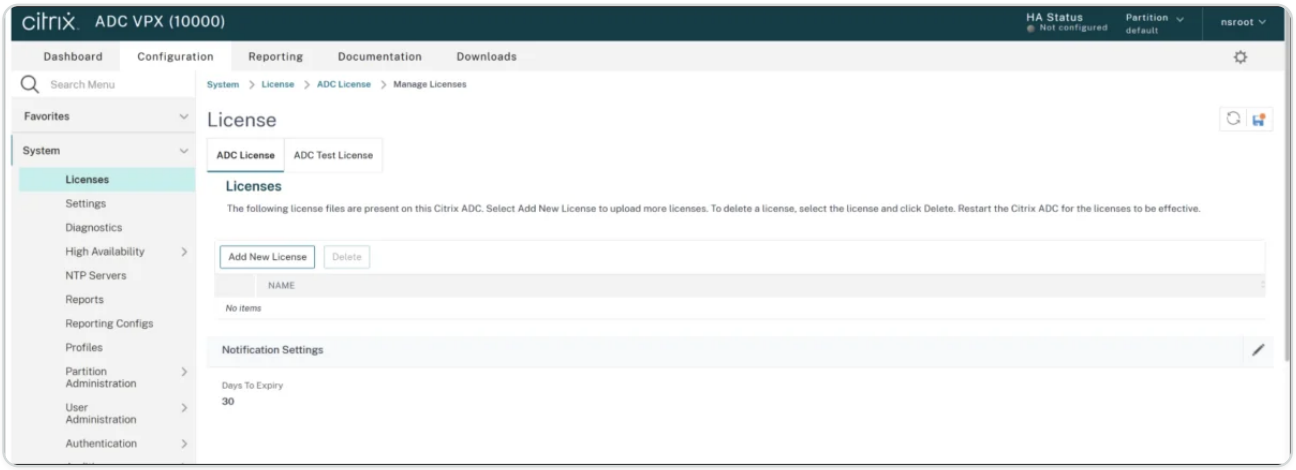
Sample:

```
May  5 23:30:14 <local0.crit> ns nsnetsvc[97782]: nscfe_licenseexp_timer_handler(): Some licenses are expiring in 19 days. Please ensure timely renewal and apply the license to ensure uninterrupted functioning
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

You can configure the syslog to be triggered from `x` days before expiry. The default is 30 days before LAS activation blob expiry.

To configure this setting, navigate to **ADC GUI > Configuration > System > Licenses > ADC Licenses > Notification Settings** and click the **Pencil** icon to edit the details.



Syslog for LAS activation blob already expired:

A syslog is triggered by a NetScaler instance when the LAS activation blob has reached an expired state (that is, 0 days to expiry). You can set up your syslog manager to recognize this syslog and set up notifications as needed.

Sample:

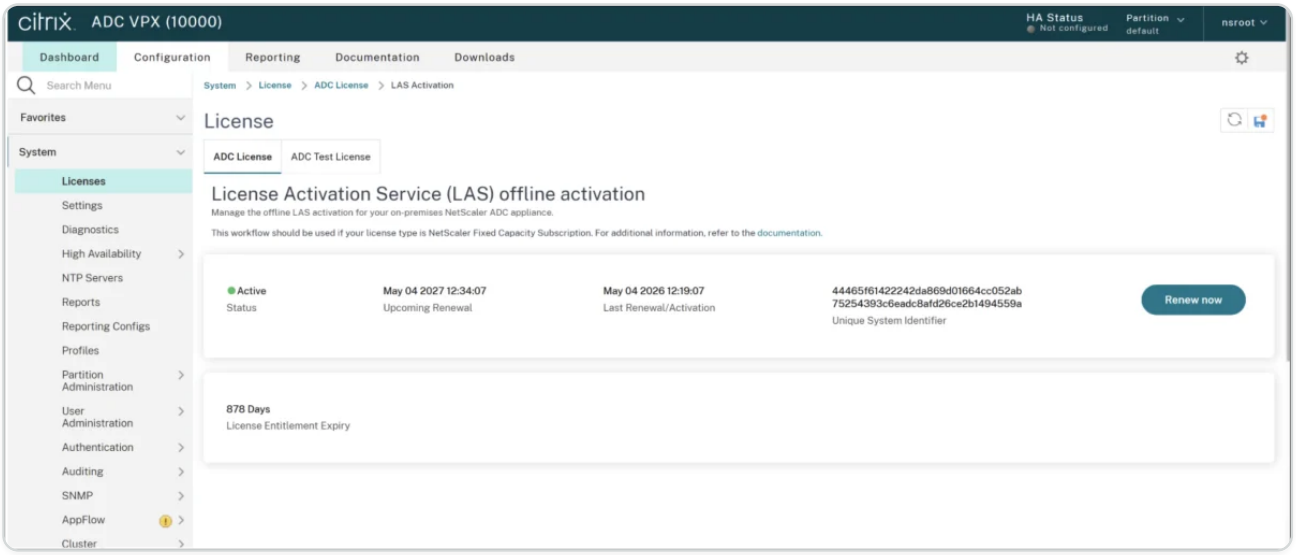
```
May 12 01:03:48 <local0.crit> ns nsnetsvc[94684]:
nscfe_licenseexp_timer_handler(): License expired, system will be
unlicensed now. Rebooting the system...
```

Monitoring license entitlement expiry (contract expiry)

NetScaler ADC GUI:

Navigate to **ADC GUI > Configuration > System > Licenses > LAS Offline Activation > ADC Licenses** and monitor your **License Entitlement Expiry**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



NetScaler ADC CLI:

You can use the `show ns laslicense` command and refer to the value of the `DaysToExpiration` parameter.

Sample:

```
show ns laslicense

         Status:  ACTIVE

DaysToExpiration:  878

Renewalprev:  1777877347 Renewalnext:  1809414247

       Renewalprevdate:  Mon May  4 00:49:07 2026

       Renewalnextdate:  Tue May  4 01:04:07 2027

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Allocate and apply a license

IMPORTANT:

File-based licensing system (also referred to as manually managed entitlements), traditionally used for activating various on-premises components, will be End of Life (EOL) on April 15, 2026. License Activation Service (LAS) is the next generation technology for product activations across the suite of Citrix products. LAS will be the only way to activate and license NetScaler instances after April 15, 2026, supporting NetScaler Flexed licenses (CPL/UHMC), legacy NetScaler Pooled licenses, and NetScaler Fixed term Bandwidth licenses. To remain supported, your NetScaler and NetScaler Console deployments must be on a LAS compatible version.

The minimum required NetScaler® versions that are LAS compatible are:

- NetScaler ADCs: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS), 14.1-66.68 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x
- NetScaler Console Service: Supported from early September 2025
- NetScaler Console on-prem: 14.1-51.x

  Note: LAS support for Console on-prem is from release 14.1-51.x onwards. However, file-based licensing is deprecated as of April 15 2026 from Console on-prem releases 14.1-51.x onwards and 13.1-60.x onwards. If you upgrade to Console on-prem release 14.1-51.x or release 13.1-60.x or later, you can continue using file-based licensing until 15th April 2026. However you must upgrade to Console on-prem release 14.1-51.x or later, and switch to LAS before 15th April 2026 because Console on-prem 13.1 does not support LAS.

All the other forms of legacy NetScaler licenses such as Pooled vCPU, CICO, perpetual will not be supported with LAS. NetScaler instances leveraging perpetual licenses without an active maintenance will become unlicensed upon upgrade to the above mentioned software versions.
LAS based licenses may not be available to customers where prohibited by law or regulations.
If you have questions or concerns, contact Customer Care. Citrix® may limit or suspend your Citrix Maintenance for non-compliance with these requirements without liability in addition to any other remedies Citrix may have at law or equity. These requirements don’t apply where prohibited by law or regulation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

File-based licensing

NOTE:

The following sections are applicable for File-based licensing and does not apply to License Activation Service (LAS).

In the NetScaler MPX and VPX ADC GUI, you can use your hardware serial number (HSN) or your license access code to allocate your licenses. Alternatively, if a license is already present on your local computer, you can upload it to the appliance.

For all other functionality, such as returning or reallocating your license, you must use the licensing portal. Optionally, you can still use the licensing portal for license allocation. For more information, see Manage Licenses.

Citrix Licensing guide

The Citrix Licensing guide also covers information about installing licenses in a NetScaler appliance and installing licenses in other NetScaler products. For more information, see the NetScaler Licensing Guide.

Prerequisites

NOTE:

Buy separate licenses for each appliance in a high availability pair. Ensure that the same types of licenses are installed on both the appliances. For example, if you buy a premium license for one appliance, you must purchase another premium license for the other appliance.

To use the hardware serial number or license access code to allocate your licenses:

- You must be able to access public domains through the appliance. For example, the appliance must be able to access `<www.citrix.com>`. The license allocation software internally accesses the Citrix licensing portal for your license. To access a public domain:
  - Use a proxy server or set up a DNS server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Configure a NetScaler IP (NSIP) address or a subnet IP (SNIP) address on your NetScaler appliance.

- Your license must be linked to your hardware, or you must have a valid license access code. Citrix sends your license access code by email when you purchase a license.

Allocate a license by using the GUI

If your license is already linked to your hardware, the license allocation process can use the hardware serial number. Otherwise, you must type the license access code.

You can partially allocate licenses as required for your deployment. For example, if your license file contains 10 licenses, but your current requirement is for only six licenses, you can allocate six licenses now, and allocate more licenses later. You can’t allocate more than the total number of licenses present in your license file.

To allocate your license

1. In a web browser, type the IP address of the NetScaler appliance (for example, `http://192.168.100.1`).
2. In User Name and Password, type the administrator credentials.
3. On the **Configuration** tab, navigate to **System > Licenses**.
4. In the details pane, click **Manage Licenses**, click **Add New License**, and then select one of the following options:

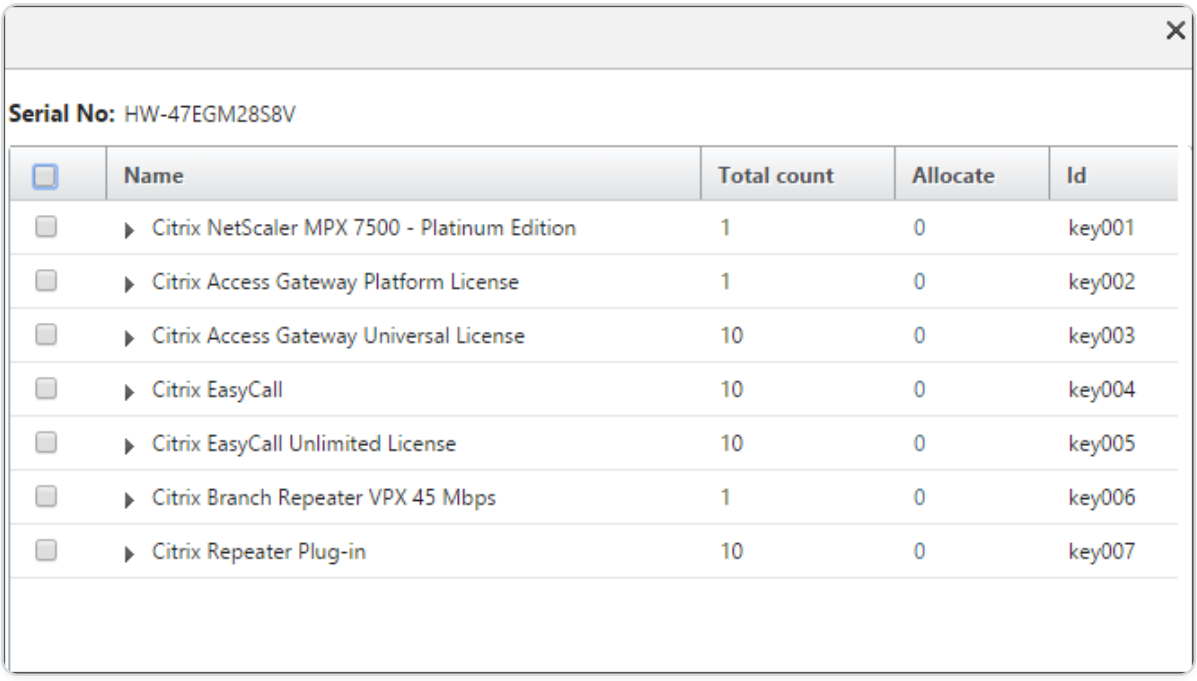
    - **Use Serial Number**: The software internally fetches the serial number of your appliance and uses this number to display your licenses.
    - **Use license access code**: Citrix emails the license access code for the license that you purchased. Enter the license access code in the text box.

      If you do not want to configure internet connectivity on the NetScaler appliance, you can use a proxy server. Select **Connect through Proxy Server** and specify the IP address and port of your proxy server.

5. Click **Get Licenses**. Depending on the option that you selected, one of the following dialog boxes appears.

    - The following dialog box appears if you selected Hardware Serial Number.

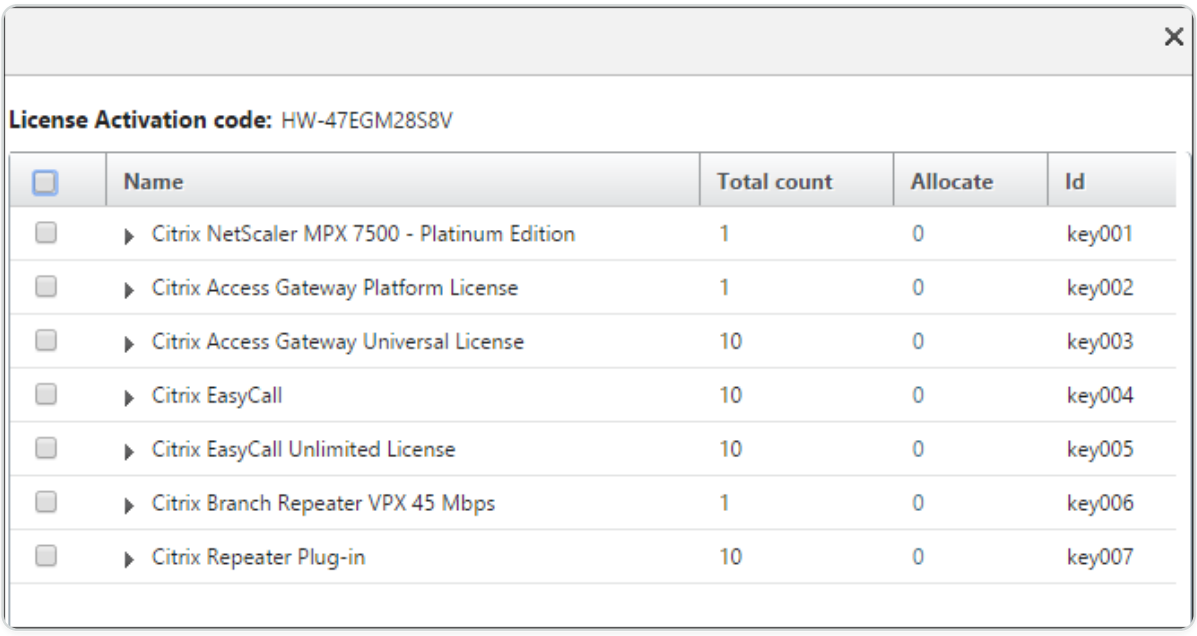
© 1997–2026 Citrix Systems, Inc. All rights reserved.



Serial No: HW-47EGM28S8V

Name	Total count	Allocate	Id
Citrix NetScaler MPX 7500 - Platinum Edition	1	0	key001
Citrix Access Gateway Platform License	1	0	key002
Citrix Access Gateway Universal License	10	0	key003
Citrix EasyCall	10	0	key004
Citrix EasyCall Unlimited License	10	0	key005
Citrix Branch Repeater VPX 45 Mbps	1	0	key006
Citrix Repeater Plug-in	10	0	key007

- The following dialog box appears if you selected License Access Code.



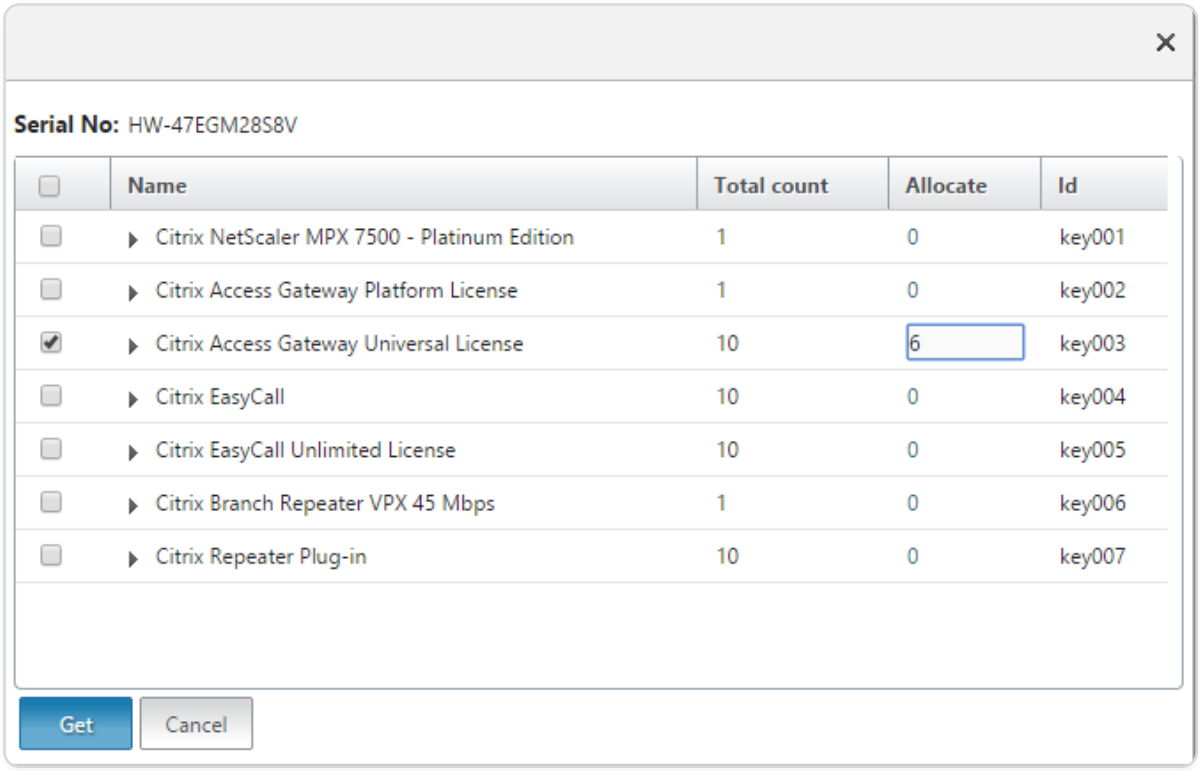
License Activation code: HW-47EGM28S8V

Name	Total count	Allocate	Id
Citrix NetScaler MPX 7500 - Platinum Edition	1	0	key001
Citrix Access Gateway Platform License	1	0	key002
Citrix Access Gateway Universal License	10	0	key003
Citrix EasyCall	10	0	key004
Citrix EasyCall Unlimited License	10	0	key005
Citrix Branch Repeater VPX 45 Mbps	1	0	key006
Citrix Repeater Plug-in	10	0	key007

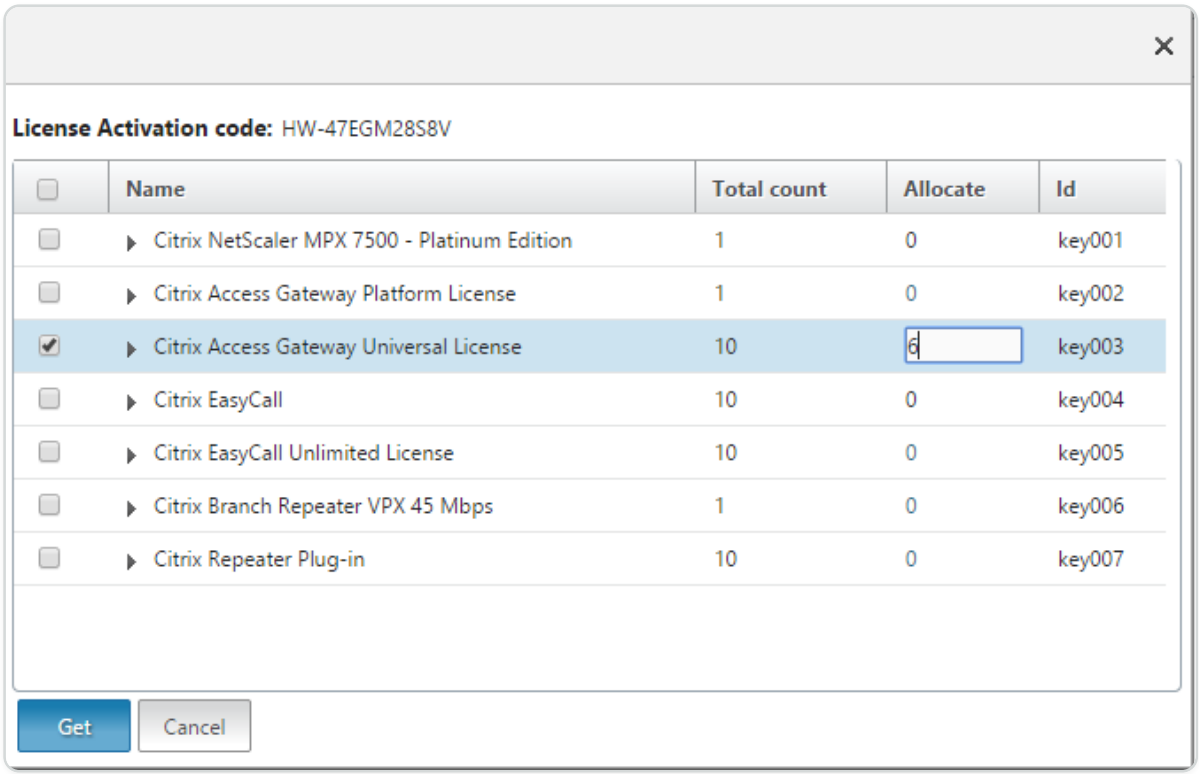
6. Select the license file that you want to use to allocate your licenses.
7. In the **Allocate** column, enter the number of licenses to be allocated. Then click **Get**.

    - If you selected **Hardware Serial Number**, enter the number of licenses, as shown in the following screenshot.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

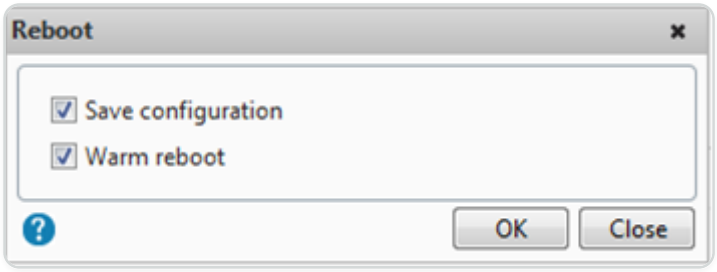


- If you selected **license access code**, enter the number of licenses, as shown in the following screenshot.



8. Click **Restart** for the license to take effect.
9. In the restart dialog box, click **OK** to proceed with the changes, or click **Close** to cancel the changes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Install a license

If you downloaded your license file to your local computer by accessing the licensing portal, you must upload the license to the appliance.

To install a license file by using the GUI

1. In a web browser, type the IP address of the NetScaler appliance (for example, `http://192.168.100.1`).
2. In User Name and Password, type the administrator credentials.
3. On the **Configuration** tab, navigate to System Licenses.
4. In the details pane, click **Manage Licenses**.
5. Click **Add New License**, then select **Upload license files from a local computer**.
6. Click **Browse**. Navigate to the location of the license files, select the license file, and then click **Open**.
7. Click restart to apply the license.
8. In the restart dialog box, click **OK** to proceed with the changes, or click **Close** to cancel the changes.

To install the licenses by using the CLI

1. Open an **SSH connection** to the ADC appliance by using an SSH client, such as PuTTY.
2. Log on to the ADC appliance by using the administrator credentials.
3. Switch to the shell prompt, create a license subdirectory in the `nsconfig` directory, if it does not exist, and copy one or more new license files to this directory.

   Example

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
login: nsroot

Password: nsroot

Last login: Mon Aug  4 03:37:27 2008 from 10.102.29.9

Done

> shell

Last login: Mon Aug  4 03:51:42 from 10.103.25.64

root@ns# mkdir /nsconfig/license

root@ns# cd /nsconfig/license
```

Copy one or more new license files to this directory.

NOTE

The NetScaler appliance does not prompt for a reboot option when you use the command line interface to install the licenses. Run the reboot -w command to warm restart the system, or run the restart command to restart the system normally.

Verify licensed features

Before using a feature, ensure that your license supports the feature.

To verify the licensed features by using the CLI

1. Open an **SSH connection** to the ADC appliance by using an SSH client, such as PuTTY.
2. Log on to the ADC appliance by using the administrator credentials.
3. At the command prompt, enter the sh ns license command to display the features supported by the license.

   Example

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
sh ns license

        License status:

                          Web Logging: YES

                     Surge Protection: YES

                       .......

                       Responder: YES

 Done
```

To verify the licensed features by using the GUI

1. In a web browser, type the IP address of the ADC appliance, such as `http://192.168.100.1`.
2. In User Name and Password, type the administrator credentials.
3. Provide the User name and Password and click **Login**.
4. In the navigation pane, expand **System**, and then click **Licenses**. You see a green check mark next to the licensed features.

Enable or disable a feature

When you use the NetScaler appliance for the first time, you must enable a feature before you can use its functionality. If you configure a feature before it's enabled, a warning message appears. The configuration is saved but it applies only after the feature is enabled.

To enable a feature by using the CLI

At the command prompt, type the following commands to enable a feature and verify the configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-  enable feature <FeatureName>

-  show feature
```

Example:

```
    enable feature lb cs

    done

     >show feature

           Feature                        Acronym             Status

           -------                        -------             ------

     1)    Web Logging                    WL                  OFF

     2)    Surge Protection               SP                  ON

     3)    Load Balancing                 LB                  ON

     4)    Content Switching              CS                  ON

     5)    Cache Redirection              CR                  ON

     .

     .

     .

     24)   NetScaler Push                 push                OFF

     Done
```

The example shows how to enable load balancing and content switching.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If the license key isn't available for a particular feature, the following error message appears for that feature:

ERROR: features not licensed

NOTE:

To enable an optional feature, you must have a feature-specific license. For example, you've purchased and installed the NetScaler Advanced Edition license. However, to enable the Integrated Caching feature, you must purchase and install the AppCache license.

To disable a feature by using the CLI

At the command prompt, type the following commands to disable a feature and verify the configuration:

```
-  disable feature \<FeatureName\>

-  show feature
```

Example:

The following example shows how to disable load balancing.

```
    > disable feature lb

     Done

    > show feature

           Feature                      Acronym            Status

           -------                      -------            ------

     1)    Web Logging                  WL                 OFF

     2)    Surge Protection             SP                 ON
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    3)     Load Balancing                LB                  OFF

    4)     Content Switching             CS                  ON

    .

    .

    .

    24)    NetScaler Push                push                OFF

    Done

   >
```

Configure NetScaler license expiry alerts

By default, a GUI alert appears when the ADC license expiry date is less than or equal to 30 days.

You can configure the NetScaler appliance to perform the following alert operations from a specified number of days before a NetScaler license is due to expire:

- Display a license expiry alert banner on the NetScaler GUI.
- Send SNMP traps containing the license expiry information at regular intervals to the configured trap listeners if the "NS_LICENSE_EXPIRY" SNMP alarm is enabled.

Upon license expiry, the NetScaler appliance automatically restarts to revoke the license. If a NetScaler appliance uses Citrix service provider (CSP) licenses, the appliance does not restart automatically to revoke the license. However, if the user restarts the appliance, it restarts as unlicensed.

To specify a number of days for NetScaler license expiry alerts by using the CLI:

At the command prompt, type:

- **set licenseparameters**
- **sh licenseparameters**

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> set licenseparameters -licenseexpiryalerttime 200

Done

> sh licenseparameters

...

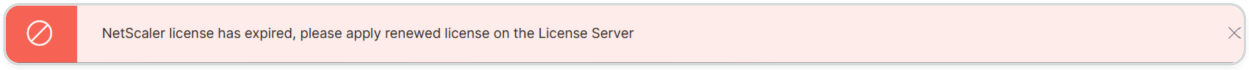
    Licenseexpiryalerttime:  200
```

To specify a number of days for NetScaler license expiry alerts by using the NetScaler GUI:

1. Navigate to **Configuration** > **System** > **Licenses** > **Manage Licenses**.
2. In **Notification Settings**, click the edit button to specify a number of days for NetScaler license expiry alerts.

The following license expiry alerts are displayed depending on the condition met:

- After license expiry



- License nearing expiration and crosses the specified number of days before a NetScaler license is due to expire

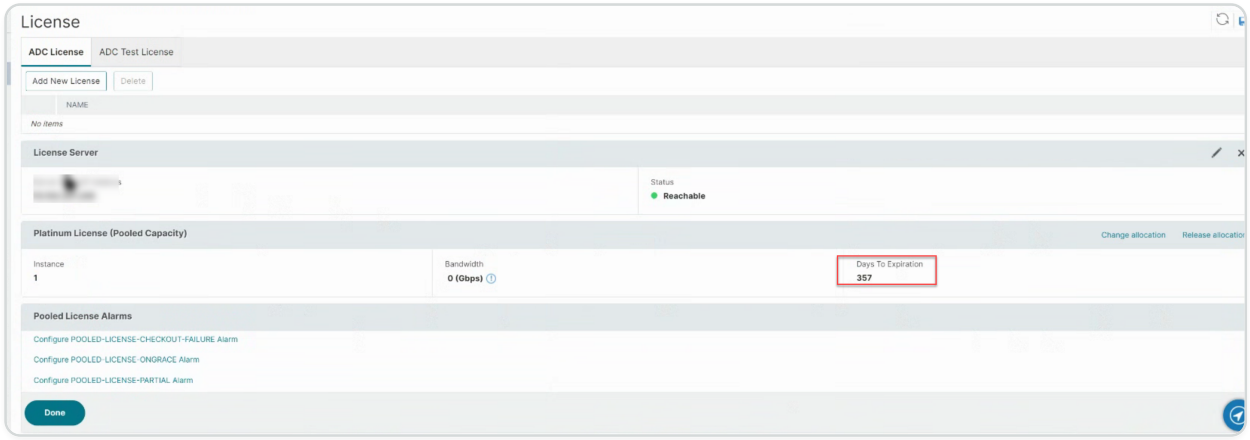
Check license expiry information

You can check NetScaler license expiry information through the GUI or CLI.

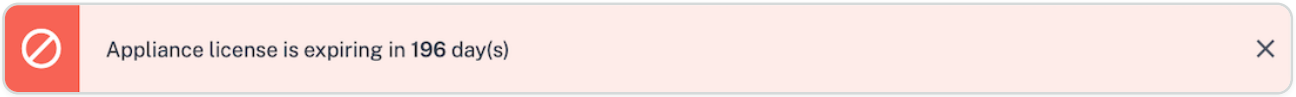
To check NetScaler license expiry information through GUI:

- Go to **Configuration > System > Licenses**.
- For Flexed/Pooled license, go to **Configuration > System > Licenses > Manage Licenses**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



A GUI alert appears when the ADC license expiry date is less than or equal to the specified number of days for the NetScaler license expiry alert.



To check the license expiry information through CLI:

Type the command "show ns license".

```
> sh license

    License status:

    Web Logging: YES

    Surge Protection: YES

    Web Logging: YES

    Surge Protection: YES

    …

Days to expiry: 196
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

>
```

Validate license files without rebooting the NetScaler appliance

With this feature, you can test licenses and see all the features available in the given license without applying them on the NetScaler appliance. This option allows you to test new licenses without rebooting the NetScaler appliance.

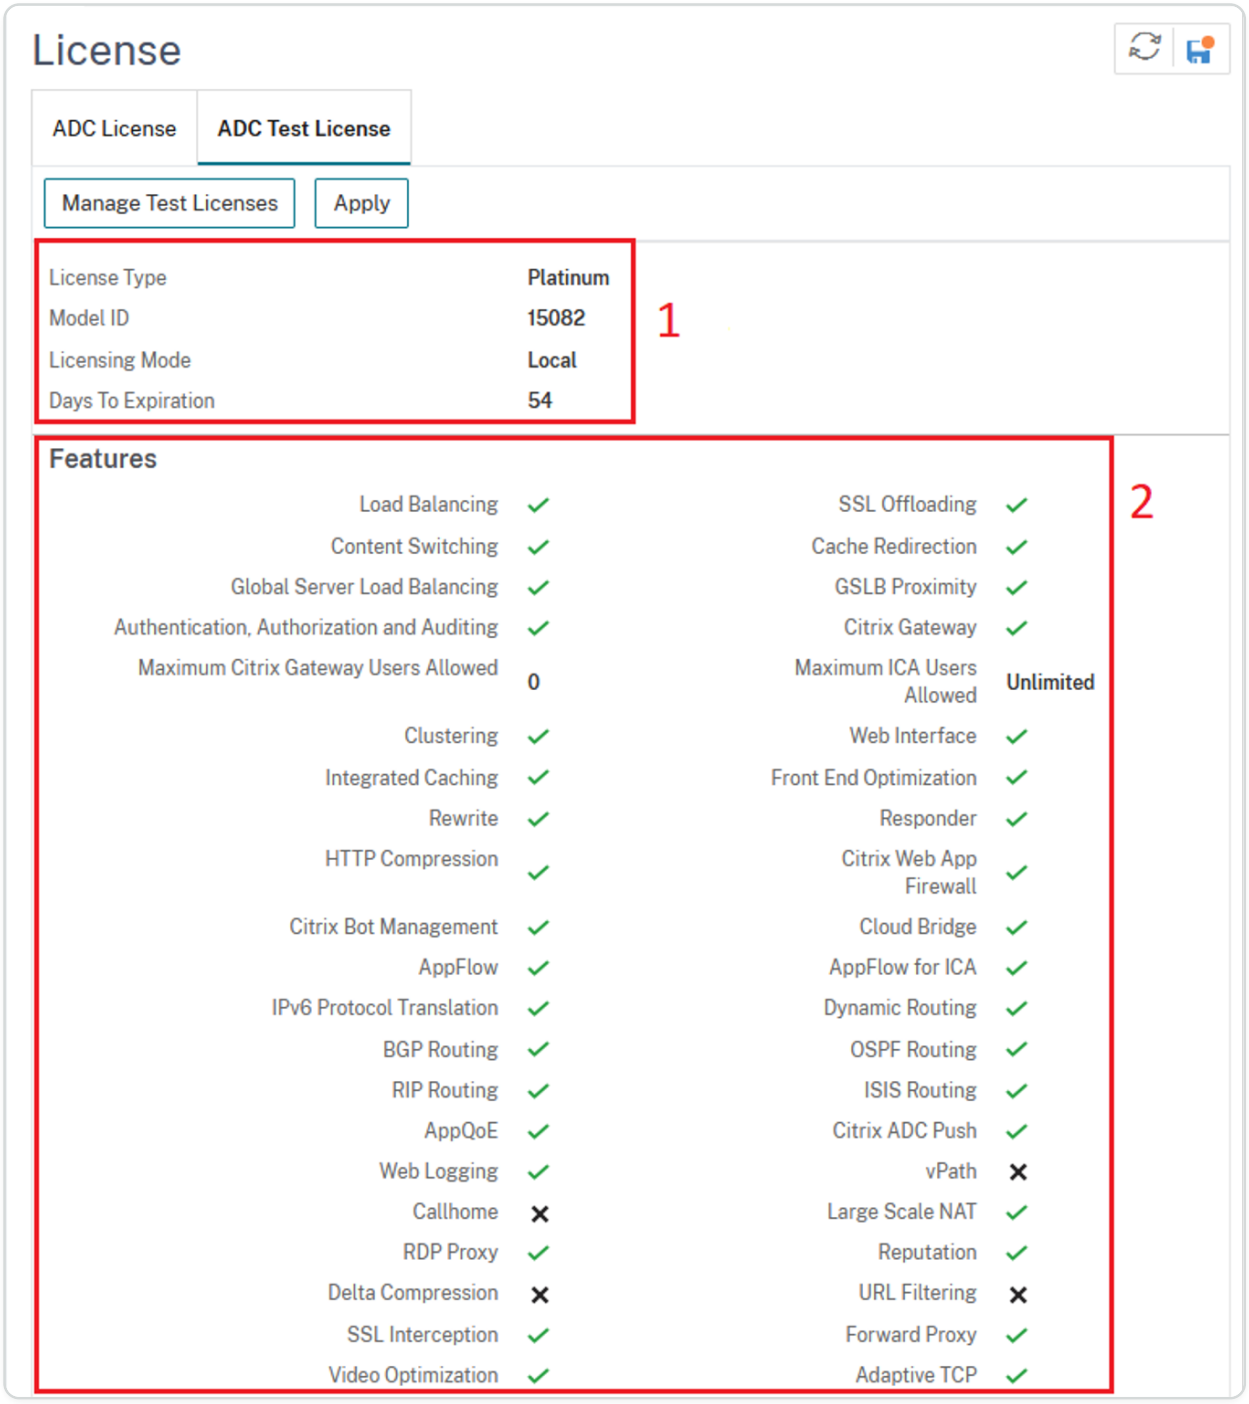
You can use this feature by both GUI and CLI.

Validate license files by using the GUI

1. Go to **System -> Licences**.
2. In the **ADC Test License** tab, click **Manage Test Licenses**.
3. Click **Upload**, and upload one or more license files. If multiple license files are uploaded, the union of all license files is calculated.
4. After the license file upload is complete, click **ADC Test License** again to display the licensed features of the uploaded license.

   Section 1 shows license information and Section 2 shows all features that the license includes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Verify the information displayed and click **Apply** to use the license. Reboot (warm) the NetScaler appliance for the license to take effect. Immediate reboot isn't mandatory, and the current license is applicable until the next reboot.

Validate license files by using the CLI

1. Copy the test license file to the ADC appliance at path: `/nsconfig/testlicense`.

   Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
scp CNS_15082_SERVER_PLT_Retail.lic nsroot@<ns_ip>:/nsconfig/
testlicense/
```

2. Verify whether the license file is copied to the correct location.

   Example:

```
ls /nsconfig/testlicense/  CNS_15082_SERVER_PLT_Retail.lic
```

3. Run the `show ns testlicense` command to see the license information.

```
> sh ns testlicense

    License status:

                      Web Logging: YES

                Surge Protection: YES

                  Load Balancing: YES

               Content Switching: YES

               Cache Redirection: YES

             Compression Control: YES

               Delta Compression: NO

                  SSL Offloading: YES

      Global Server Load Balancing: YES

                             .....

                     API Gateway: YES

                Model Number ID: 15082

                   License Type: Platinum License

                  Licensing mode: Local
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                Days to expiration: 54
```

4. Verify the information displayed, and run the `apply ns testlicense` command to apply the license. Reboot (warm) the NetScaler appliance for the license to take effect.

```
> apply ns testlicense

Warning: The configuration changes will not take effect until the
system is rebooted

Done

> reboot -w

Are you sure you want to restart NetScaler (Y/N)? [N]:Y

Done
```

Upgrade a license

Edition and bandwidth upgrades aren't supported. To move between editions in a pooled subscription, you must purchase a new pooled subscription with the new edition and upload those licenses to {{page:adm-product-name-short}}.

Bandwidth upgrade does not apply to pooled licenses because each instance can check-in/check-out the necessary bandwidth based on the requirement as long as the underlying hardware or software supports it.

NOTE:

You can use {{page:adm-product-name-long}} to create a licensing framework that comprises a common bandwidth and instance pool. For complete information, see NetScaler pooled capacity.

Data governance

What is Console Advisory Connect?

Console Advisory Connect is a feature to enable seamless onboarding of NetScaler MPX, SDX, and VPX instances, and NetScaler Gateway appliances onto NetScaler Console service. This feature lets the NetScaler instance or NetScaler Gateway appliance automatically, securely connect with NetScaler Console service, and send system, usage, and telemetry data to it. Based on this data, you get insights and recommendations for your NetScaler infrastructure on NetScaler Console service.

By using the Console Advisory Connect feature and onboarding your NetScaler instances or NetScaler Gateway appliances to NetScaler Console service. You can also manage all your NetScaler and NetScaler Gateway assets whether on-premises or in the cloud. Also, you benefit from access to a rich set of visibility features that help in quick identification of performance issues, high resource usage, critical errors, and so on. NetScaler Console service provides a wide range of capabilities for your NetScaler instances and applications. For more information on NetScaler Console service, see NetScaler Application Delivery Management Service

IMPORTANT

- NetScaler Gateway appliance also supports the Console Advisory Connect feature. For better ease, the NetScaler Gateway appliance isn't called explicitly in the consecutive sections.

What is NetScaler Console service?

NetScaler Console service is a cloud-based solution that helps you manage, monitor, orchestrate, automate, and troubleshoot your NetScaler instances. It also provides you analytical insights and curated machine learning based recommendations about NetScaler instances and about

© 1997–2026 Citrix Systems, Inc. All rights reserved.

application health, performance, and security. For more information, see NetScaler Console service Overview

How the Console Advisory Connect is enabled?

Console Advisory Connect is enabled by default, after you install or upgrade NetScaler or Gateway to release 13.0 build 61.xx and above.

What data is captured using Console Advisory Connect?

The following details are captured using Console Advisory Connect:

- **NetScaler details**
  - Serial ID
  - Encoded Serial ID
  - Host ID
  - UUID
  - Management IP address
  - Host name
  - Version
  - Build type
  - Build
  - License type
  - Hypervisor
  - Deployment type(standalone/HA)
  - Platform type
  - Platform description

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- System ID
- Modes enabled on ADC
- Features enabled on ADC

- **License Information**
  - Features licensed on NetScaler
  - License number
- **Key usage metrics**
  - System date time
  - CPU usage percentage
  - Management CPU percentage
  - Throughput
  - SSL new sessions
  - SSL encryption throughput
  - SSL decryption throughput
  - System Uptime
- **Configuration**
  - ns.conf file

> **NOTE**
>
> Before the Console Advisory Connect sends the `ns.conf` file from NetScaler appliance to the NetScaler Console service, it anonymizes the encrypted or hashed passwords. The Console Advisory Connect checks for `-encrypted` or `-passcrypt` parameters and replaces the associated encrypted or hashed value with `XXXX`. The Console Advisory Connect then encodes and compresses the `ns.conf` file, and sends it to the NetScaler Console service endpoint.

- **Critical error details**
  - Hard disk failures
  - SSL card failures

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Power Supply Unit (PSU) failures
- Flash drive failure
- Warm reboot
- Sustained memory usage above 90% or a memory leak
- Sustained rate limit drops

- **Usage of NITRO automation tools**
  - Usage of automation tools such as Ansible, Terraform, or NITRO SDKs.
- **Diagnostics details**

  Note:

  > The ADM diagnostic tool uses the following diagnostic details. For more information, see the Diagnostic tool topic in NetScaler Console.

  - ADC CLI status
  - ADC DNS status
  - network connection status to ADM endpoint "adm.cloud.com"
  - network connection status to ADM endpoint "agent.adm.cloud.com"
  - network connection status to ADM trust service "trust.citrixnetworkapi.net"
  - network connection status to ADM download site "download.citrixnetworkapi.net"

How the data is used?

By collecting the data, NetScaler can provide you with timely and in-depth insights about your NetScaler installations, which include the following:

- **Key metrics**. Details of key metrics about CPU, memory, throughput, SSL throughput, and highlight anomalous behavior on NetScaler instances.
- **Critical errors**. Any critical errors that might have occurred on your NetScaler instances.
- **Deployment advisory**. Identify NetScaler instances that are deployed in standalone mode but have high throughput and are vulnerable to a single point of failure.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Diagnostic tool**. When you onboard an ADC instance onto NetScaler Console, you might experience a few issues that prevent the ADC instance from successfully onboarding. To troubleshoot the issues, you can either manually use the diagnostic tool or see the diagnostic information in the ADM GUI. For more information, see Diagnostic tool.

How long the collected data is kept?

Any data collected is kept for no longer than 13 months.

If you decide to terminate the use of the service by disabling the Console Advisory Connect feature from the NetScaler, any previously collected data is deleted after a period of 30 days.

Where the data is stored and how secure is it?

All data collected by Console Advisory Connect is stored in one of the three regions–United States, European Union, and Australia and New Zealand (ANZ). For more information, see Geographical Considerations.

The data is stored securely with strict tenant isolation at the database layer.

How to disable Console Advisory Connect?

If you want to disable data collection through Console Advisory Connect, see How to enable and disable Console Advisory Connect.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Introduction to Console Advisory Connect for NetScaler appliances

NetScaler Console service is a cloud-based solution that helps you manage, monitor, orchestrate, automate, and troubleshoot your NetScaler instances. It also provides analytical insights and curated machine learning based recommendations for your applications health, performance, and security. For more information, see NetScaler Application Delivery Management Service.

Console Advisory Connect is a feature to enable seamless onboarding of NetScaler instances onto NetScaler Console service. This feature helps NetScaler instances and NetScaler Console service to function as a holistic solution, which offers customers multi fold benefits.

Console Advisory Connect feature lets the NetScaler instance automatically connect with the NetScaler Console service and send system, usage, and telemetry data to it. Based on this data, the NetScaler Console service gives you some insights and recommendations on your NetScaler and Gateway infrastructure like the following:

- Security advisory insight highlighting your vulnerable ADC appliances.
- Upgrade advisory insight highlighting ADC appliances that have reached or about to reach end of maintenance and end of life.
- Quick identification of performance issues, high resource usage, and critical errors.

To harness the power of NetScaler Console service, you can choose to onboard your NetScaler instances to NetScaler Console service. The onboarding process uses Console Advisory Connect, and makes the experience smooth and faster for you.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

POINTS TO NOTE

- Console Advisory Connect is now available on NetScaler MPX, SDX, and VPX instances and NetScaler Gateway appliances.
- The initiative in NetScaler Console service that uses this Console Advisory Connect feature is Console Advisory Connect based low-touch onboarding. For more information, see Low-touch onboarding of NetScaler instances using Console Advisory Connect.
- If Console Advisory Connect is enabled on an ADC instance, certain diagnostic details are automatically sent to ADM service.

For more information, see Data governance.

IMPORTANT

Console Advisory Connect fails to collect the probe data and cannot help in on-boarding the ADC appliance to ADM service if the following conditions are met:

- `NSinternal` user account is disabled.
- SSH public key is not set up.

To overcome the preceding scenario, Citrix® recommends you follow any one of the following:

- Enable `internaluser` user account by using the `set ns param –internaluserlogin ENABLED`.
- Configure the public key authentication. For more information, see Access a NetScaler appliance by using SSH keys and no password .

How does Console Advisory Connect support with NetScaler Console service?

Here is a high-level workflow of how the Console Advisory Connect feature on NetScaler interacts with NetScaler Console service.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Console Advisory Connect feature on NetScaler appliance auto connects with NetScaler Console service using a periodic probe request.
2. This request has system, usage and telemetry data, using which the NetScaler Console service gives you some insights and recommendations on your NetScaler infrastructure. Like; quick identification of performance issues, high resource usage, and critical errors.
3. You can view the insights and recommendations and decide to onboard your ADC instances to the NetScaler Console service to start managing your NetScaler instances.
4. When you decide to onboard, the Console Advisory Connect feature helps complete the onboarding seamlessly.

What versions of NetScaler is Console Advisory Connect supported on?

Console Advisory Connect is supported on all NetScaler platforms and all appliance models (MPX, VPX, and SDX). Starting from NetScaler release 13.0 build 61.xx, Console Advisory Connect is enabled by default for NetScaler appliances.

How to enable Console Advisory Connect?

If you are an existing NetScaler customer, and upgrade to NetScaler release 13.0 build 61.xx, Console Advisory Connect is enabled by default as part of the upgrade process.

If you are a new NetScaler customer, installing NetScaler release 13.0 build 61.xx, Console Advisory Connect is enabled by default as part of the install process.

NOTE

Unlike the new NetScaler appliances, existing NetScaler appliances find the route through Citrix Insight Service (CIS) or Call Home.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How to enable and disable Console Advisory Connect?

You can enable and disable Console Advisory Connect from CLI, GUI, or NITRO API methods.

Using CLI

To enable the Console Advisory Connect by using the CLI

At the command prompt, type:

```
set adm parameter –admserviceconnect ENABLED
```

To disable the Console Advisory Connect by using the CLI

At the command prompt, type:

```
set adm parameter –admserviceconnect DISABLED
```

IMPORTANT

If your NetScaler is on release 13.0 build 61.xx, the parameter name to enable or disable Console Advisory Connect is "autoconnect." For example, to enable service connect, use the `set adm parameter – autoconnect ENABLED` command.

Using the GUI

To disable the Console Advisory Connect by using the NetScaler GUI

1. In a web browser, type the IP address of the NetScaler appliance (for example, `<http://192.0.2.10>`).
2. In **User Name** and **Password**, enter the administrator credentials.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Navigate to **System > Settings > Configure ADM Parameters**.
4. On the **Configure ADM Parameters** page, clear the **Enable Console Advisory Connect** dialog box, and click **OK**.

Using the NITRO API

You can disable Console Advisory Connect by using the **NITRO** command.

- In NetScaler release 13.0 build 61.xx, you can enable or disable the Console Advisory Connect by using the following command:
  - `curl –X PUT –H "Content-Type:application/json" http://192.0.2.10/nitro/v1/config/admparameter> -d '{"admparameter":{"autoconnect":"enabled"}}' -u nsroot:Test@1`
- From NetScaler release 13.0 build 64.xx, the "autoconnect" parameter name is renamed to `admserviceconnect`. You can disable the Console Advisory Connect by using the following command:
  - `curl –X PUT –H “Content-Type:application/json” http://192.0.2.10/nitro/v1/config/admparameter -d '{"admparameter":{"admserviceconnect":"disabled"}}' -u nsroot:Test@1`

Diagnostic tool

When you onboard an ADC instance onto NetScaler Console, you might experience a few issues that prevent the ADC instance from successfully onboarding. To troubleshoot the issues, you can either manually use the diagnostic tool or see the diagnostic information in the ADM GUI.

- For more information about the details captured using Console Advisory Connect, see Data governance.
- For more information about the diagnostic tool, see Diagnostic tool.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NetScaler Console built-in agent behavior

From NetScaler release 13.0 build 61.xx and higher, the NetScaler Console built-in agent available on NetScaler instances communicates with ADM service. It communicates without the need for manual initialization on the respective ADC instance. After communication with ADM service is established, the built-in agent stays evergreen by auto-upgrading itself to the latest software version regularly.

Previously, you had to initialize the built-in agent on the ADC instances, using `mastools` commands, to establish communication with ADM service and for regular auto-upgrades. For more information, see Configure the ADC built-in agent to manage instances.

Upgrade and downgrade a NetScaler appliance

IMPORTANT:

File-based licensing system (also referred to as manually managed entitlements), traditionally used for activating various on-premises components, will be End of Life (EOL) on April 15, 2026. License Activation Service (LAS) is the next generation technology for product activations across the suite of Citrix products. LAS will be the only way to activate and license NetScaler instances after April 15, 2026, supporting NetScaler Flexed licenses (CPL/UHMC), legacy NetScaler Pooled licenses, and NetScaler Fixed term Bandwidth licenses. To remain supported, your NetScaler and NetScaler Console deployments must be on a LAS compatible version.

The minimum required NetScaler® versions that are LAS compatible are:

- NetScaler ADCs: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x
- NetScaler Console Service: Supported from early September 2025
- NetScaler Console on-prem: 14.1-51.x

  Note: LAS support for Console on-prem is from release 14.1-51.x onwards. However, file-based licensing is deprecated as of April 15 2026 from Console on-prem releases 14.1-51.x onwards and 13.1-60.x onwards. If you upgrade to Console on-prem release 14.1-51.x or release 13.1-60.x or later, you can continue using file-based licensing until 15th April 2026. However you must upgrade to Console on-prem release 14.1-51.x or later, and switch to LAS before 15th April 2026 because Console on-prem 13.1 does not support LAS.

All the other forms of legacy NetScaler licenses such as Pooled vCPU, CICO, perpetual will not be supported with LAS. NetScaler instances leveraging perpetual licenses without an active maintenance will become unlicensed upon upgrade to the above mentioned software versions.
LAS based licenses may not be available to customers where prohibited by law or regulations.
If you have questions or concerns, contact Customer Care. Citrix® may limit or suspend your Citrix Maintenance for non-compliance with these requirements without liability in addition to any other

© 1997–2026 Citrix Systems, Inc. All rights reserved.

remedies Citrix may have at law or equity. These requirements don’t apply where prohibited by law or regulation.
NetScaler 14.1 offers new and updated features with increased functionality. A comprehensive list of enhancements is listed in the release notes accompanying the release announcement. Read the release notes document before you upgrade your software.

This section provides information about **upgrading and downgrading a NetScaler appliance** (MPX and VPX) firmware **by using the NetScaler GUI or CLI**.

You can also **use NetScaler Console to upgrade a NetScaler appliance**. For more information, see:

- 10 ways NetScaler Console service supports easier NetScaler upgrades
- Use NetScaler Console service to upgrade NetScaler instances
- Use NetScaler Console software to upgrade NetScaler instances

For information about **upgrading a NetScaler SDX appliance**, see Single Bundle Upgrade.

Before you begin

Before you start the upgrade or downgrade process, make sure you check the following:

- Evaluate your organization's support agreement. Document appliance serial number, support agreement, and contact details for support from Citrix® technical support or the Citrix Authorized Partner.
- Time allocated for upgrading NetScaler appliances. Follow your organization's change control procedure. Allocate twice as much time to perform the upgrades. Allocate enough time to upgrade each of the NetScaler appliance.
- The NetScaler licensing system enforces Customer Success Services (CSS) membership license validation for NetScaler VPX appliances. Before you upgrade a NetScaler VPX appliance, ensure that the current CSS membership of the appliance is valid and has not expired.

  Ensure that the current CSS membership expiration date is equal or newer than the CSS eligibility date of the NetScaler product version to be upgraded.

  If the CSS membership expiration date is earlier than the CSS eligibility date, then the existing license does not work on the upgraded version of the NetScaler VPX appliance. This

© 1997–2026 Citrix Systems, Inc. All rights reserved.

functionality can prevent unauthorized usage of the licenses. You must renew the CSS membership before you can upgrade the NetScaler VPX appliance.

For a list of NetScaler VPX releases and their CSS eligibility dates, see NetScaler product Customer Success Services Eligibility Dates.

For more information about CSS, see Customer Success Services.

- We recommend upgrading to one major release at a time. For example, if the NetScaler appliance is on release 12.1, and you want to upgrade to release 14.1, first upgrade the appliance to release 13.1, and then to release 14.1.
- The licensing framework and types of licenses. A software edition upgrade might require new licenses, such as:
  - upgrading from the standard edition to the advanced edition, or
  - the standard edition to the Premium edition, or
  - the advanced edition to the Premium edition.

  Existing NetScaler licenses continue to work when you upgrade to version 14.1. For more information, see Licensing.
- Check the New and deprecated commands, parameters, and SNMP OIDs.
- Check the NetScaler MPX Hardware Compatibility Matrix and NetScaler SDX Software Compatibility Matrix.
- If the NetScaler Gateway logon page is customized, then make sure that the UI theme is set to default.
- If you are upgrading LOM, review the LOM Firmware Upgrade page.
- Download the NetScaler firmware from the NetScaler Downloads. For the detailed steps to download the NetScaler firmware, see the Download a NetScaler release package.
- Back up files. Perform a backup of the configuration file, customization file, certificates, monitor scripts, license files, and so on either manually or refer to the following documentation for back-up using NetScaler CLI or GUI - Backup and restore.
  - Refer to the following list for other common customized files for backup.
    - `/nsconfig/monitors/*.pl`
    - `/nsconfig/rc.netscaler`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Back up and delete the customization folder. The folder is usually in the path `/var/customizations`. An example of customization is a logon page with a logo. After you have copied the customizations folder, you have to delete it from the NetScaler appliance, before you upgrade the appliance. Upgrading with customization in place might cause some issues.

IMPORTANT:

We recommend that you review the backup procedures first and have an action plan in case the update does not complete on NetScaler.

- Verify that there is adequate space in the `/var` and `/flash` directory for the NetScaler appliance before performing an upgrade. The `/var` directory requires 7 GB of free space (1 GB for the upgrade bundle, 2 GB for extraction, and 4 GB for the upgrade process) The `/flash` directory requires anywhere between 140 MB to 160 MB space to copy the new kernel. Therefore, ensure that there is at least 250 MB free space available. For more information on clearing out the disk space in `/var`, see How to free space on /var directory for logging issues with a NetScaler appliance. For more information on clearing out the disk spaces in `/flash`, see `<https://support.citrix.com/article/CTX133587>`.
- Verify that there are no invalid configurations before performing an upgrade using the preconfiguration check tool. This tool is also run by default during the upgrade process and as part of the `installns` script. To avoid upgrade failures due to invalid configuration, it is recommended to run the preconfiguration check tool before upgrade. For more information, see Preconfiguration check tool.

  If there are configurations related to classic policies, see Upgrade considerations for configurations with classic policies and Classic Policy Deprecation FAQs.

  If there are any invalid configurations, use the `nspepi` tool for converting the invalid configurations to valid configurations. For information about the `nspepi` tool, see Converting policy expressions using NSPEPI tool.

NOTE:

If you select option `Y` in the `installns` script for upgrading the build, the preconfiguration check is not performed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Validate the integrity of the NetScaler appliance. If you have a NetScaler hardware appliance, Citrix highly recommends running `fsck` for running a disk check and validating the integrity of the NetScaler hard drive. In the event of an error, reset the hard disk drive and repeating the disk check command. If the error message reappears, contact NetScaler support to further investigate the issue.
    - Validate the disk integrity of the hard drive using a `fsck` command. For more information, see CTX122845.
    - Validate the integrity of NetScaler using the diagnostic bundle files and upload the logs to Citrix Insight Service for analysis.
- Check the NetScaler VPX Support matrix and usage guidelines.
- Check the FAQ section.
- Verify the upgrading procedures with a test environment.
- Before upgrading NetScaler (ADC or SVM), the system checks for a valid local license. This upgrade check applies to the following legacy file-based NetScaler local license types:
    - Legacy file-based NetScaler perpetual licenses
    - Legacy file-based NetScaler Fixed Capacity Subscription licenses

  The upgrade proceeds if one of the following conditions is met:
    - NetScaler (ADC, SVM) has a legacy file-based NetScaler Perpetual license, and the Subscription Advantage (SA) date has not expired, which means the SA date has not crossed the NetScaler build date to which the customer is attempting to upgrade.
    - NetScaler (ADC, SVM) has a legacy file-based Fixed Capacity Subscription license, and the contract license expiry date is not yet reached.
    - A valid and active LAS-based Fixed Capacity Subscription license activation blob is applied.

  If none of these checks are met, the upgrade is blocked and aborted. If the upgrade is blocked, we recommend that the customer apply a valid license and then retry the upgrade.

Pre-upgrade validation checks for NetScaler

NOTE:

This feature is available in NetScaler release 14.1 build 66.x and later.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Pre-upgrade validation checks are built into the upgrade workflow to ensure safer system upgrades and confirm that the system is ready for the upgradation process. The following are the prechecks added to the upgrade workflow.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
EOL of file-based licensing	Checks whether the license mechanism in use from April 15, 2026 onwards is file-based licensing or LAS-based licensing. For more information, see EOL of file-based licensing.	• SUCCESS: Using LAS-based licensing • FAILED: Using file-based licensing	How to override	Older licensing mechanism (that is, file-based licensing) reaches end-of-life from April 15, 2026 and LAS-based licensing is required.	
License expiry check	Verifies both contract and runtime license validity.	• SUCCESS: License active • FAILED: License expired	Not applicable	Expired licenses might block data path or feature availability.	
License server connectivity (Pooled licensing)	Ensures that NetScaler can reach the license server. Required for	• SUCCESS: Connect	• DEFAULT: Continu	Connectivity issues might result in temporary degraded licensing	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
	pooled licensing environments.	ivity intact • WARNING: Unable to connect	e upgrade • OVERRIDE: use -E flag	behavior, but the upgrade is not blocked.	
License server compatibility (Pooled licensing)	Validates that the license server version is compatible with the upgrade.	• SUCCESS: Compatible • FAILED: Not compatible	Not applicable	Run only if the connectivity check passes. Incompatible license servers (NetScaler Console) must be upgraded first.	
Non-existent symbol used in nsapi_mgr calls in startup files	Ensures that startup scripts reference valid symbols to avoid boot time failures.	• SUCCESS: all symbols found • WARNING: symbols not found	• DEFAULT: Cancel • OVERRIDE: use -p flag	Missing symbols might break data path initialization or custom workflows.	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
New build compatibility with the NetScaler platform	Checks whether the hardware or the virtual platform supports the new build.	• SUCCESS: Compatible • FAILED: Not compatible	Not applicable	Ensures major hardware and software compatibility.	
Custom HTTPD and SSHD configuration files	Checks for symlink based overrides of HTTPD or SSHD configurations.	• SUCCESS: No symlinks • ADVISORY: Symlink exists	Not applicable	Admins must verify custom configurations for post upgrade compatibility. For more information, see Upgrade considerations.	
VPX resource requirements	Validates minimum memory requirements for VPX instances.	• SUCCESS: Memory OK • FAILED: Minimum memory	Not applicable	Insufficient memory might cause upgrade failures or unstable operations.	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
		check failed			
Disk space on `/flash` and `/var`	Validates the minimum disk space for upgrade package unpacking and operations.	• SUCCESS: Sufficient space • FAILED: Insufficient space	Not applicable	Low disk space might corrupt the upgrade or prevent the installation.	
Conditions for upgrade to 14.1-66.x and later releases (direct upgrade from version 13.0 to 14.1 is blocked)	Validates that the current firmware is eligible for upgrade.	• SUCCESS: Allowed • FAILED: Not allowed	Not applicable	Step upgrade enforced. For example, a direct upgrade from 13.0 to 14.1-66.x is blocked.	
Platform check: FIPS to NON-FIPS	Checks if platform restrictions block upgrade to a FIPS build.	• SUCCESS: Allowed • FAILED: Not allowed	Not applicable	FIPS compliance prevents installing FIPS builds on non-FIPS platforms.	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
Check for unsaved configuration	Detects unsaved running configuration.	• SUCCESS: Config saved • WARNING: Config not saved	• DEFAULT: Abort • OVERRIDE: use --ignore_unsaved_config flag	Unsaved configuration might result in a loss of configuration after rebooting.	
HA sync check	Checks if the configuration is in sync between the HA nodes.	• SUCCESS: In sync • WARNING: Not in sync	• DEFAULT: Abort • OVERRIDE: use --ignore_unsynced_config flag	Required to avoid split-brain or post-upgrade failover issues.	
Perpetual license subscription advantage (SA) expiry (Flexera)	Checks if SA is valid for perpetual licenses.	• SUCCESS: SA valid • FAILED: SA expired	Not applicable	SA expiry blocks the upgrade due to license entitlement enforcement.	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

PRE-CHECK	DESCRIPTION	STATUS	DEFAULT BEHAVIOR AND OVERRIDE	ADDITIONAL COMMENTS	
SSL certificate file integrity	Verifies SSL certificate file integrity using digest checks.	• SUCCESS: All good • WARNING: Verification failed	• DEFAULT: Abort • OVERRIDE: use –C flag	Corrupt or missing certificates might disable SSL features.	

EOL of file-based licensing

NOTE:

These checks come into effect from April 15, 2026.

File-based licensing will be EOL from April 15, 2026. All NetScaler (ADC, SVM) instances must be upgraded to LAS-compliant versions and transitioned to use LAS-based licensing before this date.

The minimum required NetScaler versions that are LAS compatible are:

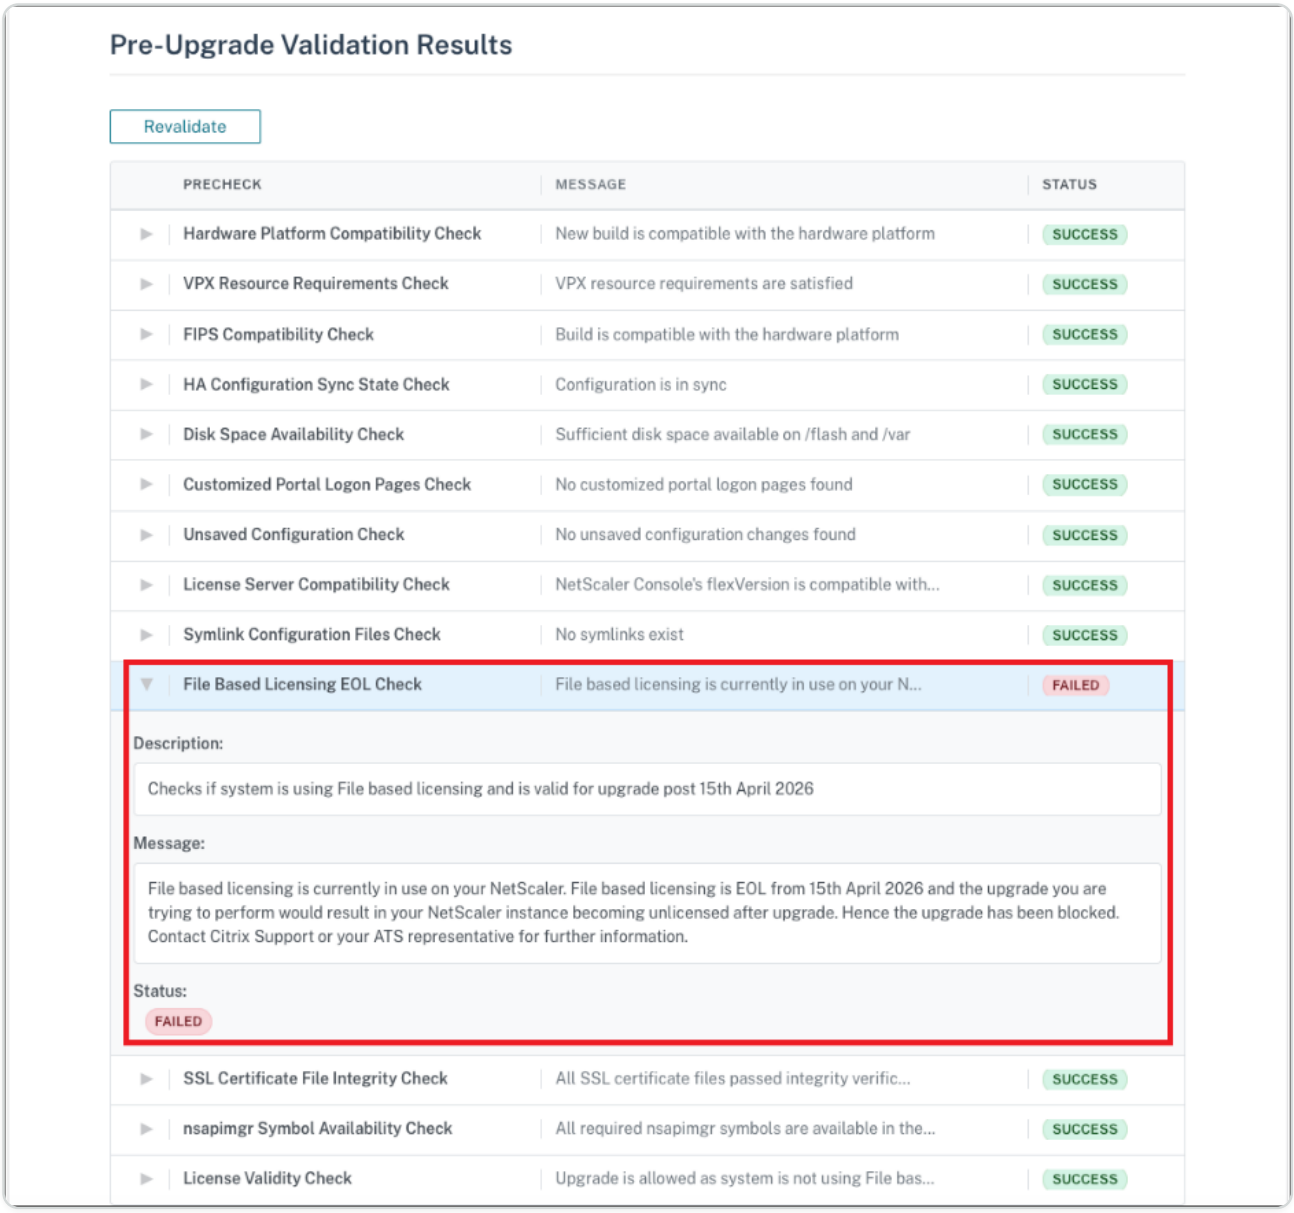
- NetScaler ADCs: 14.1-51.x, 13.1-60.x, 13.1-37.246 (FIPS)
- NetScaler SVM: 14.1-51.x, 13.1-60.x

After April 15, 2026, in NetScaler ADC and SVM release 14.1-66.x and later, an upgrade related check will be triggered before NetScaler upgrade. This check validates if your NetScaler (ADC, SVM) is still using file-based licensing, and if true, the upgrade would be blocked with an error "NetScaler Upgrade Blocked: File based licensing in use". This precaution avoids your NetScaler instances from proceeding with the upgrade and becoming unlicensed after April 15, 2026.

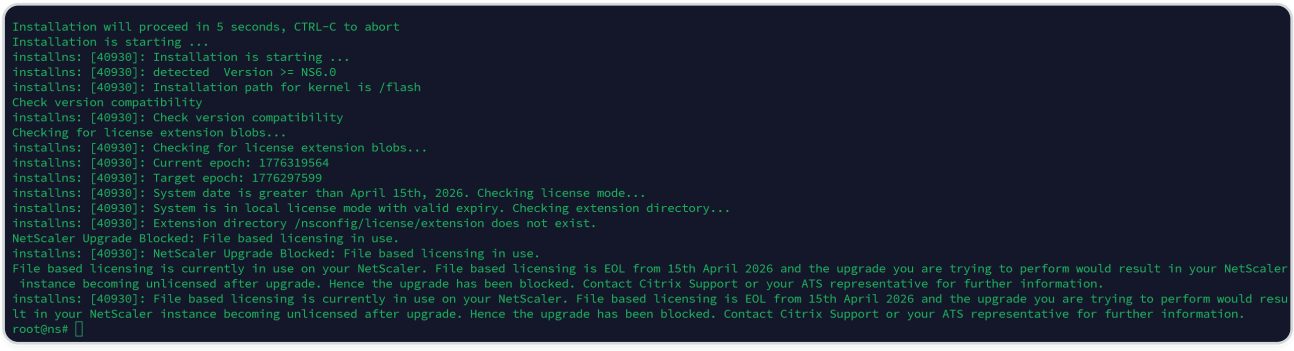
Contact Citrix Support or your ATS representative to understand how you can unblock the upgrade and the risks involved with it.

The following screenshot shows the message in the NetScaler GUI.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



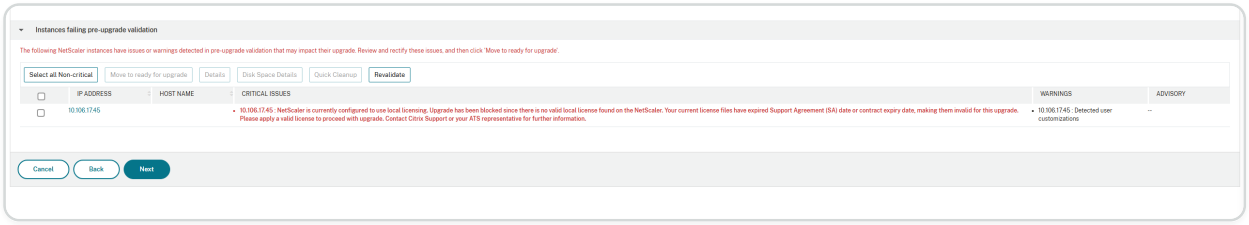
The following screenshot shows the message in the NetScaler CLI.



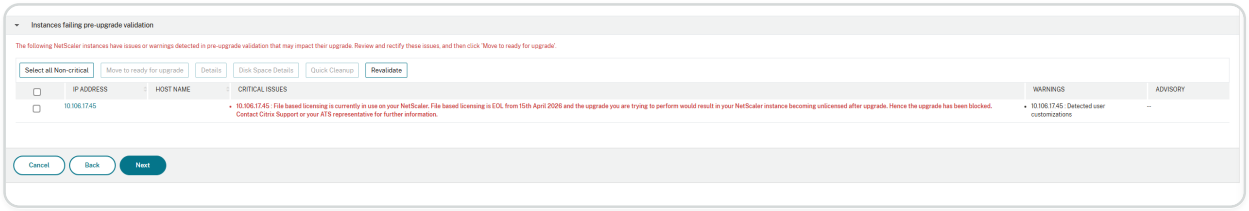
The following screenshots show the messages in NetScaler Console.

- When file-based licensing is in use, and the contract date has expired.

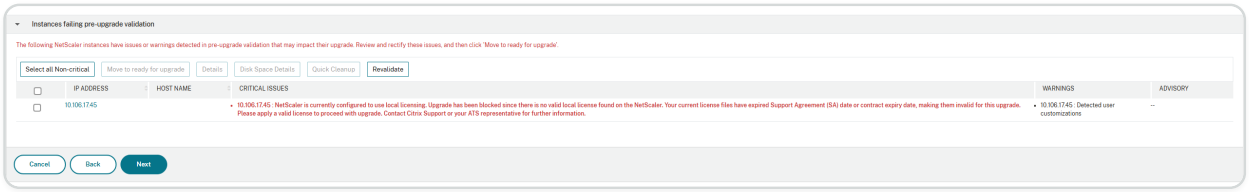
© 1997–2026 Citrix Systems, Inc. All rights reserved.



- When file-based licensing is in use, which has reached EOL on April 15, 2026.



- When file-based licensing is in use, and the SA date has expired.



The following message appears in the NetScaler API response.

File based licensing is currently in use on your NetScaler. File based licensing is EOL from 15th April 2026 and the upgrade you are trying to perform would result in your NetScaler instance becoming unlicensed after the upgrade. Hence the upgrade has been blocked. Contact Citrix Support or your ATS representative for further information.

Resolve file-based licensing upgrade blocks

Effective April 15, 2026, all ADC and SVM instances must upgrade to LAS-compliant versions. You must migrate to LAS-based licensing before this date. If your upgrade is blocked with a **File-based licensing in use** error, resolve this issue either by procuring a new LAS-based license or temporarily overriding the licensing check.

Procure and apply a LAS-based license (recommended)

1. Procure a LAS-based license. Ensure that this license is sufficient for your deployment. Contact your ATS or Citrix Customer Support to obtain the license.

IMPORTANT:

Take a system backup before you attempt the upgrade.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. After the LAS licensing is in place, continue with the upgrade through the standard upgrade workflow.

Override or bypass the licensing check during upgrade

NOTE:

This option is available, but we do not recommend it.

This option allows you to bypass the file-based licensing validation and continue with the upgrade. Use this approach only as a last resort, typically for emergency or short-term recovery scenarios where an immediate upgrade is required and where migration to LAS-based licensing cannot be completed on time.

IMPORTANT:

This method might result in an unlicensed state after the upgrade and cause a loss of configuration.

Before attempting the upgrade, ensure that you take a system backup.

To override or bypass the licensing by using the CLI

1. At the command prompt, type `shell`.
2. Switch to the directory where the install package is untarred (for example, `cd /var/nsinstall/`).
3. Run the following command. `./installns --skip_lic_exp_chk`

To override or bypass the licensing by using the Automation or GUI (APIs or NetScaler GUI or NetScaler Console or any automation tool)

1. At the command prompt, type `shell`.
2. Create an empty file in /var/tmp.

   `touch /var/tmp/skip_las_checks`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Proceed with the normal upgrade workflow using the API or NetScaler GUI or NetScaler Console

To override or bypass the licensing for an SDX upgrade

1. Log in to the SVM and run the `shell` command.
2. Create a file named skip_las_prechecks in the `/mps` directory

   `touch /mps/skip_las_prechecks`
3. Proceed with the single bundle upgrade.

Upgrade considerations for configurations with classic policies

Classic policies are deprecated from NetScaler release 12.0 build 56.20. Starting with release 13.1, classic policy support is removed from some of the features. To know the complete list of features or commands that aren't supported from release 13.1 release, see **Table 2** in Notice of Status Change Announcement for NetScaler Classic Policy Based Features and Functionalities.

As a prerequisite for upgrading to release 13.1 or later, we recommend you to convert the classic policies to advanced policies for the features that are supported by the NSPEPI tool. To know the features that are supported by the NSPEPI tool, see Commands or features handled by the nspepi conversion tool. If you do not convert to advanced policies before the upgrade, then the upgrade fails due to invalid configuration.

IMPORTANT:

Before you upgrade to release 13.1 or later, we recommend you to run the preconfiguration check tool. This tool ensures that your configuration does not contain commands related to the deprecated or removed features. If there are any commands related to the deprecated or removed features, the tool throws an error and the configuration might be lost. We recommend you to download the latest version of the preconfiguration check tool from the public GitHub link - `<https://github.com/citrix/ADC-scripts/tree/master/nspepi>`.

For more information, see the Preconfiguration check tool before upgrade.
If there are any errors as part of the preconfiguration check, we recommend you to use the `nspepi` tool to convert the invalid configurations to valid configurations. Download the latest version of the `nspepi` tool from the public GitHub link - `<https://github.com/citrix/ADC-`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`scripts/tree/master/nspepi>`. For more information on converting policy expressions using the `nspepi` tool, see Converting policy expressions using NSPEPI tool.

If you miss converting the classic policies before the upgrade, you can choose to convert to advanced policies during the upgrade. As part of the upgrade, you can choose one of the options described in the following table while running the `./installns` command.

OPTION	DESCRIPTION
No option	If there are any errors as part of the preconfiguration check, the installation stops. You must convert classic policies to advanced policies to proceed with the upgrade process.
-M	NSPEPI tool is run as part of the installation and converts classic policies to advanced policies.
-Y	This option isn't recommended. In this option, the preconfiguration check is skipped and therefore any valid configuration might get lost.

To convert classic policies to advanced policies during the upgrade, select the `-M` option. The `-M` option triggers the NSPEPI tool and updates the existing `ns.conf` file with the modified configuration. The old configuration is present at `/nsconfig/ns.conf_old` for future reference.

```
./installns -M
```

If you find any error during the advanced policy conversion, contact NetScaler support.

The `nspepi` tool does not handle the conversion for a few commands or features. See Commands or features not handled by the nspepi conversion tool for the complete list.

NOTE:

If you have classic policies and want to convert them to advanced policies during the upgrade, then you can use the regular upgrade procedure (HA or Cluster or Standalone setup) but use the "-M" option with `installns` command.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you want to convert the configuration before the upgrade, then perform the following steps for each configuration:

1. Run the `nspepi` tool on Citrix ADC release 12.1 or 13.0 to convert the `ns.conf` file. The NSPEPI tool generates two files with prefixes `new_` and `warn_`. The file with the `new_` prefix contains the converted configuration and the file with the `warn_` prefix contains the warnings and errors.
2. Check the file with the `warn_` prefix and fix errors (if any).
3. Test the converted configuration. Apply the converted configuration using one of the following options:

    a. Run the `clear config -f basic` command and then source the converted configuration by running the `source /nsconfig/new_ns.conf` command.

    b. Remove the classic commands manually (by unbinding and removing policies) and then source the converted configuration by running the `source /nsconfig/new_ns.conf` command.

    NOTE:

    You might see "Resource already exists" errors for the configurations that aren't cleared using the `clear config -f basic` command. You can ignore these errors.

4. Save the configuration.

After successfully converting invalid configurations to valid configurations, verify if there are any other prerequisites and then proceed to upgrade. For more information, see Upgrade and downgrade a NetScaler appliance.

Upgrade considerations for customized configuration files in the /etc directory

Before you upgrade a NetScaler, review any customized configuration files, especially in the `/etc` directory. Unreviewed customizations can block release updates or cause post-upgrade issues. This document explains which files can be customized and how to manage them safely during upgrade.

The following configuration files are supported to be modified in the `/etc` directory:

- `crontab`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `dhclient.conf` (In NetScaler VPX on Nutanix, this file is located in `/etc/dhcp/`.)
- `gettytab` (Not supported on NetScaler VPX on Nutanix.)
- `host.conf` (In NetScaler VPX on Nutanix, use `nsswitch.conf` instead.)
- `hosts`
- `httpd.conf` (In NetScaler VPX on Nutanix, this file is `/etc/blx/nshttpd.conf`.)
- `inetd.conf` (Not supported on NetScaler VPX on Nutanix.)
- `issue` (In NetScaler VPX on Nutanix, this file is `/etc/blx/nsissue.net`.)
- `ldap.conf`
- `localtime`
- `monitrc`
- `motd`
- `newsyslog.conf` (In NetScaler VPX on Nutanix, use `/etc/logrotate.d/blx-syslog`.)
- `nsssl.conf`
- `ntp.conf`
- `ntpd_ctl` (Not supported on NetScaler VPX on Nutanix.)
- `profile`
- `rc.conf` (Not supported on NetScaler VPX on Nutanix.)
- `resolv.conf`
- `ssh_config`
- `sshd_config` (In NetScaler VPX on Nutanix, this file is `/etc/blx/nssshd_config`.)
- `syslog.conf` (In NetScaler VPX on Nutanix, use `rsyslog.conf` instead.)
- `ttys` (Not supported on NetScaler VPX on Nutanix.)

NOTE:

New files might be added to the above list depending on the NetScaler build running on the appliance. You can display an updated list of files by running the following shell command in the NetScaler command line interface:

```
grep NSETC= /etc/rc
```

To display the list of files on NetScaler VPX on Nutanix, run the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`sed -n '/NSETC="/,/"/p' /sbin/vpx-startup.sh | tr -d '"' | tr -d '\\' | xargs -n1`

If you have modified any of the configuration files in the `/etc` directory and copied it to the `/nsconfig` directory, to maintain persistency, the NetScaler appliance creates a symlink in `/etc` pointing to the file in `/nsconfig`.

For example: `/etc/httpd.conf -> /nsconfig/httpd.conf`

A release package might contain its own version of the configuration files in the `/etc` directory. These configuration files include important updates that are required for the NetScaler appliance to properly function. Upgrading a NetScaler appliance to a release replaces the configuration files in the `/etc` directory with the configuration files containing the release updates.

Consider an example of a customized configuration file, `example.conf`, which is present in the `/etc` directory. The `example.conf` file is copied to the `/nsconfig` directory to maintain persistency. The NetScaler appliance creates a symlink in `/etc` pointing to the file in `/nsconfig`: `/etc/example.conf -> /nsconfig/example.conf`

Also, a release package includes its own version of `example.conf`, which contains important updates. The following behavior is observed when you upgrade the NetScaler appliance to the release:

Because the symlink `/etc/example.conf` is already present, the NetScaler appliance does not place the release package copy of the `example.conf` in the `/etc` directory during the upgrade process.

As the release package copy of `example.conf` contains important updates, the absence of it in the `/etc` directory can cause the NetScaler appliance to fail or to not properly function.

Steps to preserve upgrade changes and customization

To ensure that both release updates and your customizations are not lost, perform the following steps:

- Pre-upgrade steps:
  - Back up customized file before upgrade
  - Remove persistency of customized file before upgrade
- Post-upgrade steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Apply customizations to upgraded file and add persistency after upgrade

IMPORTANT:

Do NOT directly replace your customized file in the `/etc` folder. Directly replacing a `/etc` file with the back-up customized file removes any release updates added to the file during the upgrade process.

Back up customized file before upgrade

Take a backup of the customized files present in the `/nsconfig` directory before upgrading the appliance.

Create a `/var/nsconfig_backup` directory and move the customized files to this directory. That is, move any files that you modified in the `/etc` directory and copied to `/nsconfig` by running the following command at the shell prompt:

```
mv /nsconfig/<filename> /var/nsconfig_backup/
```

Example:

```
mv /nsconfig/httpd.conf /var/nsconfig_backup/
```

Remove persistency of customized file before upgrade

Delete the `/etc` symlinks that are pointing to the `/nsconfig` files before upgrading the appliance.

1. Check the existing symlinks in the `/etc` directory by running the following command at the shell prompt:

   ```
   ls -la /etc
   ```

2. Delete a `/etc` symlink pointing to a `/nsconfig` file by running the following command at the shell prompt:

   ```
   unlink /etc/<filename>
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example:

```
unlink /etc/httpd.conf
```

3. Verify that the symlink is removed by running the following command at the shell prompt:

```
cat /etc/<filename>
```

Example:

```
cat /etc/httpd.conf
```

This command does not display any content if the symlink is removed.

Apply customizations to upgraded file and add persistency after upgrade

If you have taken a backup of any modified `/nsconfig` config file to the `/var/nsconfig_backup`, do the following after upgrading the appliance:

1. Compare the file present in the `/var/nsconfig_backup` and the `/etc` directories. Manually add the appropriate changes to the `/etc` file already containing the release updates.

IMPORTANT:

Directly replacing the `/etc` file with the `/var/nsconfig_backup` file removes any release updates added to the file during the upgrade process. This removal of updates can cause the related NetScaler functionalities to fail or to not work properly.

2. To maintain persistency, copy the updated file present in the `/etc` directory to the `/nsconfig` directory by running the following command at the shell prompt:

```
cp /etc/<filename> /nsconfig/
```

Example:

```
cp /etc/httpd.conf /nsconfig/
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Repeat the above two steps for each customized file present in the `/var/nsconfig_backup` directory.
4. Restart the appliance to put the changes into effect.

Upgrade considerations - SNMP configuration

The timeout parameter for an SNMP alarm is an internal option that has no impact on the alarm configuration.

Timeout parameter might appear in the SNMP alarm configurations in the running configuration (sh running) and the saved configuration (ns.conf) even if you have not made any changes to these SNMP alarm configurations.

On upgrading to a release build with the fix for the timeout setting issue, the SNMP configurations are erroneously reset to default values.

The following SNMP alarms (if configured) are impacted during an upgrade:

- APPFW-BUFFER-OVERFLOW
- APPFW-COOKIE
- APPFW-CSRF-TAG
- APPFW-DENY-URL
- APPFW-FIELD-CONSISTENCY
- APPFW-FIELD-FORMAT
- APPFW-POLICY-HIT
- APPFW-REFERER-HEADER
- APPFW-SAFE-COMMERCE
- APPFW-SAFE-OBJECT
- APPFW-SQL
- APPFW-START-URL
- APPFW-VIOLATIONS-TYPE
- APPFW-XML-ATTACHMENT
- APPFW-XML-DOS
- APPFW-XML-SCHEMA-COMPILE
- APPFW-XML-SOAP-FAULT

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- APPFW-XML-SQL
- APPFW-XML-VALIDATION
- APPFW-XML-WSI
- APPFW-XML-XSS
- APPFW-XSS
- CLUSTER-BACKPLANE-HB-MISSING
- CLUSTER-NODE-HEALTH
- CLUSTER-NODE-QUORUM
- CLUSTER-VERSION-MISMATCH
- COMPACT-FLASH-ERRORS
- CONFIG-CHANGE
- CONFIG-SAVE
- HA-BAD-SECONDARY-STATE
- HA-NO-HEARTBEATS
- HA-SYNC-FAILURE
- HA-VERSION-MISMATCH
- HARD-DISK-DRIVE-ERRORS
- HA-STATE-CHANGE
- HA-STICKY-PRIMARY
- PORT-ALLOC-FAILED
- SYNFLOOD

These SNMP alarms configurations are impacted when you upgrade the NetScaler to the following release builds:

- Release 11.1 build 61.2 or later
- Release 12.0 build 61.0 or later
- Release 12.1 build 30.1 or later
- Release 13.0 build 51.4 or later

Example

Let's consider an example of CLUSTER-NODE-HEALTH SNMP alarm.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
CLUSTER-NODE-HEALTH SNMP alarm is set up by using the NetScaler command
line:

> set snmp alarm CLUSTER-NODE-HEALTH -time 111 -state DISABLED -severity
Major

> save config
```

This SNMP alarm configuration appears in the saved configuration file (`ns.conf`) as:

```
set snmp alarm CLUSTER-NODE-HEALTH -time 111 -state DISABLED -severity
Major -timeout 86400
```

During an upgrade to any of the release builds mentioned above, the following error appears in ns.log file:

```
May 23 09:14:46 <local0.err> ns nsconfigd: __init_config_filter(): (null)
line 0: No such argument [-timeout]>> set snmp alarm CLUSTER-NODE-HEALTH
-time 111 -state DISABLED -severity Major -timeout 86400.
```

After the upgrade, the SNMP alarm configurations are reset to the default values.

Workaround

Use one of the following workarounds:

- Before the upgrade, remove the timeout setting from the SNMP configurations in the saved configuration file (ns.conf).
- After the upgrade, reconfigure the SNMP alarms without the timeout parameter.

Download a NetScaler release package

Complete the following steps to download a NetScaler release package:

1. Open NetScaler Downloads page in a Web browser.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the NetScaler Downloads page, expand the **NetScaler release** that you want to update to.
3. Expand one of the appropriate categories, and click the NetScaler build link. For example, for downloading a version of NetScaler firmware, expand **Firmware**, and click the NetScaler build that you want to download.
4. On the selected NetScaler build page, expand the **Build** section, click **Download File** to download the NetScaler build package.

NOTE:

The checksum is provided to ensure that you match the downloaded build package with the actual package which is hosted on the website. Checksum is an important check to ensure that you have the correct bits.

Upgrade a NetScaler standalone appliance

Before upgrading the system software, make sure that you read the Before you begin section and complete the prerequisites such as backing up the necessary files and downloading the NetScaler® firmware.

Upgrade a NetScaler standalone appliance by using the GUI

Follow these steps to upgrade a standalone NetScaler to release 14.1 by using the GUI.

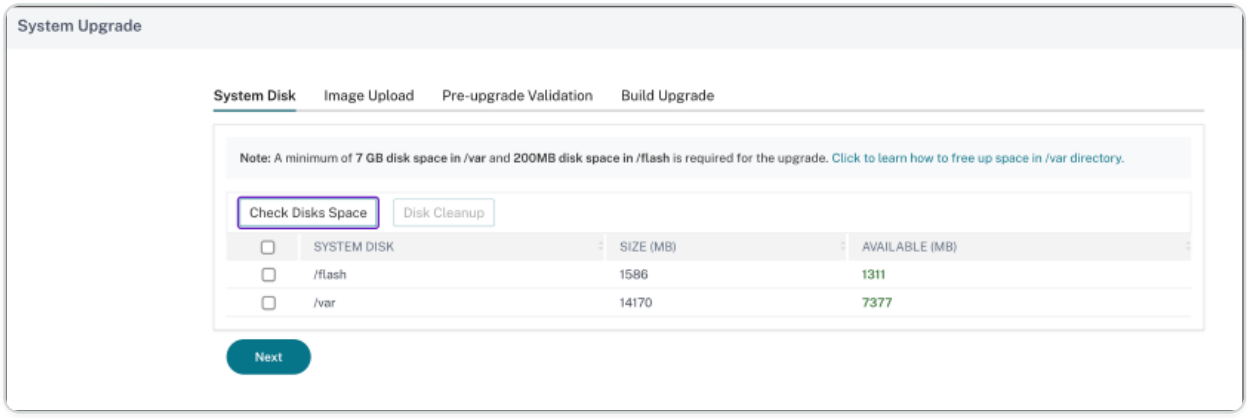
1. In a web browser, type the IP address of the NetScaler, for example `http://10.102.29.50`.
2. In User Name and Password, type the administrator credentials (nsroot/nsroot) and then click **Log On**.
3. Navigate to **System** and click **System Upgrade**.
4. Click **System Disk** to check whether enough space is available on the device.

   NOTE:

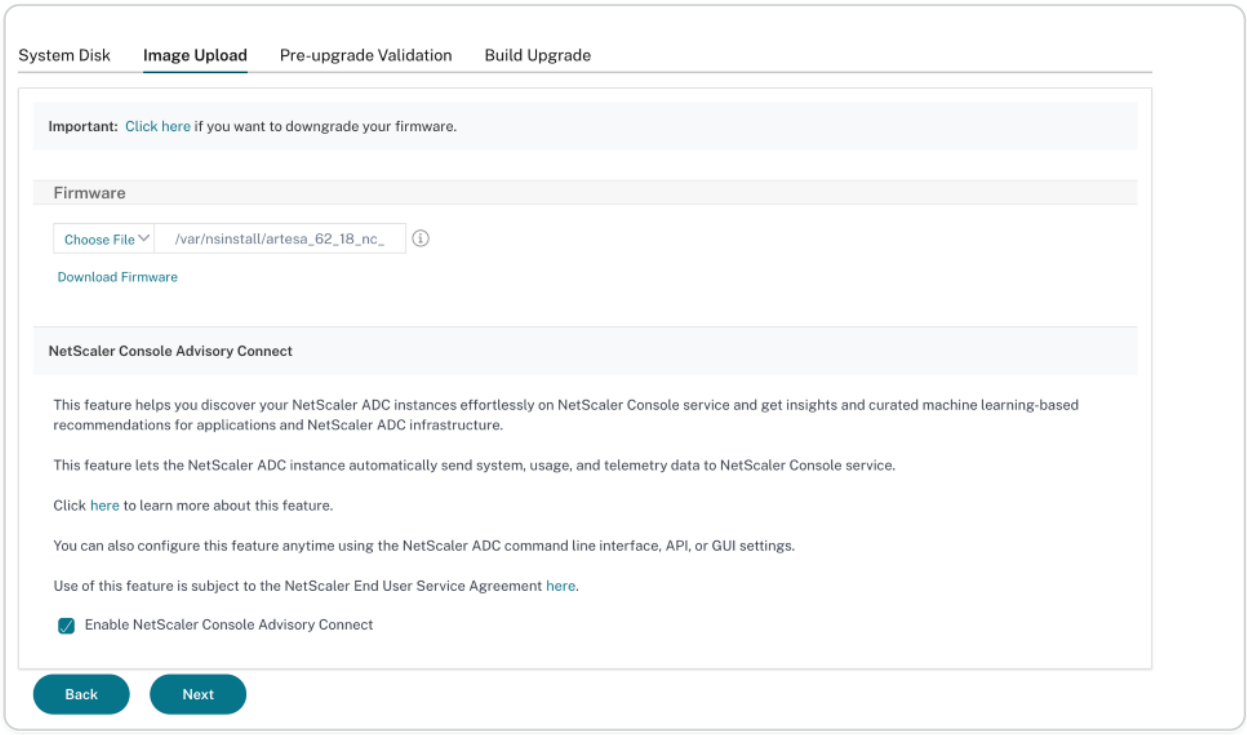
   A minimum of 7 GB disk space in `/var` and 200 MB disk space in `/flash` is required for the upgrade.

5. If enough space is not available, click **Disk Cleanup** and choose the directories to clear enough space.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

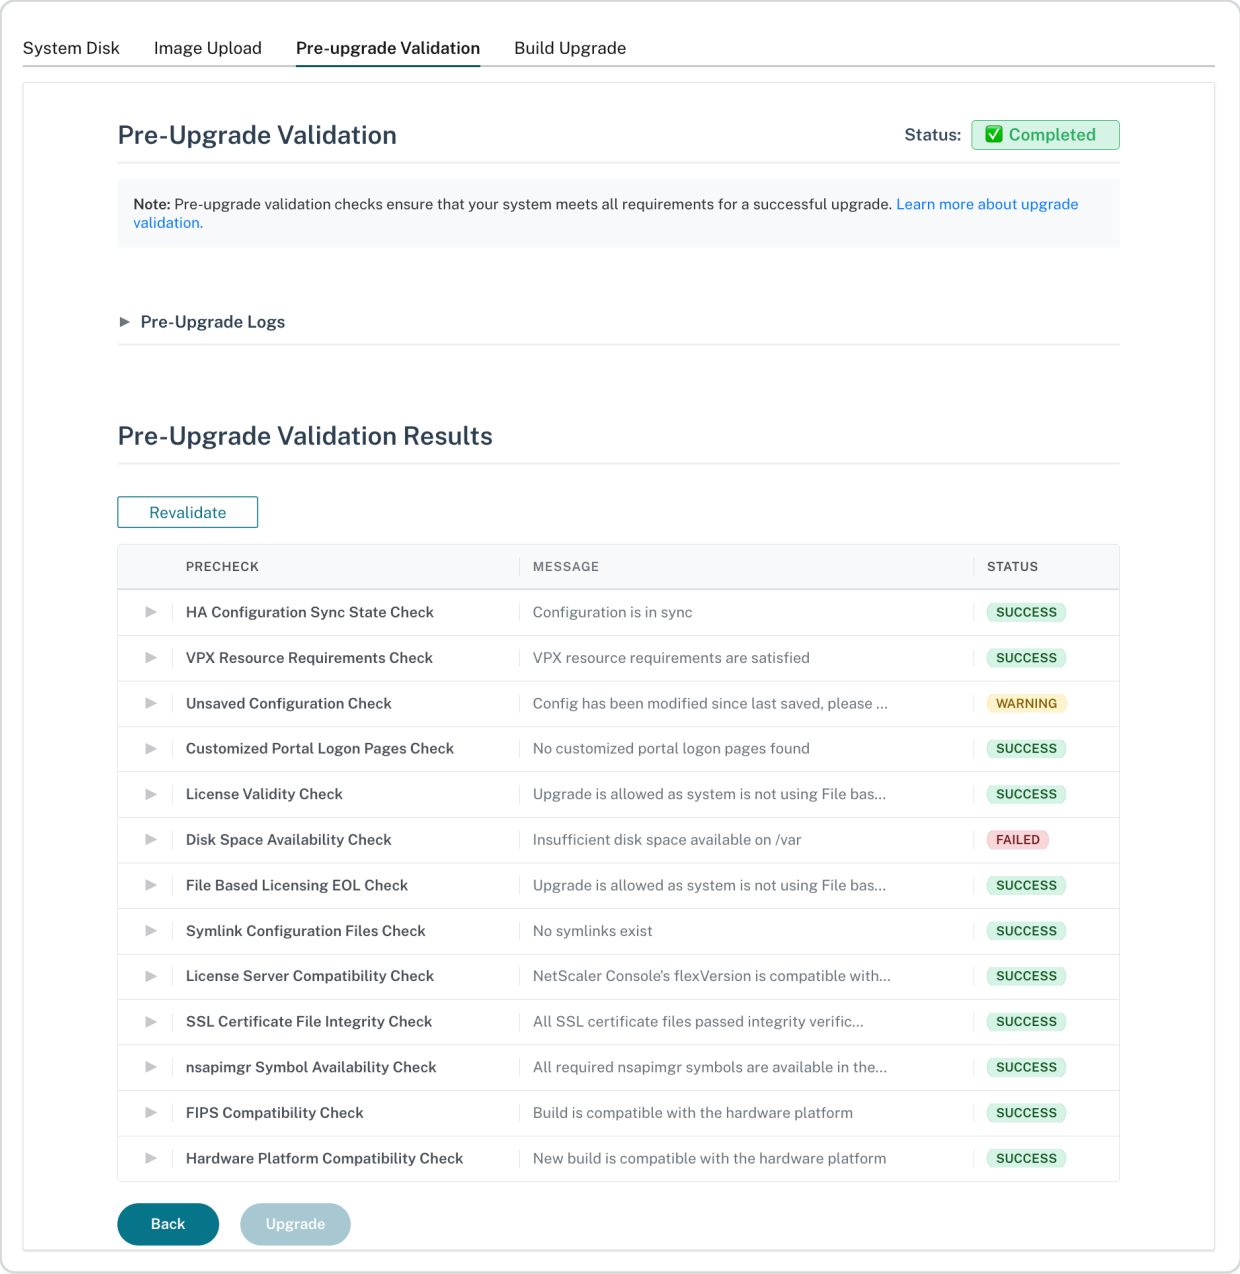


6. Click **Next** to open the **Image Upload** tab, from the **Choose File** menu, select the appropriate option: **Local** or **Appliance**. To use the **Appliance** option, you must upload the firmware to the NetScaler first. You can use any file transfer method such as WinSCP to upload the NetScaler firmware to the appliance.



7. Click **Next** to open the **Pre-upgrade Validation** tab. The device performs pre-upgrade validation checks.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



For any Failed or Warning check, click the row to view the error, then use the action button at the end of the status row to take corrective action.

NOTE:

For a Warning check, fix the warning and click **Revalidate** before you continue. If you are sure it does not affect the system, click **Ignore Warning & Upgrade**. This can cause configuration loss, such as unsaved changes.

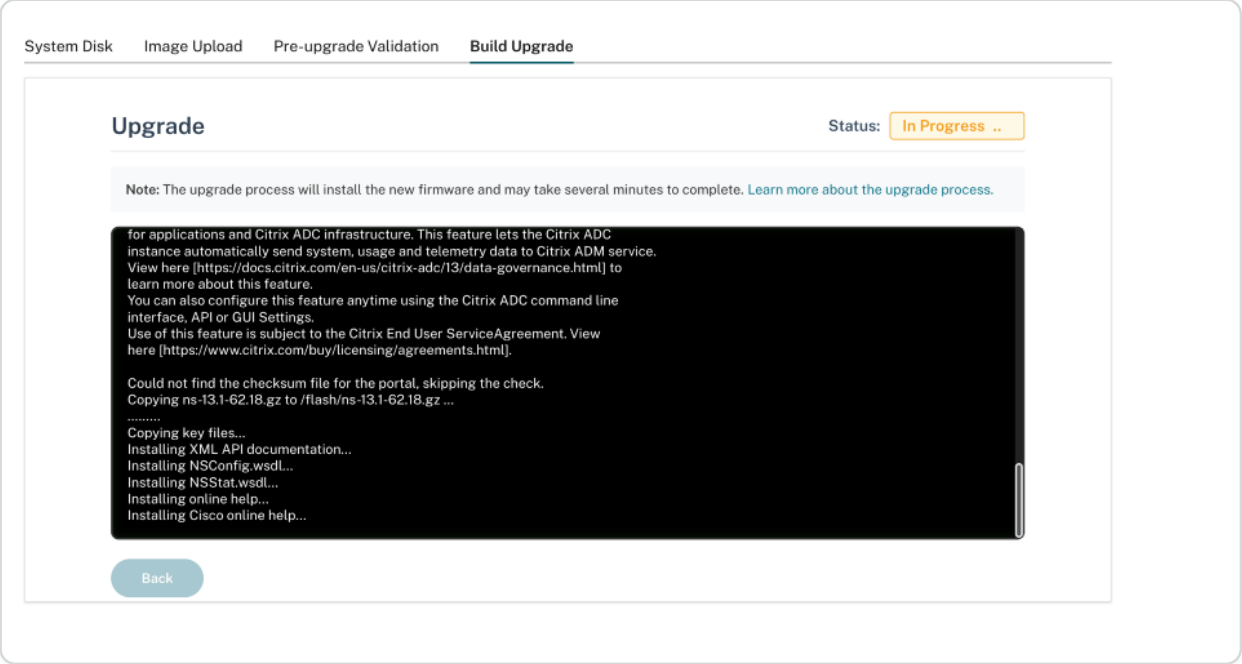
8. Click **Revalidate** (at the top of the validation tasks) to ensure that no checks fail. For more details about the pre-upgrade check performed, see Pre-upgrade validation checks for NetScaler.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

9. Click **Upgrade** to proceed with the system upgrade.

   NOTE:

   The system reboots after a successful upgrade.



10. After the upgrade, close all browser instances and clear your computer's cache before accessing the appliance.

Upgrade a NetScaler standalone appliance by using the CLI

Follow these steps to upgrade a standalone NetScaler to release 14.1 by using the CLI:

In the following procedure, `<release>` and `<releasenumber>` represent the release version you are upgrading to, and `<targetbuildnumber>` represents the build number that you are upgrading to. The procedure includes optional steps to avoid losing any updates that are pushed to the /etc directory during the upgrade.

1. Use an SSH client, such as PuTTy, to open an SSH connection to the appliance.
2. Log on to the appliance by using the administrator credentials. Save the running configuration. At the prompt, type:

   ```
   save config
   ```

3. Switch to the shell prompt by running the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

`shell`

4. Create a copy of the ns.conf file. At the shell prompt, type:

   - `cd /nsconfig`
   - `cp ns.conf ns.conf.NS<currentreleasenumber><currentbuildnumber>`

   You must take a backup of the configuration file to another computer.

5. **IMPORTANT:**

   It is important that both the upgrade changes and your customizations are applied to an upgraded NetScaler appliance. So, if you have customized configuration files in the `/etc` directory, perform the **pre-upgrade steps** in Upgrade considerations for customized configuration files

6. Create a location for the installation package. At the shell prompt type:

   - `cd /var/nsinstall`
   - `cd <releasenumber>`

     NOTE:

     If the desired release number directory is not present, create one using the following command:

     `mkdir <releasenumber>`

     Example:

     `mkdir 14.1`

   - `mkdir build_<targetbuildnumber>`
   - `cd build_<targetbuildnumber>`

7. Copy the already downloaded NetScaler firmware to the build directory that you have created in the preceding step, by using any file transferring method such as WinSCP. See the Before You Begin section for more information about downloading the NetScaler firmware.
8. Extract the contents of the installation package. Example:

   `tar -xvzf build-14.1-60.58_nc_64.tgz`

9. Run the following script to perform the pre-upgrade checks in NetScaler.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
./installns --pre_check
```

NOTE:

For more information, see Pre-upgrade validation checks.

10. Run the `installns` script to install the new version of the system software.

    ```
    ./installns
    ```

    NOTE:

    During CLI upgrade, you might see the following prompt:

    ```
    Do you wish to delete old signature files and kernel images?
    ```

    In most cases, select **No** to retain older kernel images and corresponding signature files. Select **Yes** only if `/flash` has insufficient free space and cleanup is required to continue the upgrade.

11. When prompted, restart the NetScaler.

12. **IMPORTANT:**

    It is important that both the upgrade changes and your customizations are applied to an upgraded NetScaler appliance. So, if you have customized configuration files in the `/etc` directory, perform the **post-upgrade steps** in Upgrade considerations for customized configuration files

See the following example of NetScaler firmware upgrade.

```
login: nsroot

Password: nsroot

Last login: Mon Apr 17 15:05:05 2018 from 10.252.243.134
```

Upgrade a NetScaler standalone appliance by using the NITRO API

To use NITRO API to upgrade or downgrade a NetScaler, see Automate NetScaler Upgrade and Downgrade with a Single API.

Verify entities status on the NetScaler appliance after upgrading

After the NetScaler appliance is upgraded, verify the status of the following entities:

- Virtual servers are in UP state
- Monitors are in UP state
- GSLB sites synchronize without any issues
- All certificates are present on the appliance
- All the licenses are present on the appliance

Check and install NetScaler 14.1 software update

Update the NetScaler software when an update is available, for better performance. A NetScaler update can include feature improvements, performance fixes, or enhancements. Make sure that you read the release notes to see what fixes and enhancements are available in the update. To check and install a software update, do the following.

1. In the NetScaler home page, click **Check for Update** from the **nsroot** menu at the top right corner.
2. In the **Latest System Software Updates Available** page, check the available software update that you can install.
3. Click **Download** to download the installation package from the NetScaler download website.
4. After you have downloaded the software package, install the update through either CLI or GUI procedure.

NOTE:

The **Check for Update** link is accessible only if you log into the GUI through the HTTP protocol and not through the HTTPS protocol.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Related resources

The following resources provide related information about upgrading or downgrading a NetScaler appliance:

- Video tutorial - How to upgrade your NetScaler using CLI
- You can also upgrade NetScaler by using the following methods:
  - In Service Software Upgrade.
  - Upgrade jobs.

Downgrade a NetScaler standalone appliance

You can downgrade to any earlier release on a standalone NetScaler by using the CLI.

NOTE:

Loss in configuration might occur when downgrading. Compare the configurations before and after the downgrade, and then manually reenter any missing entries.

Downgrade a NetScaler appliance by using the CLI

Follow the steps given below to downgrade a NetScaler standalone appliance running release 14.1 to an earlier release.

In this procedure, `<release>` and `<releasenumber>` represent the release version you are downgrading to, and `<targetbuildnumber>` represents the build number that you are downgrading to.

1. Open an SSH connection to the NetScaler by using an SSH client, such as PuTTY.
2. Log on to the NetScaler by using the administrator credentials. Save the running configuration. At the prompt, type:

   save config
3. Create a copy of the ns.conf file. At the shell prompt, type:

   a. `cd /nsconfig`

   b. `cp ns.conf ns.conf.NS<currentbuildnumber>`

   You should backup a copy of the configuration file on another computer.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Copy the \<releasenumber\> configuration file (ns.conf.NS\<releasenumber\>) to ns.conf. At the shell prompt, type:

   ```
   cp ns.conf.NS<releasenumber> ns.conf
   ```

   NOTE:

   `ns.conf.NS<releasenumber>` is the backup configuration file that is automatically created when the system software is upgraded from release version `<releasenumber>` to the current release version.

   There may be some loss in configuration when downgrading. After the appliance restarts, compare the configuration saved in step 3 with the running configuration, and make any adjustments for features and entities configured before the downgrade. Save the running configuration after making the changes.

   Important:

   If routing is enabled, perform step 5. Otherwise, skip to step 6.

5. If routing is enabled, the ZebOS.conf file contains the configuration. At the shell prompt, type:

   ```
   cd /nsconfig

   cp ZebOS.conf ZebOS.conf.NS

   cp ZebOS.conf.NS<targetreleasenumber> ZebOS.conf
   ```

6. Change directory to `/var/nsinstall/<releasenumber>nsinstall`, or create one if it does not exist.
7. Change directory to `build_<targetbuildnumber>`, or create one if it does not exist.
8. Download or copy the installation package (`build-<release>-<targetbuildnumber>.tgz`) to this directory and extract the contents of the installation package.
9. Run the `installns` script to install the new version of the system software. The script updates the `/etc` directory.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTES:

- **NetScaler version 14-1 build 12.35 or earlier**: You might see a prompt to load the configuration file if the configuration file for the build you are downgrading to does not exist. You can select a different configuration file from the list and downgrade the system software.
- **NetScaler version 14-1 build 17.x or later**: The downgrade fails if the configuration file for the build you are downgrading to does not exist. You must use the `./installns -a` command to select the configuration file and then downgrade the system software manually.

If the free space available on the flash drive is insufficient to install the new build, the NetScaler aborts the installation. Manually clean up the flash drive and restart the installation.

Example:

```
login: nsroot

Password: nsroot

Last login: Mon Apr 24 02:06:52 2017 from 10.102.29.9

Done

> save config

> shell

```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
root@NSnnn# cp ns.conf.NS10.5 ns.conf

root@NSnnn# cd /var/nsinstall

root@NSnnn# mkdir 10.5nsinstall

root@NSnnn# cd 10.5nsinstall

root@NSnnn# mkdir build_57

root@NSnnn# cd build_57

root@NSnnn# ftp 10.102.1.1

ftp> mget build-10.5-57_nc.tgz

ftp> bye

root@NSnnn# tar -xzvf build-10.1-125_nc.tgz

root@NSnnn# ./installns
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
installns version (10.5-57) kernel (ns-10.5-57.gz)

...

...

...

Copying ns-10.5-57.gz to /flash/ns-10.5-57_nc.gz ...

Changing /flash/boot/loader.conf for ns-10.5-57 ...

Installation has completed.

Reboot NOW? [Y/N] Y
```

Upgrade a high availability pair

One of the requirements of NetScaler in a high availability setup is to install the same NetScaler software version (Release) on both the primary and secondary nodes. Therefore, ensure that the software is upgraded on both nodes.

You can follow the same procedure as upgrading a standalone instance to upgrade both the nodes in a high availability pair, although other considerations apply to upgrading a high availability pair.

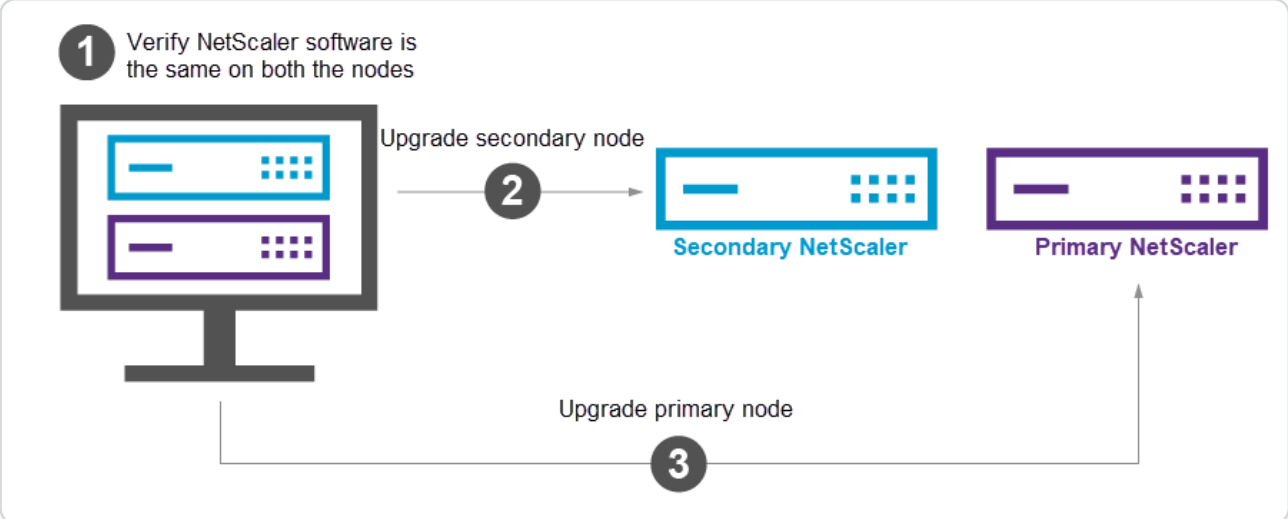
Before you start a NetScaler firmware upgrade on an HA pair, read the prerequisites mentioned in the Before you begin section. Also, you need to consider a few HA-specific points.

Points to note

IMPORTANT:

It's important that both the upgrade changes and your customizations are applied to an upgraded NetScaler. Therefore, if you have customized configuration files in the `/etc` directory, see Upgrade considerations for customized configuration files before you continue with the upgrade.

- Upgrade the secondary node first and then the primary node. You can upgrade NetScaler using the CLI or GUI.



- If both the nodes in an HA setup are running different NetScaler software versions, the following functionalities are disabled:
    - HA config synchronization

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- HA command propagation
- HA synchronization of state service information
- Connection mirroring (connection failover) of sessions
- HA synchronization of persistence sessions information

NOTES:

The functionality behavior changes as follows when both the nodes are running different builds (for example 8.x and 4.x) of the same NetScaler software release (for example 14.1):

- These functionalities are disabled if both the builds have different internal HA versions.
- These functionalities work fine if both the builds have the same internal HA versions.

Refer to the New internal HA version in NetScaler builds section to check if the internal HA version has changed in a NetScaler build.

- Synchronization of the files in the `All` mode of the `sync HA files` command works successfully if the two nodes in an HA configuration are running different NetScaler software versions, or the two nodes are running different builds of the same version. For more information, see synchronizing Configuration Files in High Availability Setup.

New internal HA version in NetScaler® builds

The following table lists the NetScaler® builds in which the internal HA version has changed:

RELEASE 14.1	RELEASE 13.1	RELEASE 12.1
Build 43.50	Build 57.26	Build 65.35
Build 38.53	Build 54.29	Build 62.27
Build 34.42	Build 53.24	Build 61.19
Build 29.72	Build 51.15	Build 60.19
Build 25.56	Build 50.23	Build 59.16
Build 21.57	Build 49.15	Build 58.15

	Build 17.42	
	Build 12.51	
	Build 9.60	
	Build 4.44	

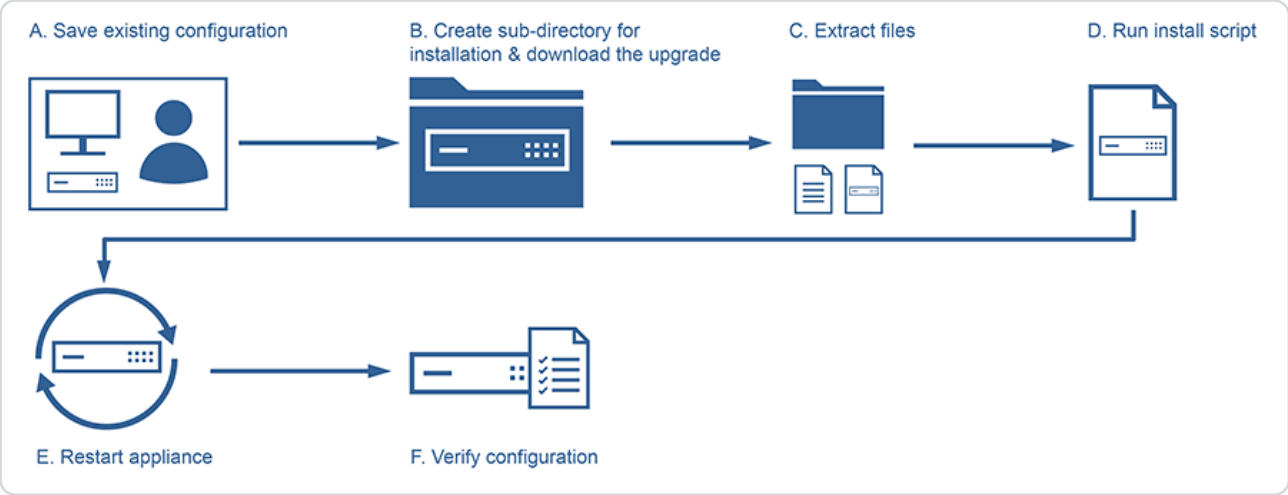
Overview of the high availability pair upgrade process

The HA pair upgrade process includes the following steps:

1. Upgrade software on the secondary node.
2. Upgrade software on the primary node.

The following illustration shows the procedure to upgrade software on the node:

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Upgrade software on the secondary node by using the CLI

1. Upgrade the secondary node as described in Upgrade a NetScaler standalone appliance using the CLI.
2. Log in to the NetScaler CLI using the `nsroot` credentials.
3. Run the following command to display the state of NetScaler.

   ```
   show ha node
   ```

   The command output must show that the node is a secondary node and synchronization is disabled.
4. Run the following command to perform a force failover and takeover as primary node:

   ```
   force failover
   ```

5. Verify that the node is now a primary node.

   Here's a sample configuration in the new primary node.

   ```
   login: nsroot

   Password: nsroot

   Last login: Monday Apr  17 08:37:26 2017 from 10.102.29.9

   Done
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show ha node

        2 nodes:

        Node ID:      0

        IP:        10.0.4.2

        Node State: UP

        Master State: Primary

        ...

        Sync State: AUTO DISABLED

        Propagation: AUTO DISABLED

        ...

Done
```

Upgrade software on the primary node by using the CLI

NOTE:

After completing the "Upgrade software on the secondary node" procedure, the original primary node is now a secondary node.

1. Upgrade the secondary node as described in Upgrade a NetScaler standalone appliance using the CLI.
2. Log in to the NetScaler CLI using the `nsroot` credentials.
3. Run the following command to display the state of the NetScaler.

   ```
   show ha node
   ```

   The command output must show that the node is a secondary node and the status of the node as UP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Run the following command to perform a force failover to ensure that the node is a primary node:

```
force failover
```

5. Verify that the node is a primary node.

   Here's an example configuration of the new primary node and the new secondary node.

```
show ha node

    Node ID:      0

    IP:   10.0.4.11

    Node State: UP

    Master State: Primary

    ...

    ...

    INC State: DISABLED

    Sync State: ENABLED

    Propagation: ENABLED

    Enabled Interfaces : 1/1

    Disabled Interfaces : None

    HA MON ON Interfaces : 1/1

    ...

    ...

    Local node information

    Critical Interfaces: 1/1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

Show ha node

    Node ID:      0

    IP:   10.0.4.2

    Node State: UP

    Master State: Secondary

    ..

    ..

    INC State: DISABLED

    Sync State: SUCCESS

    Propagation: ENABLED

    Enabled Interfaces : 1/1

    Disabled Interfaces : None

    HA MON ON Interfaces : 1/1

    . .

    . .

    Local node information:

    Critical Interfaces: 1/1

Done
```

Upgrade a high availability pair by using the GUI

Follow these steps to upgrade a NetScaler pair in a high availability setup, by using the ADC GUI. Consider an example of a high availability setup of NetScaler instances: NetScaler-A (primary) and NetScaler-B (secondary).

1. **Upgrade the secondary node**. Log in to the secondary node GUI using administrator credentials, and upgrade the node as described in Upgrade a NetScaler standalone appliance by using the GUI.
2. **Force failover**. Perform a force failover on the secondary node using the GUI as described in Forcing a node to fail over.

   After failover operation, the secondary node takes over as primary and the primary node becomes the new secondary node. After the failover operation in the example HA setup:

   - NetScaler-B becomes the new primary
   - NetScaler-A becomes the new secondary
3. **Upgrade the original primary node (new secondary node)**. Log in to the new secondary node GUI (NetScaler-A) and upgrade the node as described in Upgrade a NetScaler standalone appliance by using the GUI.
4. **Force failover**. Perform a force failover on the new secondary node (NetScaler-A) using the GUI as described in Forcing a node to fail over.

   After this second failover operation, the state of both the nodes returns to the same state as before starting the HA upgrade operation. After the failover operation in the example HA setup:

   - NetScaler-A becomes primary
   - NetScaler-B becomes secondary
5. **Verify the upgrade process**. Log in to the GUI of both the nodes. Navigate to **System > High Availability**, on the details page. Verify the HA state of both the nodes. Also, verify the upgraded version details displayed on the top pane of the GUI.

How to upgrade a high availability setup by using the GUI

<iframe src="https://www.youtube.com/embed/F_58_P4gqtg" width="720px" height="480px" frameborder="0" title="YouTube video player" allowfullscreen=""> </iframe>

In Service Software Upgrade support for high availability for performing zero downtime upgrade

During a regular upgrade process in a high availability (HA) setup, at some point, both nodes run different software builds. These two builds can have the same or different internal HA version numbers.

If both the builds have different HA version numbers, connection failover (even if it is enabled) for existing data connections is not supported. In other words, all existing data connections are lost, which leads to downtime.

To address this issue, in Service Software Upgrade (ISSU) can be used for HA set-ups. ISSU introduces a migration functionality, which replaces the force failover operation step in the upgrade process. The migration functionality takes care of honoring the existing connections and includes the force failover operation.

After a migration operation is performed, the new primary node always receives traffic (request and response) related to the existing connections but steers them to the old primary node. The old primary node processes the data traffic and then sends them directly to the destination.

How the enhanced ISSU works

The regular upgrade process in an HA setup consists of the following steps:

1. **Upgrade the secondary node**. This step includes software upgrade of the secondary node and restart of the node.
2. **Force Failover**. Running the force failover makes the upgraded secondary node to primary, and the primary node to secondary.
3. **Upgrade the new secondary node**. This step includes software upgrade of the new secondary node and restart of the node.

During the time frame between step 1 and step 3, both nodes run different software builds. These two builds can have the same or different internal HA versions.

If both the builds have different HA version numbers, connection failover (even if it is enabled) for existing data connections is not supported. In other words, all existing data connections are lost, which leads to downtime.

The ISSU upgrade process in an HA setup consists of the following steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. **Upgrade the secondary node**. This step includes software upgrade of the secondary node and restart of the node.
2. **ISSU migration operation**. The step includes the force failover operation and takes care of the existing connections. After you perform the migration operation, the new primary node always receives traffic (request and response) related to the existing connections but steers them to the old primary node through the configured SYNC VLAN (if configured) in the GRE tunnel. The old primary node processes the data traffic and then sends them directly to the destination. The ISSU migration operation is completed when all the existing connections are closed.
3. **Upgrade the new secondary node**. This step includes software upgrade of the new secondary node and restart of the node.

Before you begin

Before you start performing the ISSU process in an HA setup, go through the following pre-requisites, limitations, and points to note:

- Ensure that the capacity of the interface, where the MAC address of the peer NSIP address is resolved, is equal to or greater than the capacity of the client or server interface. For example, consider the following scenarios:
  - The MAC address of the peer NSIP address is resolved on the interface 1/x, and the data interface is 10/x. In this scenario, you must not perform ISSU because the capacity of the interface on which the MAC address is resolved is less than that of the data interface.
  - The MAC address of the peer NSIP address is resolved on the interface 10/x, and the data interface is 10/x. In this scenario, you can perform ISSU because the capacity of the interface on which the MAC address is resolved is the same as the data interface.
- Ensure the `SYNC VLAN` is configured on both the nodes of the HA setup. For more information, see Restricting high availability synchronization traffic to a VLAN.

NOTE:

SYNC VLAN configuration is supported only in L2 HA. It is not supported for HA-INC mode.

- ISSU is not supported on the Microsoft Azure cloud because Microsoft Azure does not support GRE tunneling.
- HA config propagation and synchronization do not work during ISSU.
- ISSU is not supported for IPv6 HA setup.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- ISSU is not supported with admin partitions.
- ISSU is not supported for the following sessions:
  - Jumbo frames
  - IPv6 sessions
  - Large scale NAT (LSN)
- In an HA setup in INC mode, ISSU migration operation migrates only the client side connections. The migration of server-side connections is not required because both the HA nodes have independent SNIP configurations.
- For SYNC VLAN configuration, it is recommended to increase the SYNC VLAN MTU by at least 42 bytes.

Configuration steps

ISSU includes a migration feature, which replaces the force failover operation in the regular upgrade process of an HA setup. The migration functionality takes care of honoring the existing connections and includes the force failover operation.

During the ISSU process of an HA setup, you run the migration operation just after you upgraded the secondary node. You can perform the migration operation from either of the two nodes.

CLI Procedure

To perform the HA migration operation by using the CLI:

At the command prompt type:

```
start ns migration
```

GUI Procedure

To perform the HA migration operation by using the GUI:

Navigate to **System > System Information > Migration tab**. Click **Start Migration**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Display ISSU statistics

You can view the ISSU statistics for monitoring the current ISSU process in an HA setup. The ISSU statistics displays the following information:

- Current status of ISSU migration operation
- Start time of the ISSU migration operation
- End time of the ISSU migration operation
- Start time of the ISSU rollback operation
- Total number of connections that are processed as part of ISSU migration operation
- Number of remaining connections that are being processed as part of ISSU migration operation

You can view the ISSU statistics on either of the HA nodes by using the CLI or GUI.

CLI Procedure

To display the ISSU statistics by using the CLI:

At the command prompt type:

```
show ns migration
```

GUI Procedure

To display the ISSU statistics by using the GUI:

Navigate to **System > System Information > Migration tab**. Click **Click to show migration details**.

Display ISSU statistics - the list of existing connections that the old primary node is processing

You can display the list of existing connections that the old primary node is serving as part of the ISSU migration operation by using the `dumpsession` (`Dump Session`) option of the `show migration` operation.

The show migration operation with the `dumpsession` option must be run only on the new primary node during the ISSU operation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CLI Procedure

To display the list of existing connections that the old primary node is processing by using the CLI:

At the command prompt type:

```
show ns migration –dumpsession YES
```

```
> sh migration -dumpsession yes

Index   remote-IP-port          local-IP-port           idle-time(x 10ms)

1       192.0.2.10      22      192.0.2.1       15998       703

2       198.51.100.20   7375    98.51.100.2     22          687

3       203.0.113.30    5506    203.0.113.3     22          687
```

GUI Procedure

To display the list of existing connections that the old primary node is processing by using the GUI:

Navigate to **System > System Information > Migration tab**. Click **Click to show migration connections**.

Force completion of ISSU migration

During ISSU upgrades, NetScaler® waits for existing connections to naturally close before completing the migration. However, some connections might be long-lived and prevent the migration from proceeding to completion.

From NetScaler release 14.1-47.x, the "Force ISSU Migration Completion" feature allows administrators to force the completion of ISSU migration by terminating long-lived active connections. The management-related sessions, such as CLI, GUI, and Console connections, are

© 1997–2026 Citrix Systems, Inc. All rights reserved.

excluded from migration to ensure uninterrupted access. This enhancement improves the efficiency and reliability of ISSU processes.

This feature can be used in the following scenarios:

- When migration is "in progress" and waiting for connections to close.
- When rollback is "in progress" and waiting for connections to close.

Force completion of ISSU migration by using the CLI

At the command prompt, type:

```
complete ns migration
```

Force completion of ISSU migration by using the GUI

1. Navigate to **System > System Information > Migration** tab.
2. Click **Complete Migration** to terminate active migrated connections and mark the migration status as "Complete."

Rollback of the ISSU process

HA setups now support rollback of the In Service Software Upgrade (ISSU) process. The ISSU rollback feature is helpful if you observe that the HA setup during the ISSU migration operation is not stable, or is not performing at an optimum level as expected.

The ISSU rollback is applicable when the ISSU migration operation is in progress. The ISSU rollback does not work if the ISSU migration operation is already completed. In other words, you must run the ISSU rollback operation when the ISSU migration operation is in progress.

The ISSU rollback functions differently based on the state of the ISSU migration operation when the ISSU rollback operation is triggered:

- **Force failover has not yet happened during the ISSU migration operation**. The ISSU rollback stops the ISSU migration operation, and removes any internal data related to the ISSU migration stored in both the nodes. The current primary node remains as the primary node and continues to process data traffic related to existing and new connections.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Force failover has happened during ISSU migration operation**. If the HA failover has happened during the ISSU migration operation, then the new primary node (say it is N1) processes traffic related to the new connections. The old primary node (new secondary node, say it is N2) processes traffic related to the old connections (existing connections before the ISSU migration operation).

  The ISSU rollback stops the ISSU migration operation and triggers a force failover. The new primary node (N2) now starts processing traffic related to the new connections. The new primary node (N2) also continues to process traffic related to old connections (existing connections established before the ISSU migration operation). In other words, the existing connections established before the ISSU migration operation are not lost.

  The new secondary node (N1) removes all the existing connections (new connections created during the ISSU migration operation) and does not process any traffic. In other words, any existing connections that were established after the force failover of the ISSU migration operation are lost forever.

Configuration steps

You can use the NetScaler CLI or GUI to perform the ISSU rollback operation.

CLI Procedure

To perform the ISSU rollback operation by using the CLI:

At the command prompt type:

```
stop ns migration
```

GUI Procedure

To perform the ISSU rollback operation by using the GUI:

Navigate to **System > System Information > Migration tab**. Click **Stop Migration**.

SNMP traps for In Service Software Upgrade process

The In Service Software Upgrade (ISSU) process for an HA setup supports the following SNMP trap messages at the start and end of the ISSU migration operation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SNMP TRAP	DESCRIPTION
migrationStarted	This SNMP trap is generated and sent to the configured SNMP trap listeners when the ISSU migration operation starts.
migrationComplete	This SNMP trap is generated and sent to the configured SNMP trap listeners when the ISSU migration operation completes.

The primary node (before the start of the ISSU process) always generates these two SNMP traps and sends them to the configured SNMP trap listeners.

There are no SNMP alarms associated with the ISSU SNMP traps. In other words, these traps are generated irrespective of any SNMP alarm. You only have to configure the trap SNMP listeners.

For more information on configuring SNMP trap listeners, see SNMP traps on NetScaler.

Downgrade a high availability pair

You can downgrade to any release on a high availability pair by using the command line interface. The GUI does not support the downgrade process.

To downgrade the system software on a NetScaler pair in a high availability pair, you need to downgrade the software first on the secondary node and then on the primary node. For instructions on downgrading each node separately, see Downgrade a NetScaler standalone appliance.

IMPORTANT

Loss in configuration might occur when downgrading. You should compare the configurations before and after the downgrade, and then manually re-enter any missing entries.

Troubleshooting issues related to the installation, upgrade, and downgrade processes

If the appliance does not work as expected after you complete the installation, upgrade, or downgrade process, the first thing to do is to check for the most common causes of the problem.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Resources for troubleshooting

For best results, use the following resources to troubleshoot an issue related to installing, upgrading, or downgrading a NetScaler:

- The configuration files from the appliance. In case of a High Availability pair, the configuration files from both appliances.
- The following files from the appliance(s):
  - The relevant newnslog files.
  - The ns.log file.
  - The messages file.
- A network topology diagram.

Issues and resolutions

Following are the most common installation, upgrade, and downgrade issues, and tips for resolving them:

1. **Issue**

   Upgrading a NetScaler MPX appliance fails due to hardware and software incompatibility.

   Resolution

   See the NetScaler MPX hardware-software compatibility matrix and check whether the software release is supported on the NetScaler MPX hardware.

2. **Issue**

   Upgrading a NetScaler VPX appliance fails due to NetScaler VPX appliance and hypervisor incompatibility.

   Resolution

   See the NetScaler VPX appliance and hypervisor compatibility matrix and check whether the NetScaler VPX appliance model is supported on the hypervisor.

3. **Issue**

   Upgrading a NetScaler appliance fails due to hardware errors.

   Resolution

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Validate the integrity of the NetScaler appliance. If you have a NetScaler hardware appliance, Citrix recommends running `fsck` for running a disk check and validating the integrity of the NetScaler hard drive.

For more information, see How to Verify the File System Integrity of a NetScaler appliance.

4. **Issue**

   Upgrading a NetScaler appliance by using the GUI stalls.

   Resolution

   Refresh the browser to check whether the upgrade is progressing or not.

5. **Issue**

   Upgrading a NetScaler appliance fails due to low Space in /var Directory

   Resolution

   Free up space on the /var directory. For more information, see Refer to How to free space on /var directory.

6. **Issue**

   The NetScaler is not accessible after the software downgrade

   Cause

   During the software downgrade process, if the configuration file of the existing release and build does not match the configuration file of the earlier release and build, the appliance cannot load the configuration, and the default IP address is assigned to the appliance.

   Resolution

   - Verify that the appliance is accessible from the console.
   - Verify the NSIP address and the routes on the appliance.
     - If the IP address has changed to the default 192.168.100.1 IP address, change the IP address as required.
     - Verify that the appliance is accessible.

7. **Issue**

   During an upgrade, if I run the command for synchronizing, the following message appears:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Command failed on the secondary node but succeeded on the primary node.

Resolution

Do not run any dependent commands (set /unset /bind /unbind) when High Availability (HA) synchronization is in progress.

8. **Issue**

   During an upgrade process, traffic does not pass through the new primary node when you run the force failover command.

   Resolution

   - Check for problems with the network topology and the switch configurations.
   - Run the set L2param -garpreply ENABLED command to enable the GARP reply.
   - Try using virtual MAC if not already used.
   - Run the sendarp –a command from the primary node.

9. **Issue**

   After upgrading or downgrading a NetScaler appliance, connecting to the appliance fails through SSH.

   Resolution

   Perform the following operations in the NetScaler appliance:

   - Remove old or insecure host keys at `/nsconfig/ssh/ssh_host_*`.
   - Review the custom SSHD configuration at `/nsconfig/sshd_config` and check if it is still relevant and compatible. Rename or remove the custom SSHD configuration accordingly.
   - Cold reboot the NetScaler appliance

10. **Issue**

    In an HA pair, after you run the force HA failover command the devices keep rebooting. The secondary device does not come up after an upgrade.

    Resolution

    Check to see if the /var directory is full. If so, remove the old installation files. Run the df –h command to show the available disk space.

11. **Issue**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

After upgrading an HA pair, one of the nodes is listed as state UNKNOWN.

Resolution

- Check to see if both nodes are running the same build. If the builds are not same and HA nodes have a version mismatch, some of the fields are shown as UNKNOWN when you run the show ha node command.
- Check to see if the secondary appliance is reachable.

12. **Issue**

    After you upgrade the NetScaler, the interface shows most of the load balancing virtual servers and services are DOWN.

    Resolution

    Verify that the SNIP address is active on the secondary appliance. Also, type the show service command to see if the service is running.

13. **Issue**

    After performing an upgrade, all virtual servers are down on the secondary appliance.

    Resolution

    Enable the HA state and HA synchronization by running the following commands:

    - set node hastate enable
    - set node hasync enable

    Disabling HA is not recommended.

14. **Issue**

    After performing a downgrade, the NetScaler does not boot up properly.

    Resolution

    Check to see if the correct license has been installed.

15. **Issue**

    In an HA pair, some features do not get synchronized after an upgrade is performed.

    Resolution

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Run the sync ha file misc command to synchronize the configurations files from the primary node to secondary node.

16. **Issue**

    During reboot, the following error message appears:

    One or more commands in ns.conf failedWhat should I do?

    Resolution

    Make sure that no command in the ns.conf file exceeds the 255 byte limit. In commands that create policies that are too long for the 255-byte limit, you can use pattern sets to shorten the policies.

    Example:

    ```
    add cs policy p11 -rule
    'HTTP.REQ.URL.ENDSWITH_ANY("ctx_file_extensions")'

    Done
    ```

    ctx_file_extensions is a default patset that covers a large number of extensions. In addition to the default pattern sets, you can create user-defined pattern sets. Add a patset by running the following command:

    ```
    add patset <name>
    ```

    Note: Patsets are supported only in release 9.3 or later.

17. **Issue**

    When upgrading a NetScaler VPX appliance, I am told to free up space in /var. What files do I remove?

    Resolution

    Remove the old installation files from /var/tmp/ directory. Also remove unwanted files from /flash.

18. **Issue**

    There is no connectivity to the graphical user interface (GUI) when you run the force HA failover command on the secondary appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Resolution

Log on to the secondary appliance using the command line interface and enable the access to GUI by running the set ns ip \<IP\> -gui enabled command.

19. **Issue**

    After performing an upgrade, and when I click on any link on the GUI that has to load a java applet (Upgrade Wizard or license Wizard), the following error message appears: **GUI version does not match with the kernel version. Please close this instance, clear java plug-in cache and reopen**.

    Resolution

    - Log on to the NetScaler using the GUI.
    - Navigate to NetScaler Gateway \> Global Settings.
    - Click Change Global Settings under Settings.
    - In the details pane, under Client Experience, select Default from the UI theme list.
    - Click OK.

20. **Issue**

    If upgrading a NetScaler appliance failed because of any reason, how to restore the appliance using the backed-up files?

    Resolution

    If the upgrade is unsuccessful then restore the appliance to the previous version of the NetScaler appliance using the backed-up files. For more information, see Backup and restore a NetScaler appliance.

    For more information on backup and restore of a NetScaler cluster setup, see Backup and restore of a cluster setup.

21. **Issue**

    If licenses are missing after a failed upgrade of a NetScaler appliance, how to resolve the issue?

    Resolution

    If any license goes missing or if you want to reallocate the licenses, refer to the following topic Licensing overview.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

These troubleshooting steps also apply to issues with configuration loss when downgrading the software across multiple releases.

For any other issue, see the release notes, Knowledge Center articles, and FAQs.

FAQs

For answers to the questions that you might have about upgrading the NetScaler firmware, see the Installing, Upgrading, and Downgrading FAQs.

New and deprecated commands, parameters, and SNMP OIDs

This section lists the new and deprecated commands, parameters, and SNMP OIDs.

New parameters

The following table lists the new commands in release 14.1.

COMMAND GROUP	COMMANDS AND PARAMETERS
Application Firewall	`bind appfw profile <name> [-grpcValidation <string> ]`; `bind appfw profile <name> [-restValidation]`; `unbind appfw profile <name> [-grpcValidation <string>]`; `unbind appfw profile <name> [-restValidation <string>]`; `show appfw profile [grpcValidation]`; `show appfw profile [restvalidation]`
NS	`show ns httpProfile [-http3WebTransport]`; `add ns httpProfile [-http3WebTransport ( ENABLED | DISABLED)`; `set ns httpProfile [-http3WebTransport ( ENABLED | DISABLED)]`; `rm ns httpProfile [-http3WebTransport]`;

© 1997–2026 Citrix Systems, Inc. All rights reserved.

COMMAND GROUP	COMMANDS AND PARAMETERS
	`unset ns httpProfile [-http3WebTransport]`; `add vpn vserver <name> <servicetype> [-quicProfileName <strings>]`; `set vpn vserver <name>[-quicProfileName <strings>]`; `unset vpn vserver <name> [-quicProfileName]`; `add ns tcpProfile <name> [-rfc5961Compliance ( ENABLED | DISABLED)]`; `set ns tcpProfile <name> [-rfc5961Compliance ( ENABLED | DISABLED)]`; `unset ns tcpProfile <name> [-rfc5961Compliance]`; `show ns tcpProfile <name> [rfc5961Compliance]`; `set ns tcpParam [-rfc5961ChlgAckLimit <positive_integer>]`; `show ns tcpParam` [rfc5961ChlgAckLimit]
Policy	`add policy patset <name> [-dynamic (YES | NO)]`; `set policy patset [-dynamic (YES | NO)]`; `show policy patset [<name>] [-dynamicOnly]`; `add policy dataset <name> <type> [-dynamic (Yes | NO)]`; `set policy dataset <name> [-dynamic (Yes | NO)]`; `show policy dataset <name> [-dynamicOnly]`; `show policy dataset`
API	`show api specfile [<name>]`
HA	`add HA node <id> <IPAddress> [-rpcnodepassword]`
Utility	`show techsupport [-authtoken <string>]`

Solutions for Telecom Service Providers

Information and Communication Technology (ICT) is about bringing the Internet user closer to the apps and data. The latest datacenter technologies have enabled the user, apps and data to be located anywhere. A user can access apps and data from the office or from home, or from a location such as an airport. The apps and data can be located either on the enterprise's premises, in a public or private cloud, or on a hybrid host. The result has been on only increased productivity, but also reduced costs of ownership and maintenance.

Service provides offer the core infrastructure needed for carrying the user's apps and data over the network. Because the core infrastructure serves millions of subscribers and a wide variety of apps and data, requirements for scale and protocol support are very high. The core infrastructure handles two major types of traffic: data plane and control plane. Each of these planes has its own scale and protocol-support requirements.

The data plane is the part of the core infrastructure that carries user apps and data from end to end, that is, between end-user equipment and the application server. The number of users accessing apps and data is in the thousands of millions, so throughput and IP-addressing requirements are very high. Every user in the network must be uniquely identifiable. Only then can the service provider control the traffic, monitor network usage, deliver user-specific services, and log information correctly. Many of the today's client devices and application servers support IPv6 natively. The core infrastructure must not only support a mix of IPv4 and IPv6 clients and servers, but also provide the technologies for cross-communication between IPv4 and IPv6. Finally, a service provider is measured by the quality of service (directly related to end-user experience) and the availability of service without disruptions. The data plane should be resilient enough to provide both quality and availability at the same time.

The control-plane infrastructure manages user traffic and maintains the business and network operations services. The most important of the many protocols that run in this plane are Diameter, Radius, and SMPP. Diameter is a base protocol over which several other function-specific protocols have been developed. For example:

- Gx interface between the Policy and Charging Enforcement Function (PCEF) and the Policy and Charging Rules Function (PCRF)
- Gy interface between the Online Charging System (OCS) and the Cisco Packet Data Network Gateway (PGW)/Policy and Charging Enforcement Function (PCEF)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The volume of control plane traffic is in direct proportion to user activity. To manage the control plane traffic, service providers use several ADC functionalities, such as load balancing and content switching. They need fine-grain control of control plane traffic, which equals data-plane traffic in complexity.

Service providers must meet demanding service-level agreements (SLAs), and are scrutinized thoroughly by regulators for compliance. Adhering to requirements while managing the data and control plane traffic requires a service provider to keep its infrastructure nimble, within budget, easily upgradable, and flexible. As the most powerful and advanced ADCs in the market today, NetScaler products are a natural fit for the service-provider environment.

Large Scale NAT

NOTE:

Large Scale NAT (LSN) feature is deprecated from NetScaler 14.1 release onwards.

Deprecated features are not removed immediately. The NetScaler® appliance continues to support the deprecated feature until it is removed in a future release.
The Internet’s phenomenal growth has resulted in a shortage of public IPv4 addresses. Large Scale NAT (LSN/CGNAT) provides a solution to this issue, maximizing the use of available public IPv4 addresses by sharing a few public IPv4 addresses among a large pool of Internet users.

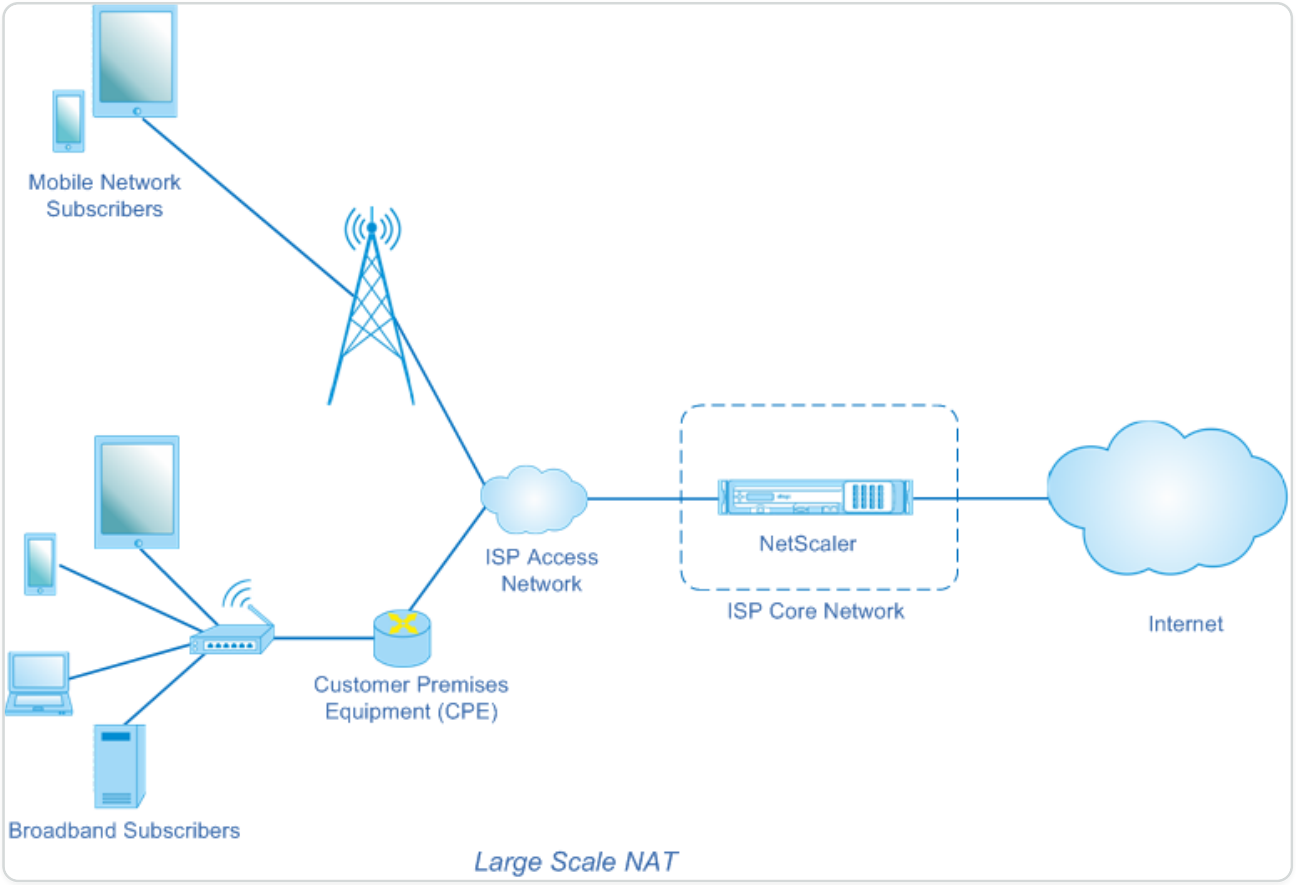
LSN translates private IPv4 addresses into public IPv4 addresses. It includes network address and port translation methods to aggregate many private IP addresses into fewer public IPv4 addresses. LSN is designed to handle NAT on a large scale. The NetScaler LSN feature is very useful for Internet Service Providers (ISPs) and carriers providing millions of translations to support a large number of users (subscribers) and at very high throughput.

LSN Architecture

The LSN architecture of an ISP using NetScaler products consists of subscribers (Internet users) in private address spaces accessing the Internet through a NetScaler appliance deployed in ISP’s core network. Subscribers are connected to the ISP through the ISP's access network. Usually, subscribers for commercial use of the Internet are directly connected to the ISP's access network. Serving those subscribers requires only one level of NAT (NAT44).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Noncommercial subscribers, however, are typically behind customer-premises equipment (CPE), such as routers and modems, that also implements NAT. These two levels of NAT create the NAT444 model. Deploying a NetScaler appliance in an ISP's core network for LSN functionality is transparent to the subscribers and requires no configuration changes to subscribers or the CPEs.



Large Scale NAT

The NetScaler appliance receives all subscriber packets destined to the Internet. The appliance is configured with a pool of pre-defined NAT IP addresses to use for LSN. The NetScaler appliance uses its LSN feature to translate the source IP address (private) and port of the packet to the NAT IP address (public) and NAT port, and then sends the packet to its destination on the Internet. The appliance maintains a record of all active sessions that use the LSN feature. These sessions are called LSN sessions. The NetScaler appliance also maintains the mappings between subscriber IP address and port, and NAT IP address and port, for each session. These mappings are called LSN mappings. From LSN sessions and LSN mappings, the NetScaler appliance recognizes a response packet (received from the Internet) belonging to a particular session. The appliance translates the destination IP address and port of the response packet from NAT IP address:port to the subscriber IP address:port, and sends the translated packet to the subscriber.

LSN Features Supported on NetScaler appliance

The following describes some of the LSN features supported on NetScaler appliance:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NAT Resource Allocation

The NetScaler appliance allocates NAT IP addresses and ports, from its pre-defined NAT resource pool, to subscribers to translate their packets for transmission to external hosts (Internet). The NetScaler appliance supports the following types of NAT IP address and port allocation for subscribers:

- **Deterministic.** The NetScaler appliance allocates a NAT IP address and a block of ports to each subscriber. The appliance sequentially allocates NAT resources to these subscribers. It assigns the first block of ports on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT address is assigned to the subscriber, and so on.

  The NetScaler appliance logs the allocated NAT IP address and the port block for a subscriber. For a connection, a subscriber can be identified just by its mapped NAT IP address and port block. Because of this reason, the NetScaler appliance does not log any LSN session created or deleted. If the entire block of ports is being used, the NetScaler appliance drops any new connection from the subscriber.
- **Dynamic.** The NetScaler appliance allocates a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. When port block allocation is enabled in the configuration, the appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The NetScaler appliance then allocates this NAT IP address and one of the ports from the allocated block to each subsequent connection from this subscriber. If the entire block of ports is being used, the appliance allocates a new random port block to the subscriber when it initiates a new connection. One of the port in the new port block is allocated for the new connection.

IP Pooling

The following NAT resource allocation options are available for subsequent sessions of a subscriber who was allocated a random NAT IP address and port for an existing session.

- **Paired.** The NetScaler appliance allocates the same NAT IP address for all sessions associated with the same subscriber. When no more ports are available for that address, the appliance drops any new connections from the subscriber. This option is needed for proper functioning of certain applications that require creation of multiple sessions on the same source IP address (for example in peer-to-peer applications that use RTP or RTCP protocol.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Random.** The NetScaler appliance allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

Reusing LSN Mappings

The NetScaler appliance can reuse an existing LSN map for new connections originating from the same subscriber IP address and port. The NetScaler LSN feature supports the following types of LSN mapping reuse:

1. **Endpoint Independent.** The NetScaler appliance reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port. This type of LSN map reuse is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The NetScaler appliance reuses the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
3. **Address port dependent.** The NetScaler appliance reuses the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

LSN Filtering

The NetScaler appliance can filter packets from external hosts based on the active LSN sessions and LSN mappings. Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y). The NetScaler LSN feature supports the following types of filtering:

1. **Endpoint Independent.** The NetScaler appliance filters out only those packets that are not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x), regardless of the external host IP address and port source (Z:z). The NetScaler appliance forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external host to the subscriber. This type of filtering is useful for proper functioning of VOIP and peer-to-peer applications.
2. **Address dependent.** The NetScaler appliance filters out packets not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x). In addition, the appliance filters out packets from external host IP address and port (Y:y) destined for N:n if the subscriber has not previously sent packets to Y:anyport (external port independent). In other words, receiving

© 1997–2026 Citrix Systems, Inc. All rights reserved.

packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.

3. **Address port dependent.** The NetScaler appliance filters out packets not destined to NAT IP:port (N:n), which represents subscriber IP:port (X:x). In addition, the appliance filters out packets from external host IP address and port (Y:y) destined for N:n if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external IP address and port.

Quotas

The NetScaler appliance can limit the number of NAT ports and sessions for each subscriber to ensure fair distribution of resources among subscribers. The NetScaler appliance can also limit the number of session for a subscriber group to ensure fair distribution of resources among different subscriber groups.

- **Port quota.** The NetScaler appliance can limit the LSN NAT ports to be used at a time by each subscriber for a specified protocol. For example, you could limit each subscriber to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the NetScaler appliance does not allocate additional NAT ports of the specified protocol to that subscriber.
- **Subscriber Session Limit.** The number of concurrent session for a subscriber can be more than it port quota. The NetScaler appliance can limit the LSN sessions allowed for each subscriber for a specified protocol. When the number of LSN sessions reaches the limit for a subscriber, the NetScaler appliance does not allow the subscriber to open additional sessions of the specified protocol.
- **Group Session Limit.** The NetScaler appliance can limit the total number of LSN sessions allowed for a subscriber group for a specified protocol. When the total number of LSN sessions reaches the limit for a group for a specified protocol, the NetScaler appliance does not allow any subscriber of the group to open additional sessions of the specified protocol. For example, You limit a group to a maximum of 10000 UDP sessions. When the total number of UDP sessions for this group reaches 10000, the NetScaler appliance does not allow any subscriber of the group to open additional UDP sessions.

Application Layer Gateways

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway for a protocol parses the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

packet’s payload and does necessary changes to ensure that the protocol continues to work over LSN.

The NetScaler appliance supports ALG for the following protocols:

- FTP
- ICMP
- TFTP
- PPTP
- SIP
- RTSP

Hairpin Support

The NetScaler appliance supports communication between subscribers or internal hosts using NAT IP addresses. This type of communication between two subscribers using NAT IP addresses is called hairpin flow. Hairpin flow is enabled by default, and you cannot disable it.

Points to Consider before Configuring LSN

Consider the following points before configuring LSN on a NetScaler appliance:

- Make sure that you understand the different components of Large Scale NAT, described in RFCs 6888, 5382, 5508, and 4787.
- Endpoint independent mapping (EIM) and endpoint independent filtering (EIF) are disabled by default. These options must be enabled for proper functioning of VoIP and peer-to-peer (P2P) applications.
- **Logging LSN**: Following are the consideration points for logging LSN information:
    - Citrix recommends logging the LSN information on external log servers instead of on the NetScaler appliance. Logging on external servers facilitates optimal performance when the appliance creates large numbers of LSN log entries (in order of millions).
    - Citrix® recomends using SYSLOG over TCP, or NSLOG. By default SYSLOG uses UDP, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.
    - The following limitations apply to SYSLOG over TCP:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - The Syslog over TCP solution does not provide authentication, integrity check, and privacy.
    - The NetScaler appliance relies on the TCP protocol to provide confirmation of SYSLOG message delivery to external log servers.

- **High Availability**: Following are the consideration points for high availability of NetScaler appliances for LSN:
    - Citrix recommends configuring the LSN feature in a high availability deployment of two NetScaler appliances for uninterrupted and seamless operation of all LSN sessions.
    - In a high availability deployment, Citrix recommends:
        - Setting the SYNC VLAN parameter for dedicating a VLAN for all HA related communication.
        - Synchronizing the symmetric RSS key of the primary node to the secondary node for stateful synchronization of a large number of LSN mappings and sessions.
        - Binding the subnet of LSN IP addresses to a VLAN to avoid flooding of GARP broadcasts on all VLANs after a failover.
    - In a high availability deployment of NetScaler appliances, ALG-related sessions are not mirrored to the secondary appliance.
- **Application Layer Gateways (ALGs)**: Following are the consideration points related for ALGs on a NetScaler appliance:
    - The following are not supported for SIP ALG:
        - Multicast IP addresses
        - Encrypted SDP
        - SIP messages over TLS
        - FQDN translation in SIP messages
        - Authentication of SIP messages
        - Traffic domains, admin partitions, andNetScaler clusters.
        - SIP messages with multipart bodies.
    - The following are not supported for RTSP ALG:
        - Multicast RTSP sessions
        - RTSP session over UDP

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - NetScaler traffic domains, admin partitions, andNetScaler clusters
  - The NetScaler appliance does not support ALG for the IPSec protocol.

- If you disable the LSN feature when some LSN sessions exist on the NetScaler appliance, these sessions continue to exist for the duration of the configured timeout interval.
- LSN takes precedence over RNAT. If a packet from a specified LSN subscriber also matches a RNAT rule, the packet is translated according to the LSN configuration.
- Forwarding of packets related only to the LSN sessions is based on the NetScaler appliance's routing table.
- Unlike with subnet IP addresses, selection of an LSN NAT IP address for a subscriber's connection is not based on the routing entry for the destination IP address.
- For inbound packets, static LSN mappings take precedence over dynamic LSN mappings.
- For outbound packets, LSN application profiles take precedence over static mapping.
- When a large number of LSN sessions (\> 1 million) exist on the NetScaler appliance, Citrix recommends displaying selected LSN sessions instead of all of them. In the command line interface or the configuration utility, use the selection parameters for showing LSN session operation.
- To reduce the amount of active memory allocated to the LSN feature, you must warm restart the NetScaler appliance after changing the configured-memory setting. Without a warm restart, you can only increase the amount of active memory.

Configuration Steps for LSN

Configuring LSN on a NetScaler appliance consists of the following tasks:

1. **Set the global LSN parameters.** Global parameters include the amount of NetScaler memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
2. **Create an LSN client entity and bind subscribers to it.** An LSN client entity is a set of subscribers on whose traffic you want the NetScaler appliance to perform LSN. The client entity includes IPv4 addresses and extended ACL rules for identifying subscribers. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The configuration utility combines these two operations on a single screen.
3. **Create an LSN pool and bind NAT IP addresses to it.** An LSN pool defines a pool of NAT IP addresses to be used by the NetScaler appliance to perform LSN. The pool is assigned parameters, such as port block allocation and NAT type (Deterministic or Dynamic). An LSN

© 1997–2026 Citrix Systems, Inc. All rights reserved.

pool bound to an LSN group applies to all subscribers of an LSN client entity bound to the same group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiple LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The configuration utility combines these two operations on a single screen.

4. **(Optional) Create an LSN Transport Profile for a specified protocol.** An LSN transport profile defines various timeouts and limits, such as maximum LSN sessions and maximum ports usage, that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
5. **(Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it.** An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The configuration utility combines these two operations on a single screen.
6. **Create an LSN Group and bind LSN pools, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group.** An LSN group is an entity consisting of an LSN client, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. For Dynamic NAT, an LSN pool can be bound to multiple LSN groups. For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN

© 1997–2026 Citrix Systems, Inc. All rights reserved.

groups. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, LSN application profiles to the LSN group. The configuration utility combines these two operations in a single screen.

The following table lists the maximum numbers of different LSN entities and bindings that can be created on a NetScaler appliance. These limits are also subject to memory available on the NetScaler appliance.

LSN ENTITIES AND BINDINGS	LIMIT
LSN clients	1024
LSN pools	128
LSN groups	1024
Subscriber networks that can be bound to an LSN client	64
Extended ACLs that can be bound to an LSN client	1024
NAT IP addresses in a Pool	4096
LSN pools that can be bound to an LSN group	8
LSN groups that can use the same LSN pool	16
LSN transport profiles that can be bound to an LSN group	3 (one each for TCP, UDP, and ICMP protocols)
LSN groups that can use same LSN transport profile	8
LSN application profiles that can be bound to an LSN group	64
LSN groups that can use same LSN application profile	8

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LSN ENTITIES AND BINDINGS	LIMIT
Port ranges that can be bound to an LSN application profile	8

Configuration Using the Command Line Interface

To create an LSN client by using the command line interface

At the command prompt, type:

```
add lsn client <clientname>

show lsn client
```

To bind a network address or an ACL rule to an LSN client by using the command line interface

At the command prompt, type:

```
bind lsn client <clientname> ((-network <ip_addr> [-netmask <netmask>] [-
td<positive_integer>]) | -aclname <string>)

show lsn client
```

To create an LSN pool by using the command line interface

At the command prompt, type:

```
add lsn pool <poolname> [-nattype ( DYNAMIC | DETERMINISTIC )] [-
portblockallocation ( ENABLED | DISABLED )] [-portrealloctimeout <secs>]
[-maxPortReallocTmq <positive_integer>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn pool
```

To bind an IP address range to an LSN pool by using the command line interface

At the command prompt, type:

```
bind lsn pool <poolname> <lsnip>

show lsn pool
```

Note: For removing LSN IP addresses from an LSN pool, use the unbind lsn pool command.

To create an LSN transport profile by using the command line interface

At the command prompt, type:

```
add lsn transportprofile <transportprofilename> <transportprotocol> [-
sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota
<positive_integer>] [-sessionquota <positive_integer>] [-
portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (ENABLED |
DISABLED )] [-syncheck ( ENABLED | DISABLED )]

show lsn transportprofile
```

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling
(PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
tcpproxy ( ENABLED | DISABLED )] [-td <positive_integer>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn appsprofile
```

To bind an application protocol port range to an LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
```

To create an LSN group by using the command line interface

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC |
DETERMINISTIC )] [-portblocksize <positive_integer>] [-logging (ENABLED |
DISABLED )] [-sessionLogging ( ENABLED | DISABLED )][-sessionSync (ENABLED
| DISABLED )] [-snmptraplimit <positive_integer>] [-ftp ( ENABLED |
DISABLED )]

show lsn group
```

To bind LSN profiles and LSN pools to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
<string> | -appsprofilename <string>)

show lsn group
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration Using the Configuration Utility

To configure an LSN client and bind an IPv4 network address or an ACL rule by using the configuration utility

Navigate to **System** > **Large Scale NAT** > **Clients**, and add a client and then bind an IPv4 network address or an ACL rule to the client.

To configure an LSN pool and bind NAT IP addresses by using the configuration utility

Navigate to **System > Large Scale NAT** > **Pools**, and add a pool and then bind an NAT IP address or a range of NAT IP addresses to the pool.

To configure an LSN transport profile by using the configuration utility

1. Navigate to **System > Large Scale NAT > Profiles**.
2. On the details pane, click **Transport** tab, and then add a transport profile.

To configure an LSN application profile by using the configuration utility

1. Navigate to **System > Large Scale NAT > Profiles**.
2. On the details pane, click **Application** tab, and then add an application profile.

To configure an LSN group and bind an LSN client, pools, transport profiles, and application profiles by using the configuration utility

Navigate to **System > Large Scale NAT > Groups**, and add a group and then bind an LSN client, pools, transport profiles, and application profiles to the group.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn client
  - clientname

    Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn client1" or 'lsn client1').

    This is a mandatory argument. Maximum Length: 127

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn client
  - clientname

    Name for the LSN client entity. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN client is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn client1" or 'lsn client1').

    This is a mandatory argument. Maximum Length: 127
  - network

    IPv4 address(es) of the LSN subscriber(s) or subscriber network(s) on whose traffic you want the NetScaler appliance to perform Large Scale NAT.
  - netmask

    Subnet mask for the IPv4 address specified in the Network parameter.

    Default value: 255.255.255.255
  - td

    ID of the traffic domain on which this subscriber or the subscriber network (as specified by the network parameter) belongs.

    If you do not specify an ID, the subscriber or the subscriber network becomes part of the default traffic domain.

    Default value: 0

    Minimum value: 0

    Maximum value: 4094
  - aclname

    Name(s) of any configured extended ACL(s) whose action is ALLOW. The condition specified in the extended ACL rule identifies the traffic from an LSN subscriber for which the NetScaler appliance is to perform large scale NAT. Maximum Length: 127

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn pool
  - poolname

    Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn pool1" or 'lsn pool1').

    This is a mandatory argument. Maximum Length: 127
  - nattype

    Type of NAT IP address and port allocation (from the LSN pools bound to an LSN group) for subscribers (of the LSN client entity bound to the LSN group):

    Available options function as follows:

    - **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The NetScaler appliance sequentially allocates NAT resources to these subscribers. The NetScaler appliance assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.
    - **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscribers connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the NetScaler appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The appliance allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber. Only LSN Pools and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group.

Possible values: DYNAMIC, DETERMINISTIC

Default value: DYNAMIC

- portblockallocation

  Allocate a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber when the NAT allocation is set as Dynamic NAT. For any connection initiated from a subscriber, the NetScaler appliance allocates a NAT port from the subscribers allocated NAT port block to create the LSN session.

  You must set the port block size in the bound LSN group. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the NetScaler appliance allocates a new random port block for the subscriber.

  For Deterministic NAT, this parameter is enabled by default, and you cannot disable it.

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

- portrealloctimeout

  The waiting time, in seconds, between deallocating LSN NAT ports (when an LSN mapping is removed) and reallocating them for a new LSN session. This parameter is necessary in order to prevent collisions between old and new mappings and sessions. It ensures that all established sessions are broken instead of redirected to a different subscriber. This is not applicable for ports used in:

  - Deterministic NAT
  - Address-Dependent filtering and Address-Port-Dependent filtering
  - Dynamic NAT with port block allocation

  In these cases, ports are immediately reallocated.

  Default value: 0

  Maximum value: 600

- maxPortReallocTmq

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Maximum number of ports for which the port reallocation timeout applies for each NAT IP address. In other words, the maximum deallocated-port queue size for which the reallocation timeout applies for each NAT IP address.

When the queue size is full, the next port deallocated is reallocated immediately for a new LSN session.

Default value: 65536

Maximum value: 65536

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn pool
  - poolname

    Name for the LSN pool. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN pool is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn pool1" or 'lsn pool1').

    This is a mandatory argument. Maximum Length: 127
  - lsnip

    IPv4 address or a range of IPv4 addresses to be used as NAT IP address(es) for LSN.

    After the pool is created, these IPv4 addresses are added to the NetScaler appliance as NetScaler owned IP address of type LSN. An LSN IP address associated with an LSN pool cannot be shared with other LSN pools. IP addresses specified for this parameter must not already exist on the NetScaler appliance as any NetScaler owned IP addresses. In the command line interface, separate the range with a hyphen. For example: 10.102.29.30-10.102.29.189. You can later remove some or all the LSN IP addresses from the pool, and add IP addresses to the LSN pool.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn transportprofile
  - transportprofilename

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Name for the LSN transport profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN transport profile is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn transport profile1" or 'lsn transport profile1').

This is a mandatory argument. Maximum Length: 127

- transportprotocol

  Protocol for which to set the LSN transport profile parameters.

  This is a mandatory argument.

  Possible values: TCP, UDP, ICMP

- sessiontimeout

  Timeout, in seconds, for an idle LSN session. If an LSN session is idle for a time that exceeds this value, the NetScaler appliance removes the session.

  This timeout does not apply for a TCP LSN session when a FIN or RST message is received from either of the endpoints.

  Default value: 120

  Minimum value: 60

- finrsttimeout

  Timeout, in seconds, for a TCP LSN session after a FIN or RST message is received from one of the endpoints.

  f a TCP LSN session is idle (after the NetScaler appliance receives a FIN or RST message) for a time that exceeds this value, the NetScaler appliance removes the session.

  Since the LSN feature of the NetScaler appliance does not maintain state information of any TCP LSN sessions, this timeout accommodates the transmission of the FIN or RST, and ACK messages from the other endpoint so that both endpoints can properly close the connection.

  Default value: 30

- portquota

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Maximum number of LSN NAT ports to be used at a time by each subscriber for the specified protocol. For example, each subscriber can be limited to a maximum of 500 TCP NAT ports. When the LSN NAT mappings for a subscriber reach the limit, the NetScaler appliance does not allocate additional NAT ports for that subscriber.

Default value: 0

Minimum value: 0

Maximum value: 65535

- sessionquota

Maximum number of concurrent LSN sessions allowed for each subscriber for the specified protocol. When the number of LSN sessions reaches the limit for a subscriber, the NetScaler appliance does not allow the subscriber to open additional sessions.

Default value: 0

Minimum value: 0

Maximum value: 65535

- portpreserveparity

Enable port parity between a subscriber port and its mapped LSN NAT port. For example, if a subscriber initiates a connection from an odd numbered port, the NetScaler appliance allocates an odd numbered LSN NAT port for this connection. You must set this parameter for proper functioning of protocols that require the source port to be even or odd numbered, for example, in peer-to-peer applications that use RTP or RTCP protocol.

Possible values: ENABLED, DISABLED

Default value: DISABLED

- portpreserverange

If a subscriber initiates a connection from a well-known port (0-1023), allocate a NAT port from the well-known port range (0-1023) for this connection. For example, if a subscriber initiates a connection from port 80, the NetScaler appliance can allocate port 100 as the NAT port for this connection.

This parameter applies to dynamic NAT without port block allocation. It also applies to Deterministic NAT if the range of ports allocated includes well-known ports.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

When all the well-known ports of all the available NAT IP addresses are used in different subscribers connections (LSN sessions), and a subscriber initiates a connection from a well- known port, the NetScaler appliance drops this connection.

Possible values: ENABLED, DISABLED

Default value: DISABLED

- syncheck

Silently drop any non-SYN packets for connections for which there is no LSN-NAT session present on the NetScaler appliance.

If you disable this parameter, the NetScaler appliance accepts any non-SYN packets and creates a new LSN session entry for this connection.

Following are some reasons for the NetScaler appliance to receive such packets:

- LSN session for a connection existed but the NetScaler appliance removed this session because the LSN session was idle for a time that exceeded the configured session timeout.
- Such packets can be a part of a DoS attack.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn appsprofile
  - appsprofilename

    Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn application profile1" or 'lsn application profile1').

    This is a mandatory argument. Maximum Length: 127
  - transportprotocol

    Name of the protocol for which the parameters of this LSN application profile applies.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This is a mandatory argument.

Possible values: TCP, UDP, ICMP

- ippooling

  NAT IP address allocation options for sessions associated with the same subscriber.

  Available options function as follows:

  - **Paired**—The NetScaler appliance allocates the same NAT IP address for all sessions associated with the same subscriber. When all the ports of a NAT IP address are used in LSN sessions (for same or multiple subscribers), the NetScaler appliance drops any new connection from the subscriber.
  - **Random**—The NetScaler appliance allocates random NAT IP addresses, from the pool, for different sessions associated with the same subscriber.

  This parameter is applicable to dynamic NAT allocation only.

  Possible values: PAIRED, RANDOM

  Default value: RANDOM

- mapping

  Type of LSN mapping to apply to subsequent packets originating from the same subscriber IP address and port.

  Consider an example of an LSN mapping that includes the mapping of the subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

  Available options function as follows:

  - **ENDPOINT-INDEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to any external IP address and port.
  - **ADDRESS-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same subscriber IP address and port (X:x) to the same external IP address (Y), regardless of the external port.
  - **ADDRESS-PORT-DEPENDENT**—Reuse the LSN mapping for subsequent packets sent from the same internal IP address and port (X:x) to the same external IP address and port (Y:y) while the mapping is still active.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

Default value: ADDRESS-PORT-DEPENDENT

- filtering

  Type of filter to apply to packets originating from external hosts.

  Consider an example of an LSN mapping that includes the mapping of subscriber IP:port (X:x), NAT IP:port (N:n), and external host IP:port (Y:y).

  Available options function as follows:

  - **ENDPOINT INDEPENDENT**—Filters out only packets not destined to the subscriber IP address and port X:x, regardless of the external host IP address and port source (Z:z). The NetScaler appliance forwards any packets destined to X:x. In other words, sending packets from the subscriber to any external IP address is sufficient to allow packets from any external hosts to the subscriber.
  - **ADDRESS DEPENDENT**—Filters out packets not destined to subscriber IP address and port X:x. In addition, the appliance filters out packets from Y:y destined for the subscriber (X:x) if the client has not previously sent packets to Y:anyport (external port independent). In other words, receiving packets from a specific external host requires that the subscriber first send packets to that specific external host's IP address.
  - **ADDRESS PORT DEPENDENT** (the default)—Filters out packets not destined to subscriber IP address and port (X:x). In addition, the NetScaler appliance filters out packets from Y:y destined for the subscriber (X:x) if the subscriber has not previously sent packets to Y:y. In other words, receiving packets from a specific external host requires that the subscriber first send packets first to that external IP address and port.

  Possible values: ENDPOINT-INDEPENDENT, ADDRESS-DEPENDENT, ADDRESS-PORT-DEPENDENT

  Default value: ADDRESS-PORT-DEPENDENT

- tcpproxy

  Enable TCP proxy, which enables the NetScaler appliance to optimize the TCP traffic by using Layer 4 features.

  Possible values: ENABLED, DISABLED

  Default value: DISABLED

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- td

  ID of the traffic domain through which the NetScaler appliance sends the outbound traffic after performing LSN.

  If you do not specify an ID, the appliance sends the outbound traffic through the default traffic domain, which has an ID of 0.

  Default value: 65535

  Maximum value: 65535

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn appsprofile
  - appsprofilename

    Name for the LSN application profile. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN application profile is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn application profile1" or 'lsn application profile1').

    This is a mandatory argument. Maximum Length: 127
  - lsnport

    Port numbers or range of port numbers to match against the destination port of the incoming packet from a subscriber. When the destination port is matched, the LSN application profile is applied for the LSN session. Separate a range of ports with a hyphen. For example, 40-90.

Parameter Descriptions (of commands listed in the CLI procedure)

- add lsn group
  - groupname

    Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name

© 1997–2026 Citrix Systems, Inc. All rights reserved.

includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn group1" or 'lsn group1').

This is a mandatory argument. Maximum Length: 127

- clientname

  Name of the LSN client entity to be associated with the LSN group. You can associate only one LSN client entity with an LSN group. You cannot remove this association or replace with another LSN client entity once the LSN group is created.

  This is a mandatory argument. Maximum Length: 127

- nattype

  Type of NAT IP address and port allocation (from the bound LSN pools) for subscribers:

  Available options function as follows:

  - **Deterministic**—Allocate a NAT IP address and a block of ports to each subscriber (of the LSN client bound to the LSN group). The NetScaler appliance sequentially allocates NAT resources to these subscribers. The NetScaler appliance assigns the first block of ports (block size determined by the port block size parameter of the LSN group) on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. In this case, the first port block on the next NAT address is used for the subscriber, and so on. Because each subscriber now receives a deterministic NAT IP address and a block of ports, a subscriber can be identified without any need for logging. For a connection, a subscriber can be identified based only on the NAT IP address and port, and the destination IP address and port.
  - **Dynamic**—Allocate a random NAT IP address and a port from the LSN NAT pool for a subscriber's connection. If port block allocation is enabled (in LSN pool) and a port block size is specified (in the LSN group), the NetScaler appliance allocates a random NAT IP address and a block of ports for a subscriber when it initiates a connection for the first time. The appliance allocates this NAT IP address and a port (from the allocated block of ports) for different connections from this subscriber. If all the ports are allocated (for different subscribers connections) from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber.

  Possible values: DYNAMIC, DETERMINISTIC

  Default value: DYNAMIC

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- portblocksize

  Size of the NAT port block to be allocated for each subscriber.

  To set this parameter for Dynamic NAT, you must enable the port block allocation parameter in the bound LSN pool. For Deterministic NAT, the port block allocation parameter is always enabled, and you cannot disable it.

  In Dynamic NAT, the NetScaler appliance allocates a random NAT port block, from the available NAT port pool of an NAT IP address, for each subscriber. For a subscriber, if all the ports are allocated from the subscribers allocated port block, the appliance allocates a new random port block for the subscriber.

- logging

  Log mapping entries and sessions created or deleted for this LSN group. The NetScaler appliance logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

  The appliance uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYLOG action entities. When the Logging parameter is enabled, the NetScaler appliance generates log messages related to LSN mappings and LSN sessions of this LSN group. The appliance then sends these log messages to servers associated with the NSLOG action and SYSLOG actions entities.

  A log message for an LSN mapping entry consists of the following information:

  - NSIP address of the NetScaler appliance
  - Time stamp
  - Entry type (MAPPING or SESSION)
  - Whether the LSN mapping entry is created or deleted
  - Subscriber's IP address, port, and traffic domain ID
  - NAT IP address and port
  - Protocol name
  - Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:

    - Destination IP address and port are not logged for Endpoint-Independent mapping

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Only Destination IP address (and not port) is logged for Address-Dependent mapping
- Destination IP address and port are logged for Address-Port-Dependent mapping

Possible values: ENABLED, DISABLED

Default value: DISABLED

- sessionLogging

Log sessions created or deleted for the LSN group. The NetScaler appliance logs LSN sessions for this LSN group only when both logging and session logging parameters are enabled.

A log message for an LSN session consists of the following information:

- NSIP address of the NetScaler appliance
- Time stamp
- Entry type (MAPPING or SESSION)
- Whether the LSN session is created or removed
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

Possible values: ENABLED, DISABLED

Default value: DISABLED

- sessionSync

In a high availability (HA) deployment, synchronize information of all LSN sessions related to this LSN group with the secondary node. After a failover, established TCP connections and UDP packet flows are kept active and resumed on the secondary node (new primary).

For this setting to work, you must enable the global session synchronization parameter.

Possible values: ENABLED, DISABLED

Default value: ENABLED

- snmptraplimit

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Maximum number of SNMP Trap messages that can be generated for the LSN group in one minute.

Default value: 100

Minimum value: 0

Maximum value: 10000

- ftp

Enable Application Layer Gateway (ALG) for the FTP protocol. For some application-layer protocols, the IP addresses and protocol port numbers are usually communicated in the packets payload. When acting as an ALG, the appliance changes the packets payload to ensure that the protocol continues to work over LSN.

Note: The NetScaler appliance also includes ALG for ICMP and TFTP protocols. ALG for the ICMP protocol is enabled by default, and there is no provision to disable it. ALG for the TFTP protocol is disabled by default. ALG is enabled automatically for an LSN group when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Possible values: ENABLED, DISABLED

Default value: ENABLED

Parameter Descriptions (of commands listed in the CLI procedure)

- bind lsn group
  - groupname

    Name for the LSN group. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn group1" or 'lsn group1').

    This is a mandatory argument. Maximum Length: 127
  - poolname

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Name of the LSN pool to bind to the specified LSN group. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group.

For Deterministic NAT, pools bound to an LSN group cannot be bound to other LSN groups. For Dynamic NAT, pools bound to an LSN group can be bound to multiple LSN groups. Maximum Length: 127

- transportprofilename

Name of the LSN transport profile to bind to the specified LSN group. Bind a profile for each protocol for which you want to specify settings.

By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called a default transport.

An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol. Maximum Length: 127

- appsprofilename

Name of the LSN application profile to bind to the specified LSN group. For each set of destination ports, bind a profile for each protocol for which you want to specify settings.

By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile.

When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. Maximum Length: 127

Sample LSN Configurations

The following are examples of configuring LSN through command line interface.

Create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, and default settings:

```
add lsn client LSN-CLIENT-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create an LSN configuration with an extended ACL for identifying LSN subscribers:

```
add ns acl LSN-ACL-2 ALLOW -srcIP 192.0.2.10-192.0.2.20

Done

apply acls

Done

add lsn client LSN-CLIENT-2

Done

bind lsn client LSN-CLIENT-2 –aclname LSN-ACL-2

Done

add lsn pool LSN-POOL-2

Done

bind lsn pool LSN-POOL-2 203.0.113.5-203.0.113.10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn group LSN-GROUP-2 -clientname LSN-CLIENT-2

Done

bind lsn group LSN-GROUP-2 -poolname LSN-POOL-2

Done
```

Create an LSN configuration with endpoint-independent mapping for HTTP protocol (port 80) and address-port dependent mapping for SSH protocol (port 22). Also, restrict each subscriber to use a maximum of 1000 NAT ports for TCP protocol and 100 NAT ports for UDP protocol. Restrict each subscriber to have a maximum of 2000 concurrent sessions for TCP protocol. Restrict the group to have a maximum of 30000 concurrent sessions for TCP protocol:

```
add lsn client LSN-CLIENT-3

Done

bind lsn client LSN-CLIENT-3 -network 192.0.3.0 -netmask 255.255.255.0

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn pool LSN-POOL-3

Done

bind lsn pool LSN-POOL-3 203.0.113.11

Done

add lsn group LSN-GROUP-3 -clientname LSN-CLIENT-3

Done

bind lsn group LSN-GROUP-3 -poolname LSN-POOL-3

Done

add lsn appsprofile LSN-APPS-HTTPPROFILE-3 TCP -mapping ENDPOINT-
INDEPENDENT

Done

bind lsn appsprofile LSN-APPS-HTTPPROFILE-3 80
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group LSN-GROUP-3 -applicationprofilename LSN-APPS-HTTPPROFILE-3

Done

add lsn appsprofile LSN-APPS-SSHPROFILE-3 TCP -mapping ADDRESS-PORT-
DEPENDENT

Done

bind lsn appsprofile LSN-APPS-SSHPROFILE-3 22

Done

bind lsn group LSN-GROUP-3 -applicationprofilename LSN-APPS-SSHPROFILE-3

Done

add lsn transportprofile LSN-TRANS-PROFILE-TCP-3 TCP -portquota 1000
-sessionquota 2000 -groupSessionLimit 30000
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group LSN-GROUP-3 -transportprofilename LSN-TRANS-PROFILE-TCP-3

Done

add lsn transportprofile LSN-TRANS-PROFILE-UDP-3 UDP -portquota 100

Done

bind lsn group LSN-GROUP-3 -transportprofilename LSN-TRANS-PROFILE-UDP-3

Done
```

Create an LSN configuration for a large set of subscribers:

```
add lsn client LSN-CLIENT-4

Done

bind lsn client LSN-CLIENT-4 -network 192.0.4.0 -netmask 255.255.255.0

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn client LSN-CLIENT-4 -network 192.0.5.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.6.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.7.0 -netmask 255.255.255.0

Done

bind lsn client LSN-CLIENT-4 -network 192.0.8.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-4

Done

bind lsn pool LSN-POOL-4 203.0.113.30-203.0.113.40
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn pool LSN-POOL-4 203.0.113.45-203.0.113.50

Done

bind lsn pool LSN-POOL-4 203.0.113.55-203.0.113.60

Done

add lsn group LSN-GROUP-4 -clientname LSN-CLIENT-4

Done

bind lsn group LSN-GROUP-4 -poolname LSN-POOL-4

Done

add lsn appsprofile LSN-APPS-WELLKNOWNPROFILE-4 TCP -mapping ENDPOINT-
INDEPENDENT

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn appsprofile LSN-APPS-WELLKNOWN-PORTS-PROFILE-4 1- 1023

Done

bind lsn group LSN-GROUP-4 -applicationprofilename LSN-APPS-WELLKNOWN-
PORTS-PROFILE-4

Done
```

Create an LSN configuration with sharing of NAT resources among multiple LSN groups. In this example, LSN pool LSN-POOL-5 is shared with LSN groups LSN-GROUP-5 and LSN-GROUP-6:

```
add lsn client LSN-CLIENT-5

Done

bind lsn client LSN-CLIENT-5 -network 192.0.15.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-5

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn pool LSN-POOL-5 203.0.113.12-203.0.113.14

Done

add lsn group LSN-GROUP-5 -clientname LSN-CLIENT-5

Done

bind lsn group LSN-GROUP-5 -poolname LSN-POOL-5

Done

add lsn client LSN-CLIENT-6

Done

bind lsn client LSN-CLIENT-6 -network 192.0.16.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-6
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn pool LSN-POOL-6 203.0.113.15-203.0.113.18

Done

add lsn group LSN-GROUP-6 -clientname LSN-CLIENT-6

Done

bind lsn group LSN-GROUP-6 -poolname LSN-POOL-6

Done

bind lsn group LSN-GROUP-6 -poolname LSN-POOL-5

Done
```

Create an LSN configuration with deterministic NAT resource allocation:

```
add lsn client LSN-CLIENT-7
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn client LSN-CLIENT-7 -network 192.0.17.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-7 -nattype DETERMINISTIC

Done

bind lsn pool LSN-POOL-7 203.0.113.19-203.0.113.23

Done

add lsn group LSN-GROUP-7 -clientname LSN-CLIENT-7 -nattype DETERMINISTIC
-portblocksize 1024

Done

bind lsn group LSN-GROUP-7 -poolname LSN-POOL-7
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Create an LSN configuration with multiple subscriber networks having the same network address but each network belonging to a different traffic domain. Also, restrict the outbound traffic related to HTTP protocol (port 80), sending it through a particular traffic domain (td 5):

```
add lsn client LSN-CLIENT-8

Done

bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
-td 1

Done

bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
-td 2

Done

bind lsn client LSN-CLIENT-8 -network 192.0.18.0 -netmask 255.255.255.0
-td 3

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn pool LSN-POOL-8

Done

bind lsn pool LSN-POOL-8 203.0.113.80-203.0.113.86

Done

add lsn group LSN-GROUP-8 -clientname LSN-CLIENT-8

Done

bind lsn group LSN-GROUP-8 -poolname LSN-POOL-8

Done

add lsn appsprofile LSN-APPS-HTTP-PROFILE-8 TCP -td 5

Done

bind lsn appsprofile LSN-APPS-HTTP-PROFILE-8 80
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group LSN-GROUP-8 -applicationprofilename LSN-APPS-HTTP-PROFILE-8

Done
```

Create an LSN configuration that restricts the outbound traffic of a specific protocol (TCP), sending it through a particular traffic domain (td 5). With endpoint-independent filtering, receive inbound traffic related to this protocol (TCP) on any traffic domain:

```
add lsn client LSN-CLIENT-9

Done

bind lsn client LSN-CLIENT-9 -network 192.0.9.0 -netmask 255.255.255.0 -td
1

Done

add lsn pool LSN-POOL-9

Done

bind lsn pool LSN-POOL-9 203.0.113.90
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9

Done

bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9

Done

add lsn appsprofile LSN-APPS-PROFILE-9 TCP -filtering ENDPOINT-INDEPENDENT
-td 5

Done

bind lsn group LSN-GROUP-9 -approfile LSN-APPS-PROFILE-9

Done
```

Create an LSN configuration that restricts outbound HTTP (port 80) traffic, sending it through a particular traffic domain (td 10). With address-dependent filtering, receive inbound traffic related to this protocol (HTTP) on the specified traffic domain (td 10):

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn client LSN-CLIENT-10

Done

bind lsn client LSN-CLIENT-10 -network 192.0.10.0 -netmask 255.255.255.0
-td 1

Done

add lsn pool LSN-POOL-10

Done

bind lsn pool LSN-POOL-10 203.0.113.100

Done

add lsn group LSN-GROUP-10 -clientname LSN-CLIENT-10

Done

bind lsn group LSN-GROUP-10 -poolname LSN-POOL-10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn appsprofile LSN-APPS-PROFILE-10 TCP -mapping ENDPOINT -INDEPENDENT
-filtering ADDRESS-DEPENDENT -td 10

Done

bind lsn appsprofile LSN-APPS-PROFILE-10 80

Done

bind lsn group LSN-GROUP-10 -approfile LSN-APPS-PROFILE-10

Done
```

Configuring Static LSN Maps

The NetScaler appliance supports manual creation of a one-to-one LSN mapping between a subscriber IP address:port and a NAT IP address:port. Static LSN mappings are useful in cases where you want to ensure that the connections initiated to a NAT IP:Port maps to the subscriber IP address:Port. For example, Web servers located in the internal network.

To create a static LSN mapping by using the command line interface

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn static <name> <transportprotocol> <subscrIP> <subscrPort> [-td
<positive_integer>] [<natIP> [<natPort>]] [-destIP <ip_addr> [-dsttd
<positive_integer>]]

-  show lsn static
```

To create a static LSN mapping by using the configuration utility

Navigate to System > Large Scale NAT > Static, and add a new static mapping.

Parameter Descriptions (of commands listed in the CLI procedure)

add lsn static name

Name for the LSN static mapping entry. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "lsn static1" or 'lsn static1'). This is a mandatory argument. Maximum Length: 127

transportprotocol

Protocol for the LSN mapping entry. This is a mandatory argument. Possible values: TCP, UDP, ICMP

subscrIP

IPv4 address of an LSN subscriber for the LSN mapping entry. This is a mandatory argument.

subscrPort

Port of the LSN subscriber for the LSN mapping entry. This is a mandatory argument. Maximum value: 65535

td

ID of the traffic domain to which the subscriber belongs. If you do not specify an ID, the subscriber is assumed to be a part of the default traffic domain. Default value: 0, Minimum value: 0, Maximum value: 4094

© 1997–2026 Citrix Systems, Inc. All rights reserved.

natIP

IPv4 address, already existing on the NetScaler appliance as type LSN, to be used as NAT IP address for this mapping entry.

natPort

NAT port for this LSN mapping entry.

destIP

Destination IP address for the LSN mapping entry.

dsttd

ID of the traffic domain through which the destination IP address for this LSN mapping entry is reachable from the NetScaler appliance. If you do not specify an ID, the destination IP address is assumed to be reachable through the default traffic domain, which has an ID of 0. Default value: 0, Minimum value: 0, Maximum value: 4094

Wildcard Port Static Maps

A static mapping entry is usually a one-to-one LSN mapping between a subscriber IP address:port and a NAT IP address:port. A one-to-one static LSN mapping entry exposes only one port of the subscriber to the Internet.

Some situations might require exposing all ports (64K) of a subscriber to the Internet (for example, a server hosted on an internal network and running a different service on each port). To make these internal services accessible through the Internet, you have to expose all the ports of the server to the Internet.

One way to meet this requirement is to add 64K one-to-one static mapping entries, one mapping entry for each port. Creating 64K entries is very cumbersome and a big task. Also, this large number of configuration entries might lead to performance issues in the NetScaler appliance.

Another simple method is to use wildcard ports in a static mapping entry. You just need to create one static mapping entry with NAT-port and subscriber-port parameters set to the wildcard character (*), and the protocol parameter set to ALL, to expose all the ports of a subscriber to the Internet. For a subscriber’s inbound or outbound connections matching a wildcard static mapping entry, the subscriber’s port does not change after the NAT operation.

When a subscriber-initiated connection to the Internet matches a wildcard static mapping entry, the NetScaler appliance assigns a NAT port that has the same number as the subscriber port from

© 1997–2026 Citrix Systems, Inc. All rights reserved.

which the connection is initiated. Similarly, an Internet host gets connected to a subscriber's port by connecting to the NAT port that has the same number as the subscriber's port.

Configuring the NetScaler appliance to Provide Access to All Ports of an IPv4 Subscriber

To configure the NetScaler appliance to provide access to all ports of an IPv4 subscriber, create a wildcard static map with the following mandatory parameter settings:

- Protocol=ALL
- Subscriber port = *
- NAT port = *

In a wildcard static map, unlike in a one-to-one static map, setting the NAT IP parameter is mandatory. Also, the NAT IP address assigned to a wildcard static map cannot be used for any other subscribers.

To create a wildcard static map by using the command line interface

At the command prompt, type:

```
add lsn static <name> ALL <subscrIP> *  <natIP> * [-td <positive_integer>]
[-destIP <ip_addr> [-dsttd <positive_integer>]]

show lsn static
```

Sample Configuration

In the following sample configuration of a wildcard static map, all ports of a subscriber whose IP address is 192.0.2.10 are made accessible through NAT IP 203.0.11.33.

Sample configuration:

```
add lsn static NAT44-WILDCARD-STATIC-1 ALL  192.0.2.10 * 203.0.113.33 *

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring Application Layer Gateways

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway for a protocol parses the packet’s payload and does necessary changes to ensure that the protocol continues to work over LSN.

The NetScaler appliance supports ALG for the following protocols:

- FTP
- ICMP
- TFTP
- PPTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

You can enable or disable ALG for the FTP protocol for an LSN configuration by enabling or disabling the FTP option of the LSN group of the LSN configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for an LSN configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Sample LSN Configuration for FTP ALG: In the following sample LSN configuration, FTP ALG is enabled for subscribers that have IP address in the range 192.0.2.30-192.0.2.100.

```
add ns acl LSN-ACL-1 ALLOW -srcIP 192.0.2.30-192.0.2.100

Done

apply acls
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 –aclname LSN-ACL

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.10

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1  -FTP ENABLED

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done
```

Sample LSN Configuration for TFTP ALG:

In the following sample LSN configuration, endpoint-independent mapping and endpoint-independent filtering are enabled for TFTP protocol (UDP port 69). The NetScaler appliance automatically enables TFTP ALG for this LSN configuration.

```
add lsn client LSN-CLIENT-2

Done

bind lsn client LSN-CLIENT-2 -network 198.51.100.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-2

Done

bind lsn pool LSN-POOL-2 203.0.113.10-203.0.113.11

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn group LSN-GROUP-2 -clientname LSN-CLIENT-2

Done

bind lsn group LSN-GROUP-2 -poolname pool1 LSN-POOL-2

Done

add lsn appsprofile LSNAPPSPROFILE-TFTP-2 UDP -mapping ENDPOINT-
INDEPENDENT –filtering  ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile LSNAPPSPROFILE-TFTP-2 69

Done

bind lsn group LSN-GROUP-1 -applicationprofilename LSNAPPSPROFILE-TFTP-2

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Application Layer Gateway for PPTP Protocol

The NetScaler appliance supports Application Layer Gateways (ALGs) for the Point-to-Point Tunneling Protocol (PPTP).

PPTP is a network protocol that enables secure transfer of data from a remote client to an enterprise server by creating a tunnel across TCP/IP-based data networks. PPTP encapsulates PPP packets into IP packets for transmission over the Internet. PPTP establishes a tunnel for each communicating PPTP network server (PNS)-PPTP Access Concentrator (PAC) pair. After the tunnel is set up, enhanced generic routing encapsulation (GRE) is used to exchange PPP packets. A call ID in the GRE header indicates the session to which a particular PPP packet belongs.

The NetScaler appliance recognizes PPTP packets that arrive on the default TCP port, 1723. The appliance parses PPTP control packets, translates the call ID, and assigns a NAT IP address. For two-way data communication between the client and server, the NetScaler appliance creates an LSN session entry based on the server call ID, and an LSN session based on the client call ID. The appliance then parses the GRE data packets and translates call IDs on the basis of the two LSN session entries.

For PPTP protocol, the NetScaler appliance also includes timeout setting for any idle PPTP LSN sessions. If a PPTP LSN session is idle for a time that exceeds the timeout setting, the NetScaler appliance removes the session.

Limitations:

The following are the limitations of PPTP ALG on a NetScaler appliance:

- PPTP ALG is not supported for hairpin LSN flow.
- PPTP ALG is not supported to work with any RNAT configuration.
- PPTP ALG is not supported in NetScaler clusters.

Configuring PPTP ALG

Configuring PPTP ALG on the NetScaler appliance consist of the following tasks:

- Create an LSN configuration and enable PPTP ALG on it. In an LSN configuration, the LSN group includes the PPTP ALG setting. For instructions on creating an LSN configuration, see Configuration Steps for LSN.
- (Optional) Set the global timeout for idle PPTP LSN sessions.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable PPTP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-pptp ( ENABLED |
DISABLED )]

show lsn group
```

To set the global timeout for idle PPTP LSN sessions by using the CLI

At the command prompt, type:

```
set appAlgParam -pptpGreIdleTimeout <positive_integer>

show appAlgParam
```

Example:

In the following sample LSN configuration, PPTP ALG is enabled for subscribers in the 192.0.2.0/24 network.

Also idle PPTP LSN session timeout is set to 200 secs.

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1  -pptp ENABLED

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done

set appAlgParam -pptpGreIdleTimeout 200

Done
```

Application Layer Gateway for SIP Protocol

Using Large Scale NAT (LSN) with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used

© 1997–2026 Citrix Systems, Inc. All rights reserved.

with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media.

SIP ALG adheres to the following RFCs:

- RFC 3261
- RFC 3581
- RFC 4566
- RFC 4475

NOTE

SIP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

How SIP ALG Works

How IP address translation is performed depends on the type and direction of the message. A message can be any of the following:

- Inbound request
- Outbound response
- Outbound request
- Inbound response

For an outgoing message, the private IP address and port number of the SIP client are replaced with the NetScaler owned public IP address and port number, called the *LSN pool IP address and port number*, specified during LSN configuration. For an incoming message, the LSN pool IP address and the port number are replaced with the private address of the client. If the message contains any public IP addresses, the NetScaler SIP ALG retains them. Also, a pinhole is created on the:

- LSN pool IP address and port on behalf of the private client, so that the messages that arrive at this IP address and port from the public network are treated as SIP messages.
- Public IP address and port on behalf of the public clients, so that the messages that arrive at this IP address and port from the private network are treated as SIP messages.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

When a SIP message is sent out across the network, the SIP Application Layer Gateway (ALG) collects information from the message and translates the IP addresses in the following headers into LSN pool IP addresses:

- Via
- Contact
- Route
- Record-Route

In the following sample SIP request message, LSN replaces the IP addresses in the header fields to hide them from the outside network.

```
INVITE adam@10.102.185.156 SIP/2.0 Via: SIP/2.0/UDP 192.170.1.161:62914
From: eve@10.120.210.3 To: adam@10.102.185.156 Call-ID:
a12abcde@10.120.210.3 Contact: adam@10.102.185.156 Route:
<sip:netscreen@10.150.20.3:5060> Record-Route:
<sip:netscreen@10.150.20.3:5060>
```

When a message containing SDP information arrives, the SIP ALG collects information from the message and translates the IP addresses in the following fields into LSN pool IP addresses and port numbers:

- c= (connection information)

  This field can appear at the session or media level. It appears in the following format:

  c=`<network-type><address-type><connection-address>`

  If the destination IP address is a unicast IP address, the SIP ALG creates pinholes by using the IP address and port numbers specified in the m= field.
- m= (media announcement)

  This field appears at the media level and contains the description of the media. It appears in the following format:

  m=`<media><port><transport><fmt list>`
- a= `(information about the media field)`

  This field can appear at the session or media level, in the following format:

  a=`<attribute>`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a=`<attribute>:<value>`

The following excerpt from a sample SDP section shows the fields that are translated for resource allocation.

o=user 2344234 55234434 IN IP4 10.150.20.3

c=IN IP4 10.150.20.3

m=audio 43249 RTP/AVP 0

The following table shows how SIP payload is translated.

Inbound Request (from public to private)	To	None
	From	None
	Call-ID	None
	Via	None
	Request-URI	Replace LSN pool IP address with private IP address
	Contact	None

	Route	None

Limitations of SIP ALG

A SIP ALG has the following limitations:

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - TD/partitioning
  - Multipart body
  - SIP messages over IPv6 network
  - Line folding

Tested SIP Clients and Proxy Servers

The following SIP clients and proxy server have been tested with SIP ALG:

- **SIP Clients:** X-Lite, Zoiper, Ekiga. Avaya
- **Proxy Server:** openSIPS

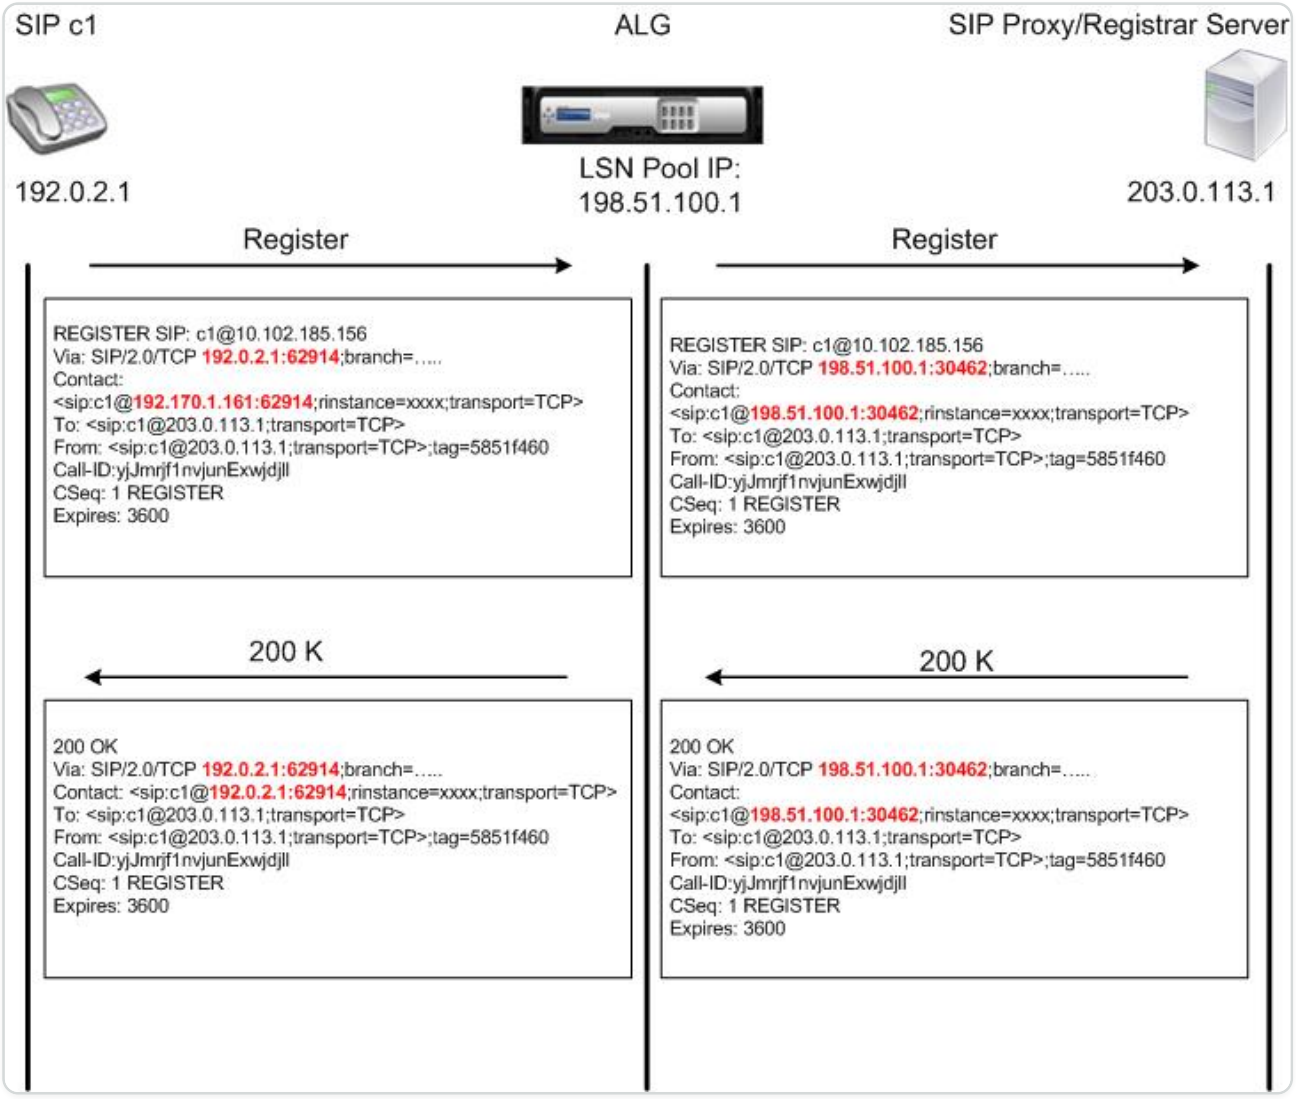
LSN SIP Scenario: SIP Proxy Outside the Private Network (Public Network)

SIP Client Registration

For a typical SIP call, SIP client must register with the SIP registrar by composing a REGISTER request and sending it to the SIP registrar. The NetScaler appliance's SIP ALG intercepts the request, replaces the IP address and port number in the request with the LSN pool IP address and port number provided in the LSN configuration, and forwards the request to the SIP registrar. The SIP ALG then opens a pinhole in the NetScaler configuration to allow further SIP communication between the SIP client and the SIP registrar. The SIP registrar sends a 200 OK response to the SIP client over the LSN pool IP address and port number. The NetScaler appliance captures this response in the pinhole, and the SIP ALG replaces the SIP header, putting the original Contact,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

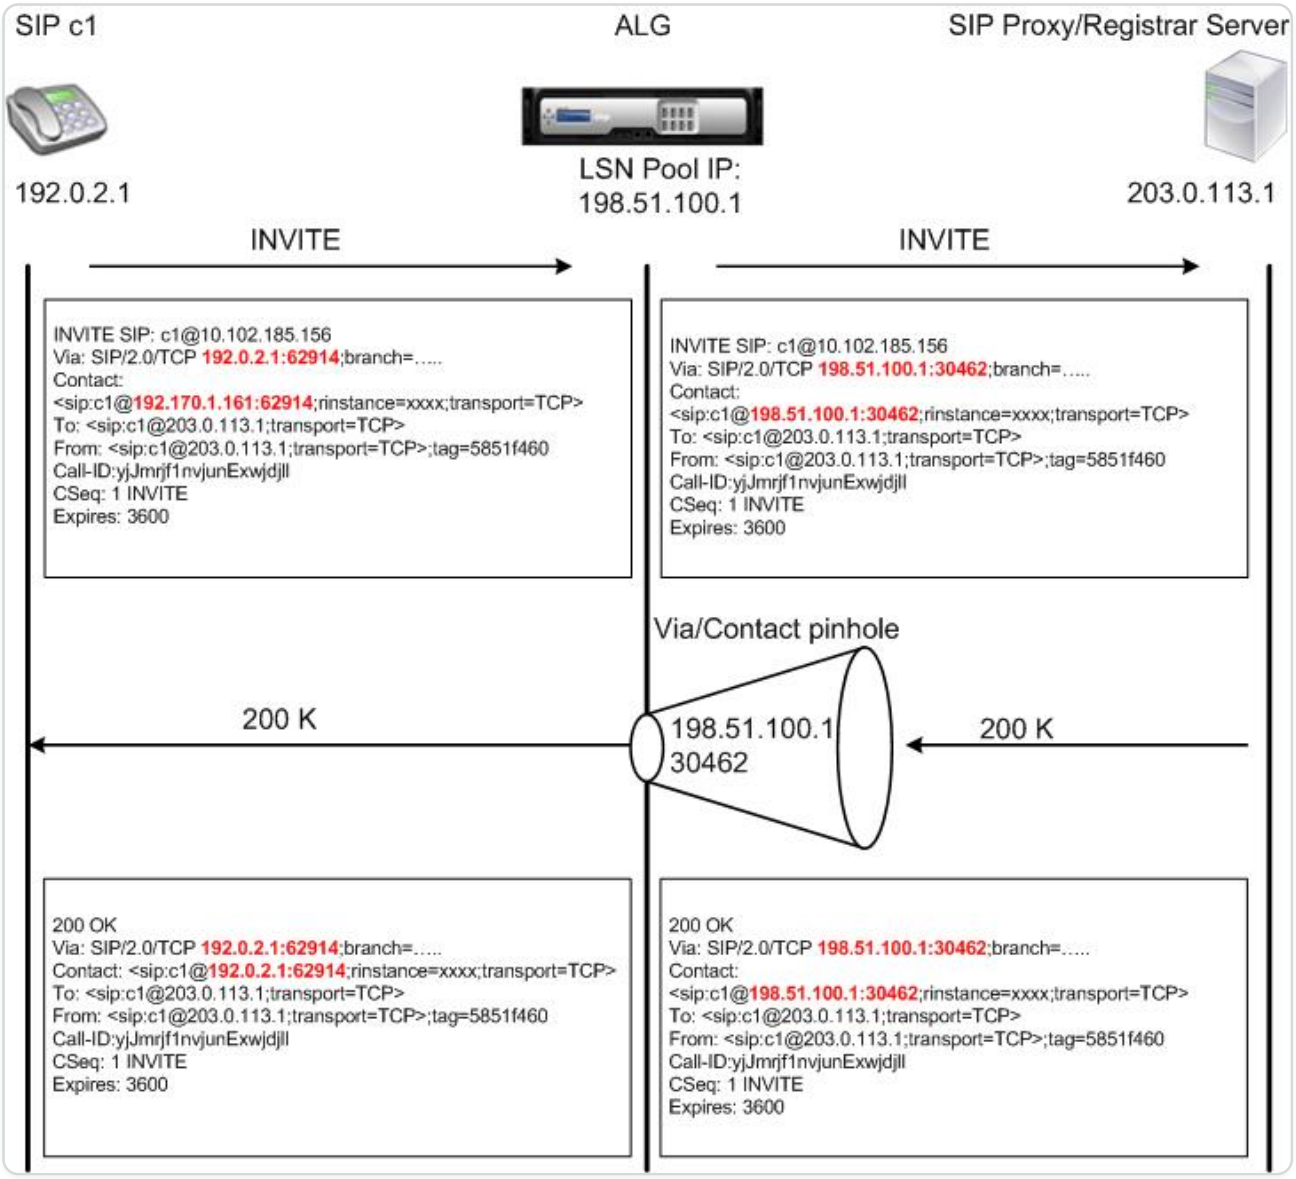
Via, Route, and Record-Route SIP fields back into the message. The SIP ALG then forwards the message to the SIP client. The following figure shows how SIP ALG uses LSN in a SIP call registration flow.



Outgoing Calls

A SIP call is initiated with a SIP INVITE message sent from the internal to the external network. The SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, replacing them with the LSN pool IP address and port number. LSN stores these mappings for subsequent SIP messages in the SIP call. The SIP ALG then opens separate pinholes in the NetScaler configuration to allow SIP and media through the NetScaler appliance on the dynamically assigned ports specified in the SDP and SIP headers. When a 200 OK message arrives at the NetScaler, it is captured by one of the created pinholes. The SIP ALG replaces the SIP header, restoring the original Contact, Via, Route, and Record-Route SIP fields, and then forwards the message to the internal SIP client.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

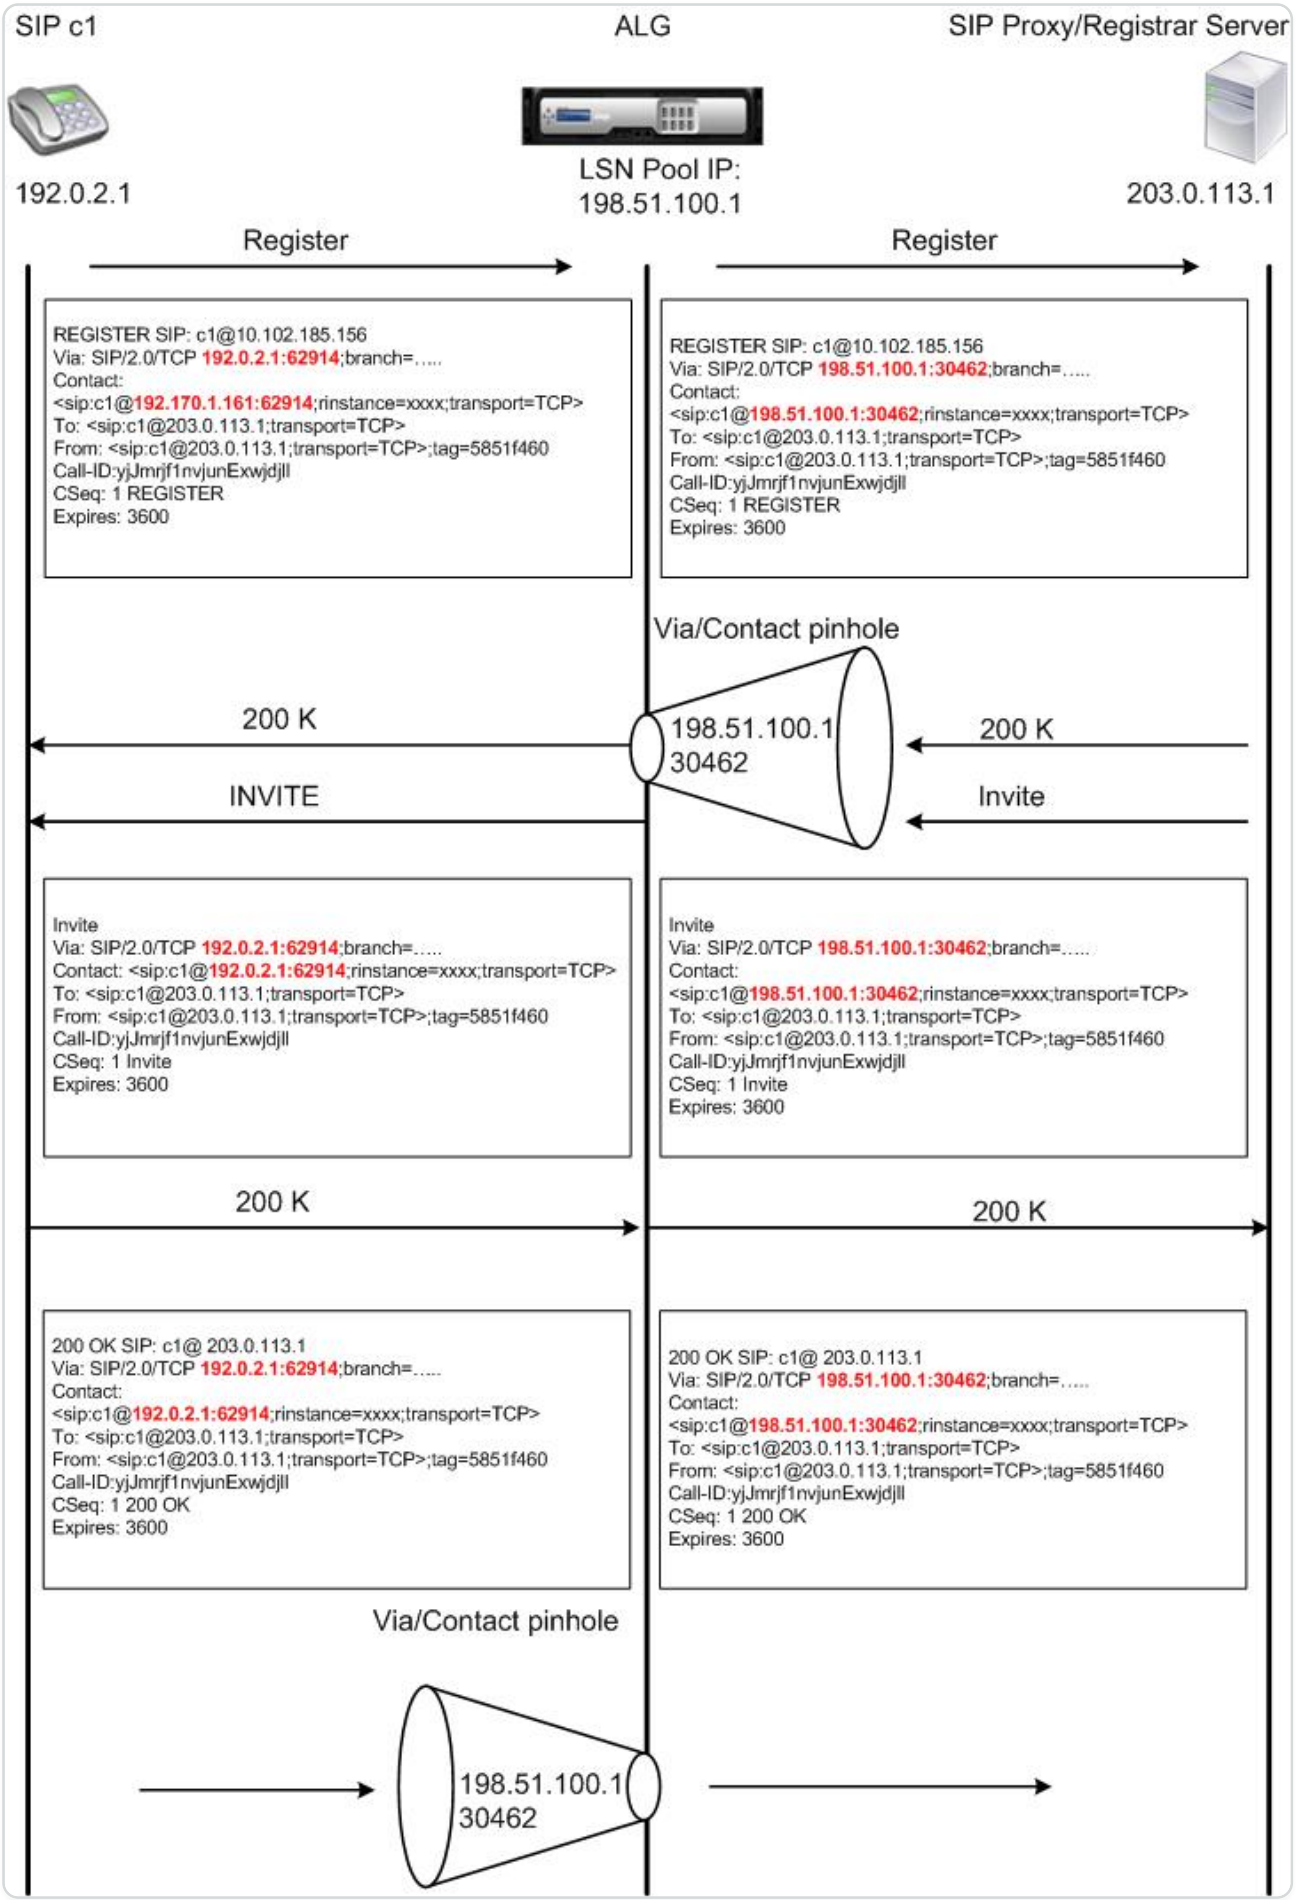


Incoming Calls

A SIP incoming call is initiated with a SIP INVITE message from the external client to the internal network. The SIP registrar forwards the INVITE message to the SIP client in the internal network, using the pinhole that was created when the Internal SIP client registered with the SIP registrar.

The SIP ALG performs NAT on the LSN IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, translating them to the IP address and port number of the internal SIP client, and forwards the request to the SIP client. When the 200 OK response message sent by the internal SIP client arrives at the NetScaler appliance, the SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, translating them to the LSN pool IP address and port number, forwards the response message to the SIP registrar, and then opens a pinhole in the outbound direction for further SIP communication.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Call Termination

The BYE message terminates a call. When the device receives a BYE message, it translates the header fields in the message just as it does for any other message. But because a BYE message must be acknowledged by the receiver with a 200 OK, the ALG delays call teardown for 15 seconds to allow time for transmission of the 200 OK.

Call Between Clients in the Same Network

When both client A and client B in the same network initiate a call, the SIP messages are routed through the SIP proxy in the outside network. The SIP ALG processes the INVITE from client A as a normal outgoing call. Since client B is in the same network, the SIP proxy sends the INIVITE back to the NetScaler appliance. The SIP ALG examines the INIVITE message, determines that it contains the NAT IP address of client A, and replaces that address with the private IP address of client A before sending the message to client B. Once the call is established between the clients, the NetScaler is not involved in the media transmission between the clients.

More LSN SIP Scenarios: SIP Proxy Inside the Private Network

If you want to host the SIP Proxy server inside the private network, Citrix® recommends that you do one of the following:

- Configure a static LSN Mapping for the private SIP proxy. For more information, see Configuring Static LSN Maps. Make sure that the NAT port is the same as the port configured in the SIP ALG profile.
- Configure the SIP Proxy server inside a demilitarized zone (DMZ).

Figure 1. SIP Call Registration

© 1997–2026 Citrix Systems, Inc. All rights reserved.

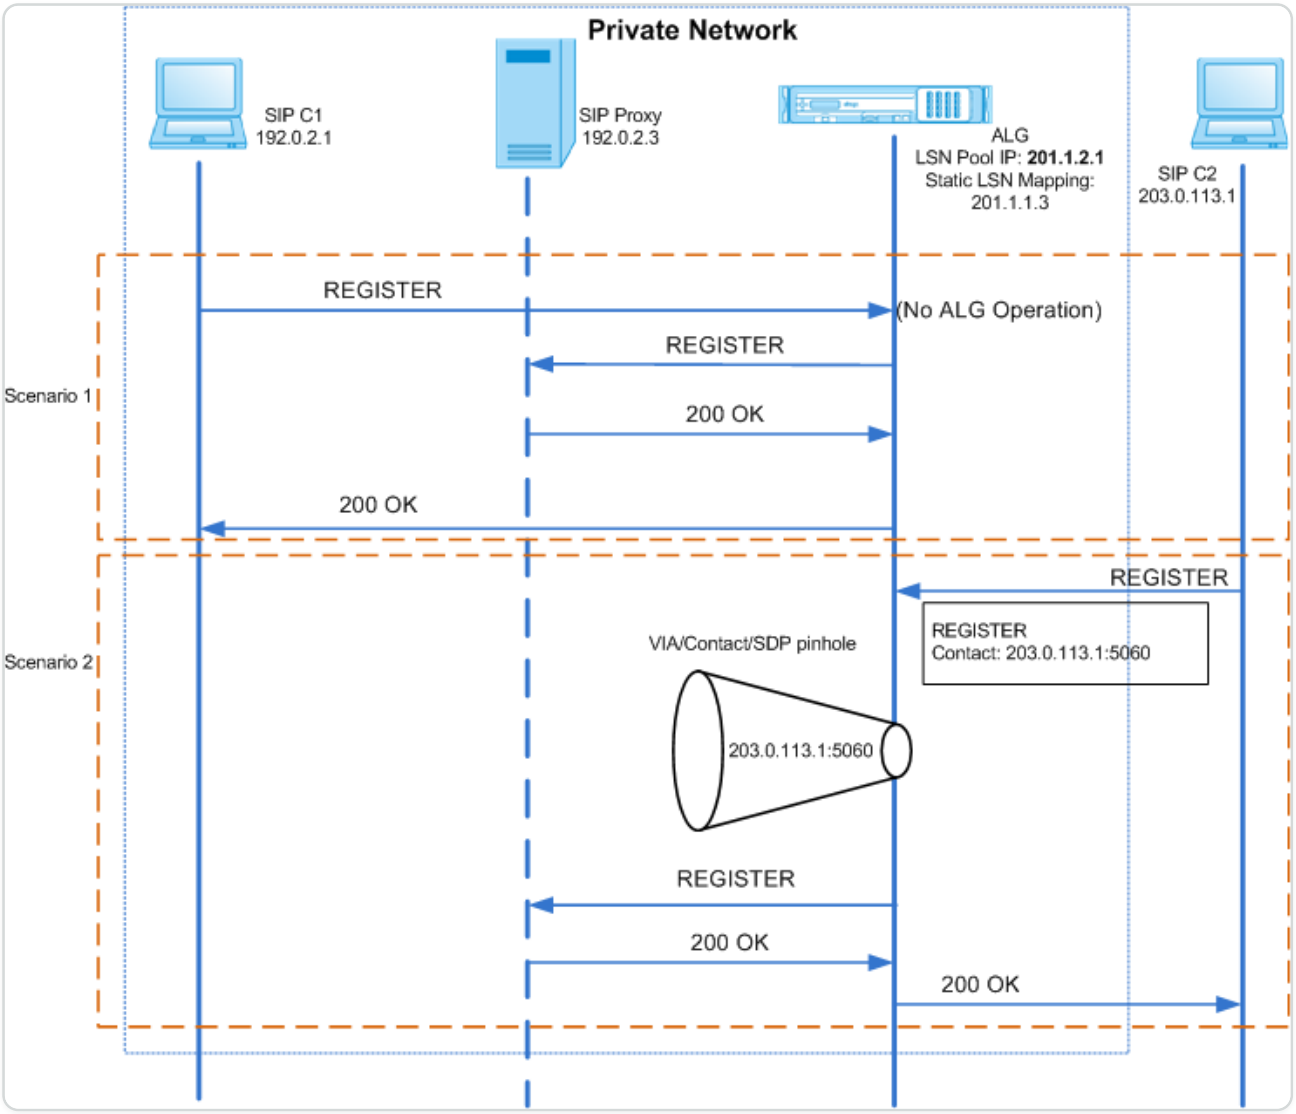


Figure 2. SIP Incoming Call Flow

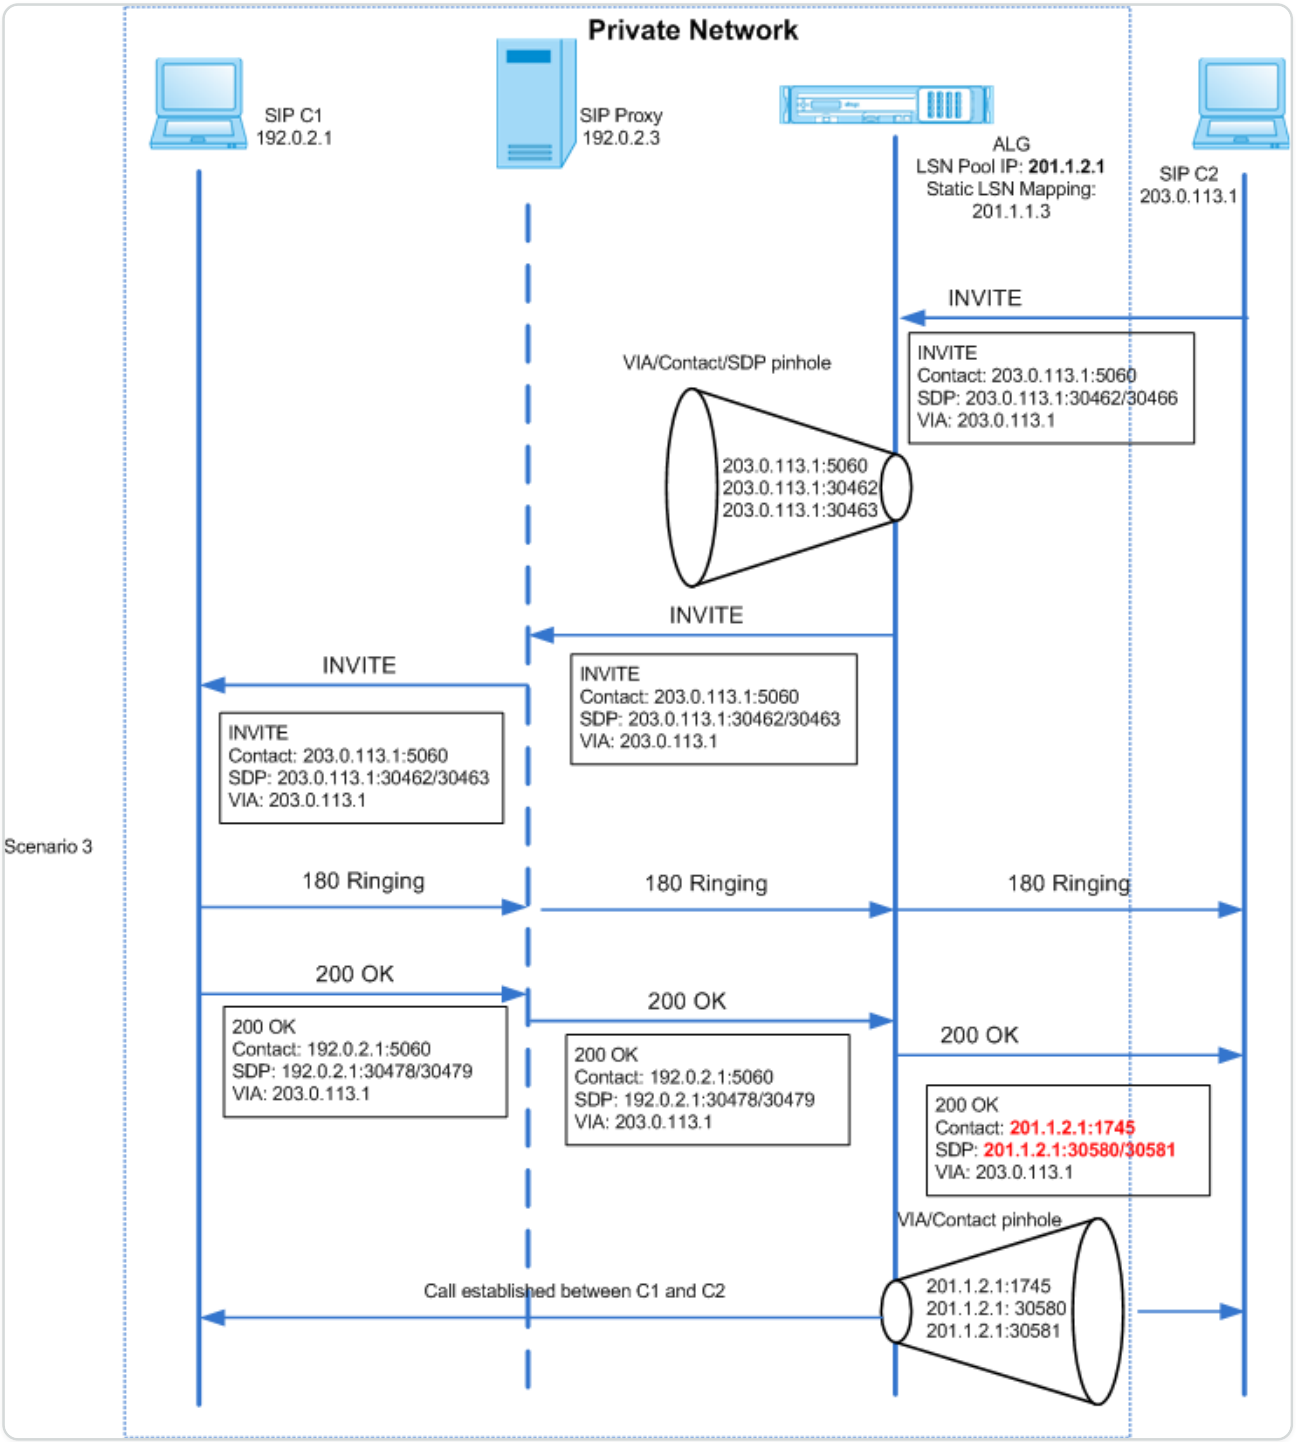
© 1997–2026 Citrix Systems, Inc. All rights reserved.



Figures 1 and 2 show the following scenarios:

- Scenario 1—SIP client in the private network registers with the SIP proxy server in the same network. ALG operations are not performed, because the SIP client and SIP proxy server are in the same network.
- Scenario 2—SIP client in the public network registers with the SIP proxy server in the private network. The REGISTER message from the public SIP client is sent to the NetScaler appliance by using the static LSN mapping configured on the appliance, and the appliance creates a pinhole for further SIP operations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Scenario 3— SIP Incoming call flow. A SIP incoming call is initiated with a SIP INVITE message from the external to the internal network. The NetScaler appliance receives the INVITE message from SIP client C2, which is in the external network, through the static LSN maps configured on the NetScaler appliance.The appliance creates a pinhole and forwards the INVITE message to the SIP proxy. The SIP proxy then forwards the INVITE message to SIP client C1 in the internal network. SIP client C1 then sends 180 and 200 OK messages to the SIP proxy, which in turn forwards the message to SIP client C2 through the NetScaler appliance. When the 200 OK response message sent by internal SIP client C1 arrives at the NetScaler, the SIP ALG performs NAT on the IP addresses and port numbers in the Via, Contact, Route, and Record-Route SIP header fields, and in the SDP fields, replacing them with the LSN pool IP address and port number. The SIP ALG then forwards the response message to SIP client C2 and opens a pinhole in the outbound direction for further SIP communication.

Support for Audit Logs

You can log ALG information as part of LSN logging by enabling ALG in the LSN audit logging configuration. For more information on LSN logging, see Logging and Monitoring LSN. A log message for an ALG entry in the LSN log consists of the following information:

- Time stamp
- Type of SIP message (for example, SIP request)
- Source IP address and port of the SIP client
- Destination IP address and port of the SIP proxy
- NAT IP address and port
- SIP method
- Sequence number
- Whether or not the SIP client is registered
- Caller’s user name and domain
- Receiver’s user name and domain

Sample audit log:

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Steps for LSN. While configuring LSN, make sure that you:

- Set the following parameters while adding the LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT

Important: For the SIP ALG to work, a full cone NAT configuration is mandatory.

Example:

```
add lsn appsprofile app_tcp TCP -ippooling PAIRED -mapping ENDPOINT-
INDEPENDENT -filtering ENDPOINT-INDEPENDENT
```

- Create a SIP ALG profile and make sure that you define either the source port range or destination port range.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example:

```
add lsn sipalgprofile sipalgprofile_tcp -sipsrcportrange 1-65535
-sipdstportrange 5060 -openViaPinhole ENABLED -openRecordRoutePinhole
ENABLED –sipTransportProtocol TCP
```

- Set SIP ALG = ENABLED, while creating the LSN group.

Example:

```
add lsn group g1 -clientname c1 -sipalg ENABLED
```

- Bind the SIP ALG profile to the LSN group.

Sample SIP ALG Configuration:

The following sample configuration shows how to create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, SIP ALG specific setting, and configure SIP ALG:

```
add lsn pool p1

Done

bind lsn pool p1 10.102.185.190

Done

add lsn client c1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn client c1 -network 192.170.1.0 -netmask 255.255.255.0

Done

add lsn appsprofile app_tcp TCP -ippooling PAIRED -mapping ENDPOINT-
INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn appsprofile app_udp UDP -ippooling PAIRED -mapping ENDPOINT-
INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile app_tcp 1-65535

Done

bind lsn appsprofile app_udp 1-65535

Done

add lsn sipalgprofile sipalgprofile_tcp -sipdstportrange 5060
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-openViaPinhole ENABLED -openRecordRoutePinhole ENABLED –
sipTransportProtocol TCP

Done

add lsn sipalgprofile sipalgprofile_udp -sipdstportrange 5060
-openViaPinhole ENABLED -openRecordRoutePinhole ENABLED
-sipTransportProtocol UDP

Done

add lsn group g1 -clientname c1 -sipalg ENABLED

Done

bind lsn group g1 -poolname p1

Done

bind lsn group g1 -appsprofilename app_tcp

Done

bind lsn group g1 -appsprofilename app_udp
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group g1 -sipalgprofilename sipalgprofile_tcp

Done

bind lsn group g1 -sipalgprofilename sipalgprofile_udp

Done
```

Application Layer Gateway for RTSP Protocol

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. NetScaler functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to NetScaler owned public IP address called an LSN pool IP address.
- Inbound response—LSN pool IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

RTSP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

Limitations of RTSP ALG

The RTSP ALG does not support the following:

- Multicast RTSP sessions
- RTSP session over UDP
- TD/admin partitioning
- RSTP Authentication
- HTTP tunneling

RTSP and LSN scenario

Typically, a RTSP SETUP request specifies how a single media stream must be transported. The request contains the media stream URL and a transport specifier. This specifier typically includes one local port for receiving RTP data (audio or video), and another for receiving RTCP data (meta information). The server reply usually confirms the chosen parameters and fills in the missing parts, such as the server's chosen ports. Each media stream must be configured by using the SETUP command before an aggregate play request can be sent.

In a typical RTSP communication, the media client in the public network sends a SETUP request to the media server in the private network. RSTP ALG intercepts the request and, in the media stream, replaces the public IP address and port number with the LSN pool IP address and LSN port number.

The media server in the private network uses the LSN pool IP address and LSN port number to send a 200 OK response to the media client in the public network. The NetScaler RTSP ALG intercepts the response and replaces the LSN pool IP address and LSN port number with the public IP address and port number of the media client.

Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Steps for LSN. While configuring LSN, make sure that you:

- Set the **NAT Type** as DETERMINSTIC or DYNAMIC while adding the LSN pool.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Set the following parameters while adding the LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

Sample RTSP ALG Configuration:

The following sample configuration shows how to create a simple LSN configuration with a single subscriber network, single LSN NAT IP address, and RTSP ALG settings:

```
enable ns feature WL SP LB CS LSN

Done

add lsn pool pool1 -nattype DETERMINISTIC

Done

bind lsn pool pool1 10.102.218.246

Done

add lsn client client1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn client client1 -network 200.200.200.11 -netmask 255.255.255.0

Done

add lsn appsprofile app1 TCP -ippooling PAIRED -mapping ENDPOINT-
INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn appsprofile app2 UDP -ippooling PAIRED -mapping ENDPOINT-
INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

bind lsn appsprofile app1 1-65535

Done

bind lsn appsprofile app2 1-65535

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn rtspalgprofile rtspalgprofiledefault -rtspIdleTimeout 1000
-rtspportrange 554

Done

add lsn group group1 -clientname client1 -nattype DETERMINISTIC
-portblocksize 512 -rtspalg ENABLED

Done

bind lsn group group1 -poolname pool1

Done

bind lsn group group1 -appsprofilename app1

Done

bind lsn group group1 -appsprofilename app2

Done

bind lsn group group1 -rtspalgprofilename rtspalgprofiledefault
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Application Layer Gateway for IPSec Protocol

If communication between two network devices (for example, client and server) uses the IPSec protocol, IKE traffic (which is over UDP) uses port fields, but Encapsulating Security Payload (ESP) traffic does not. If a NAT device on the path assigns the same NAT IP address (but different ports) to two or more clients at the same destination, the NAT device is unable to distinguish and properly route the return ESP traffic does not contain port information. Therefore, IPSec ESP traffic fails at the NAT device.

NAT-Traversal (NAT-T) capable IPSec endpoints detect the presence of an intermediate NAT device during IKE phase 1 and switch to UDP port 4500 for all subsequent IKE and ESP traffic (encapsulating ESP in UDP). Without NAT-T support on the peer IPSec endpoints, IPSec protected ESP traffic is transmitted without any UDP encapsulation. Therefore, IPSec ESP traffic fails at the NAT device.

The NetScaler appliance supports IPSec application layer gateway (ALG) functionality for large scale NAT configurations. The IPSec ALG processes IPSec ESP traffic and maintains session information so that the traffic does not fail when the IPSec endpoints do no support NAT-T (UDP encapsulation of ESP traffic).

How IPSec ALG Works

An IPSec ALG monitors IKE traffic between a client and the server, and permits only one IKE phase 2 message exchange between the client and the server at any given time.

Once the two-way ESP packets are received for a particular flow, the IPSec ALG creates a NAT session for this particular flow so that subsequent ESP traffic can flow smoothly. The ESP traffic is identified by Security Parameters Indexes (SPIs), which are unique for a flow and for each direction. An IPSec ALG uses ESP SPIs in place of source and destination ports for performing large scale NAT.

If a gate receives no traffic, it times out. After both gates time out, another IKE phase 2 exchange is permitted.

IPSec ALG Timeouts

IPsec ALG on a NetScaler appliance has three timeout parameters:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **ESP Gate Timeout**. Maximum time that the NetScaler appliance blocks an IPSec ALG gate for a particular client on a specific NAT IP address for a given server if no two-way ESP traffic is exchanged between the client and the server.
- **IKE Session Timeout**. Maximum time that the NetScaler appliance keeps the IKE session information before removing it if there is no IKE traffic for that session.
- **ESP Session Timeout**. Maximum time that NetScaler appliance keeps the ESP session information before removing it if there is no ESP traffic for that session.

Points to Consider before Configuring IPSec ALG

Before you start configuring IPSec ALG, consider the following points:

- You must understand the different components of IPSec protocol.
- IPSec ALG is not supported for DS-Lite and Large scale NAT64 configurations.
- IPSec ALG is not supported for hairpin LSN flow.
- IPSec ALG does not work with RNAT configurations.
- IPSec ALG is not supported in NetScaler clusters.

Configuration Steps

Configuring IPSec ALG for large scale NAT44 on a NetScaler appliance consists of the following tasks:

- **Create an LSN application profile and bind it to the LSN configuration.** Set the following parameters while configuring an application profile:
  - Protocol=UDP
  - IP Pooling = PAIRED
  - Port=500

Bind the application profile to the LSN group of an LSN configuration. For instructions on creating an LSN configuration, see Configuration Steps for LSN.

- **Create an IPSec ALG profile**. An IPSec profile includes various IPSec timeouts, such as IKE session timeout, ESP session timeout, and ESP gate timeout. You bind an IPSec ALG profile to an LSN group. An IPSec ALG profile has the following default settings:
  - IKE session timeout = 60 minutes
  - ESP session timeout = 60 minutes

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- ESP gate timeout = 30 seconds

- **Bind the IPSec ALG profile to the LSN configuration**. IPSec ALG is enabled for an LSN configuration when you bind an IPSec ALG profile to the LSN configuration. Bind the IPSec ALG profile to the LSN configuration by setting the IPSec ALG profile parameter to the name of the created profile in the LSN group. An IPSec ALG profile can be bound to multiple LSN groups, but an LSN group can have only one IPSec ALG profile.

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> UDP -ippooling PAIRED

show lsn appsprofile
```

To bind destination port to the LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
```

To bind an LSN application profile to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -appsprofilename <string>

show lsn group
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create an IPSec ALG profile by using the CLI

At the command prompt, type:

```
add ipsecalg profile <name> [-ikeSessionTimeout <positive_integer>] [-
espSessionTimeout <positive_integer>] [-espGateTimeout <positive_integer>]
[-connfailover ( ENABLED | DISABLED)

show ipsecalg profile <name>
```

To bind an IPSec ALG profile to an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname> -poolname <string> - ipsecAlgProfile <string>

show lsn group <name>
```

To create an LSN application profile and bind it to an LSN configuration by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Application** tab, add an LSN application profile and bind it to an LSN group.

To create an IPSec ALG profile by using the GUI**

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **IPSEC ALG** tab, and then add an IPSec ALG profile.

To bind an IPSec ALG profile to an LSN configuration by using the GUI**

1. Navigate to **System** > **Large Scale NAT** > **LSN Group**, open the LSN group.
2. In **Advanced Settings**, click **+ IPSEC ALG Profile** to bind the created IPSec ALG profile to the LSN group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Sample Configuration

In the following sample large scale NAT44 configuration, IPSec ALG is enabled for subscribers in the 192.0.2.0/24 network. IPSec ALG profile IPSECALGPROFILE-1 with various IPSec timeout settings is created and is bound to LSN group LSN Group -1.

Sample configuration:

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.9

Done

add lsn appsprofile LSN-APPSPROFILE-1 UDP -ippooling PAIRED
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn appsprofile LSN-APPSPROFILE-1 500

Done

add ipsecalg profile  IPSECALGPROFILE-1 -ikeSessionTimeout 45 –
espSessionTimeout 40 –espGateTimeout 20 -connfailover ENABLED

Done

bind lsn group LSN-GROUP-1 -appsprofilename LSN-APPSPROFILE-1

Done

bind lsn group LSN-GROUP-1 -poolname LSN-POOL-1

Done

bind lsn group LSN-GROUP-1 - ipsecAlgProfile IPSECALGPROFILE-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Logging and Monitoring LSN

You can log LSN information to diagnose, troubleshoot problems, and to meet legal requirements. You can monitor the performance of the LSN feature by using LSN statistical counters and displaying current LSN sessions.

Logging LSN

Logging LSN information is one of the important functions required by the ISPs to meet legal requirements and for identifying the source of traffic at any given time.

A NetScaler appliance logs LSN mapping entries and the LSN sessions created or deleted for each LSN group. You can control logging of LSN information for an LSN group by using the logging and session logging parameters of the LSN group. These are group level parameters and are disabled by default. The NetScaler appliance logs LSN sessions for an LSN group only when both logging and session logging parameters are enabled.

The following table displays the logging behavior for an LSN group for various settings of logging and session logging parameters.

LOGGING	SESSION LOGGING	LOGGING BEHAVIOR
Enabled	Enabled	Logs LSN mapping entries as well as LSN sessions.
Enabled	Disabled	Logs LSN mapping entries but not LSN sessions.
Disabled	Enabled	Logs neither mapping entries nor LSN sessions.

A log message for an LSN mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp
- Entry type (MAPPING)
- Whether the LSN mapping entry was created or deleted

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for an LSN session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp
- Entry type (SESSION)
- Whether the LSN session is created or removed
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The appliance uses its existing syslog and audit log framework to log LSN information. You must enable global level LSN logging by enabling the LSN parameter in the related NSLOG action and SYLOG action entities. When the Logging parameter is enabled, the NetScaler appliance generates log messages related to LSN mappings and LSN sessions of this LSN group. The appliance then sends these log messages to servers associated with the NSLOG action and SYSLOG action entities.

For logging LSN information, Citrix® recommends:

- Logging the LSN information on external log servers instead of on the NetScaler appliance. Logging on external servers facilitates optimal performance when the appliance creates large amounts of LSN log entries (in order of millions).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Using SYSLOG over TCP, or NSLOG. By default SYSLOG uses UDP, and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data.

  Note:

  - The SYSLOG generated on NetScaler appliance are dynamically sent to the external log servers.
  - When using SYSLOG over TCP, if the TCP connection is down or the SYSLOG server is busy, then the NetScaler appliances stores the logs in buffer and send the data once the connection is active.

For more information about configuring logging, see Audit Logging.

Configuring LSN logging consists of the following tasks:

- **Configuring the NetScaler appliance for logging.** This task involves creating and setting various entities and parameters of the NetScaler appliance:
  - **Create a SYSLOG or NSLOG audit logging configuration**. Creating an audit logging configuration involves the following tasks:
    - Create a NSLOG or SYSLOG audit action and enable the LSN parameter. Audit actions specify the IP addresses of log servers.
    - Create a SYSLOG or NSLOG audit policy and bind the audit action to the audit policy. Audit actions specify the IP addresses of log servers. Optionally, you can set the transport method for log messages that are sent to the external log servers. By default UDP is selected, you can set the transport method as TCP for a reliable transport mechanism.Bind the audit policy to system global.
    - Create a SYSLOG or NSLOG audit policy and bind the audit action to the audit policy.
    - Bind the audit policy to system global. **Note**: For an existing audit logging configuration, just enable the LSN parameter for logging LSN information in the server specified by the audit action.
  - **Enable logging and session logging parameters.** Enable logging and session logging parameters either as you add LSN groups or after you have created the groups. The NetScaler appliance generates log messages related to these LSN groups and sends them to the server of those audit actions that have the LSN parameter enabled.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Configuring log servers.** This task involves installing SYSLOG or NSLOG packages on the desired servers. This task also involves specifying the NSIP address of the NetScaler appliance in the configuration file of SYSLOG or NSLOG. Specifying the NSIP address enables the server to identify the log information sent by the NetScaler appliance for storing them in a log file.

For more information about configuring logging, see Audit Logging.

SYSLOG Configuration Using the CLI

To create a SYSLOG server action for LSN logging by using the command line interface

At the command prompt, type:

```
add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel
<logLevel>... [-transport (TCP)] [-lsn ( ENABLED | DISABLED )]
```

To create a SYSLOG server policy for LSN logging by using the CLI

At the command prompt, type:

```
add audit syslogPolicy <name> <rule> <action>
```

To bind a SYSLOG server policy to system global for LSN logging by using the CLI

At the command prompt, type:

```
bind system global [<policyName> [-priority <positive_integer>]]
```

SYSLOG Configuration Using the Configuration Utility

To configure a SYSLOG server action for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Syslog** and, on the Servers tab, add a new auditing server or edit an existing server.
2. To enable LSN logging, select the **Large Scale NAT Logging** option.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. (Optional) To enable SYSLOG over TCP, select the **TCP Logging** option.

To configure a SYSLOG server policy for LSN logging by using the configuration utility

Navigate to **Systems** > **Auditing** > **Syslog** and, on the **Policies** tab, add a new policy or edit an existing policy.

To bind a SYSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Syslog**.
2. On the **Policies** tab, in the **Action** list, click **Global Bindings** to bind the audit global policies.

NSLOG Configuration Using the CLI

To create a NSLOG server action for LSN logging by using the CLI

At the command prompt, type:

```
add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel
<logLevel> ... [-lsn ( ENABLED | DISABLED )]
```

To create a NSLOG server policy for LSN logging by using the CLI

At the command prompt, type:

```
add audit nslogPolicy <name> <rule> <action>
```

To bind a NSLOG server policy to system global for LSN logging by using the CLI

At the command prompt, type:

```
bind system global [<policyName>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NSLOG Configuration Using the Configuration Utility

To configure a NSLOG server action for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Nslog** and, on the **Servers** tab, add a new auditing server or, edit an existing server.
2. To enable LSN logging, select the **Large Scale NAT Logging** option.

To configure a NSLOG server policy for LSN logging by using the configuration utility

Navigate to **Systems** > **Auditing** > **Nslog** and, on the **Policies** tab, add a new policy or edit an existing policy.

To bind a NSLOG server policy to system global for LSN logging by using the configuration utility

1. Navigate to **Systems** > **Auditing** > **Nslog**.
2. On the **Policies** tab, in the **Action** list, click **Global Bindings** to bind the audit global policies.

Example

The following configuration specifies two SYSLOG and two NSLOG servers for storing log entries including LSN logs. LSN Logging is configured for LSN groups LSN-GROUP-2 and LSN-GROUP-3.

The NetScaler appliance generates log messages related to LSN mappings and LSN sessions of these LSN groups, and sends them to the specified log servers.

```
add audit syslogAction SYS-ACTION-1 198.51.101.10 -logLevel ALL -lsn
ENABLED

Done

add audit syslogPolicy SYSLOG-POLICY-1 ns_true SYS-ACTION-1

Done

bind system global SYSLOG-POLICY-1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add audit syslogAction SYS-ACTION-2 198.51.101.20 -logLevel ALL -lsn
ENABLED

Done

add audit syslogPolicy SYSLOG-POLICY-2 ns_true SYS-ACTION-2

Done

bind system global SYSLOG-POLICY-2

Done

add audit nslogAction NSLOG-ACTION-1 198.51.101.30 -logLevel ALL -lsn
ENABLED

Done

add audit nslogPolicy NSLOG-POLICY-1 ns_true NSLOG-ACTION-1

Done

bind system global NSLOG-POLICY-1

Done

add audit nslogAction NSLOG-ACTION-2 198.51.101.40 -logLevel ALL -lsn
ENABLED

Done

add audit nslogPolicy NSLOG-POLICY-2 ns_true NSLOG-ACTION-2

Done

bind system global NSLOG-POLICY-2

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn group LSN-GROUP-3 -clientname LSN-CLIENT-2 –logging ENABLED –
sessionLogging ENABLED

Done

set lsn group LSN-GROUP-2  –logging ENABLED –sessionLogging ENABLED

Done
```

The following configuration specifies SYSLOG configuration for sending log messages to the external SYSLOG server 192.0.2.10 using TCP.

```
add audit syslogAction SYS-ACTION-1 192.0.2.10 -logLevel ALL -transport
TCP

Done

add audit syslogPolicy SYSLOG-POLICY-1 ns_true SYS-ACTION-1

Done

bind system global SYSLOG-POLICY-1

Done
```

The following table displays sample LSN log entries of each type stored on the configured log servers. These LSN log entries are generated by a NetScaler appliance whose NSIP address is 10.102.37.115.

LSN LOG ENTRY TYPE	SAMPLE LOG ENTRY
LSN session creation	Local4.Informational 10.102.37.115 08/05/2014:09:59:48 GMT 0-PPE-0 : LSN LSN_SESSION 2581750 : SESSION CREATED Client IP:Port:TD 192.0.2.10: 15136:0, NatIP:NatPort 203.0.113.6: 6234,

Minimal Logging

Deterministic LSN configurations and Dynamic LSN configurations with port block significantly reduces the LSN log volume. For these two types of configuration, the NetScaler appliance allocates a NAT IP address and a block of ports to a subscriber. The NetScaler appliance generates a log message for a port block at the time of allocation to a subscriber. The NetScaler appliance also generates a log message when a NAT IP address and port block is freed. For a connection, a subscriber can be identified just by its mapped NAT IP address and port block. Because of this reason, the NetScaler appliance does not log any LSN session created or deleted. The appliance also neither logs any mapping entry created for a session nor when the mapping entry gets removed.

The minimal logging feature for deterministic LSN configurations and dynamic LSN configurations with port block is enabled by default and there is no provision to disable it. In other words, the NetScaler appliance automatically do minimal logging for deterministic LSN configurations and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

dynamic LSN configurations with port block. There is no option available for disabling this feature. The appliance sends the log messages to all the configured log servers.

A log message for each port block consists of the following information:

- NSIP address of the NetScaler appliance
- Time stamp
- Entry type as DETERMINISTIC or PORTBLOCK
- Whether a port block is allocated or is freed
- Subscriber's IP address and the assigned NAT IP address and port block
- Protocol name

Minimal Logging for Deterministic LSN Configuration

Consider an example of a simple deterministic LSN configuration for four subscribers having the IP address 192.0.17.1, 192.0.17.2, 192.0.17.3, and 192.0.17.4.

In this LSN configuration, the port block size is set to 32768 and LSN NAT IP address pool has IP addresses in the range 203.0.113.19-203.0.113.23.

```
add lsn client LSN-CLIENT-7

Done

bind lsn client LSN-CLIENT-7 -network 192.0.17.0 -netmask 255.255.255.253

Done

add lsn pool LSN-POOL-7 -nattype DETERMINISTIC

Done

bind lsn pool LSN-POOL-7 203.0.113.19-203.0.113.23

Done

add lsn group LSN-GROUP-7 -clientname LSN-CLIENT-7 -nattype DETERMINISTIC
-portblocksize 32768

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group LSN-GROUP-7 -poolname LSN-POOL-7

Done
```

The NetScaler appliance sequentially preallocates, from the LSN NAT IP pool and on the basis of the set port block size, an LSN NAT IP address and a block of ports to each subscriber. It assigns the first block of ports (1024-33791) on the beginning NAT IP address (203.0.113.19) to the beginning subscriber IP address (192.0.17.1). The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT IP address is assigned to the subscriber, and so on. The appliance logs the NAT IP address and the block of ports allocated for each subscriber.

The NetScaler appliance does not log any LSN session created or deleted for these subscribers. The appliance generates the following log messages for the LSN configuration.

```
1) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
LSN_DETERMINISTIC 79201453 0 :  Dtrstc ALLOC Client 12.0.0.241, NatInfo
50.0.0.2:59904 to 60415

2) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
LSN_DETERMINISTIC 79201454 0 :  Dtrstc ALLOC Client 12.0.0.242, NatInfo
50.0.0.2:60416 to 60927

3) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
LSN_DETERMINISTIC 79201455 0 :  Dtrstc ALLOC Client 12.0.0.243, NatInfo
50.0.0.2:60928 to 61439

4) 03/23/2015:00:30:56 GMT  Informational 0-PPE-0 : default LSN
LSN_DETERMINISTIC 79201455 0 :  Dtrstc ALLOC Client 12.0.0.243, NatInfo
50.0.0.2:60928 to 61439
```

When you remove the LSN configuration, the allocated NAT IP address and block of ports is freed from each subscriber. The appliance logs NAT IP address and block of ports freed from each subscriber. The appliance generates the following log messages for each subscriber when you remove the LSN configuration.

```
1) 03/23/2015:00:33:57 GMT  Informational 0-PPE-0 : default LSN
LSN_DETERMINISTIC 79201706 0 :  Dtrstc FREE Client 12.0.0.238, NatInfo

50.0.0.2:59392 to 59903
```

Minimal Logging for Dynamic LSN Configuration with Port Block

Consider an example of a simple dynamic LSN configuration with port block for any subscriber in the network 192.0.2.0/24. In this LSN configuration, the port block size is set to 1024 and LSN NAT IP address pool has IP addresses in the range 203.0.113.3-203.0.113.4.

```
set lsn parameter -memLimit 4000

Done

add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.4

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1 -portblocksize 1024

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

The NetScaler appliance allocates a random NAT IP address and a block of ports, from the LSN NAT IP pool and on the basis of the set port block size, for a subscriber when it initiates a session for the first time. The NetScaler logs the NAT IP address and block of ports allocated to this subscriber. The appliance does not log any LSN session created or deleted for this subscriber. If all the ports are allocated (for different subscriber's sessions) from the subscriber's allocated port block, the appliance allocates a new random NAT IP address and port block for the subscriber for additional sessions. The NetScaler logs every NAT IP address and port block allocated to a subscriber.

The appliance generates the following log message when the subscriber, having the IP address 192.0.2.1, initiates a session. The log message shows that the appliance has allocated NAT IP address 203.0.113.3 and port block 1024-2047 to the subscriber.

```
03/23/2015:00:07:12 GMT  Informational 0-PPE-3 : default LSN LSN_PORTBLOCK
106725793 0 :  Portblock ALLOC Client 12.0.2.72, NatInfo 203.0.113.3:1024
to 2047, Proto:TCP
```

Once there are no more sessions left that is using the allocated NAT IP address and one of the ports in the allocated port block, the allocated NAT IP address and block of ports is freed from the subscriber. The NetScaler logs that the NAT IP address and the block of ports is freed from the subscriber. The appliance generates the following log messages for the subscriber, having the IP address 192.0.2.1 , when no more sessions are left that is using the allocated NAT IP address (203.0.113.3) and a port from the allocated port block (1024-2047). The log message shows that the NAT IP address and port block are freed from the subscriber.

```
03/23/2015:00:11:09 GMT Informational 0-PPE-3 : default LSN LSN_PORTBLOCK
106814342 0 :  Portblock FREE Client 12.0.3.122, NatInfo 203.0.113.3: 1024
to 2047, Proto:TC
```

Load Balancing SYSLOG Servers

The NetScaler appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the NetScaler appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance

© 1997–2026 Citrix Systems, Inc. All rights reserved.

and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the CLI

Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

```
add service <name>(<IP> | <serverName>) <serviceType (SYSLOGTCP |
SYSLOGUDP)> <port>
```

Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

```
add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod
<AUDITLOGHASH>]
```

Bing the service to the load balancing virtual server.

```
Bind lb vserver <name> <serviceName>
```

Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

```
add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel
<logLevel>]
```

Add a SYSLOG policy by specifying the rule and action.

```
add syslogpolicy <name> <rule> <action>
```

Bind the SYSLOG policy to the system global for the policy to take effect.

```
bind system global <policyName>
```

Load balancing of SYSLOG servers using the configuration utility

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Navigate to Traffic Management > Services, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to Traffic Management > Virtual Servers, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

3. Bing the service to the load balancing virtual server to the service.

   Bing the service to the load balancing virtual server.

   Navigate to Traffic Management > Virtual Servers, select a virtual server and then selectAUDITLOGHASH in the Load Balancing Method.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to System > Auditing, click Servers and add a server by selecting LB Vserver option inServers.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to System > Syslog, click Policies and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to System > Syslog, select a SYSLOG policy and click Action, and then click Global Bindings and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. The NetScaler appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514

Done

add service service2 192.0.2.11 SYSLOGUDP 514
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add service service3 192.0.2.11 SYSLOGUDP 514

Done

add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH

Done

bind lb vserver lbvserver1 service1

Done

bind lb vserver lbvserver1 service2

Done

bind lb vserver lbvserver1 service3

Done

add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All

Done

add syslogpolicy syspol1 ns_true sysaction1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind system global syspol1

Done
```

Logging HTTP Header Information

The NetScaler appliance can now log request header information of an HTTP connection that is using the LSN fucntionality of the NetScaler. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to.
- HTTP Method specified in the HTTP request.
- HTTP version used in the HTTP request.
- IP address of the subscriber that sent the HTTP request.

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set a subscribers. For example, an ISP can use this feature to find out the most popular websites among a set of subscribers.

An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging. The HTTP header log profile is then bound to an LSN group. The NetScaler appliance then logs HTTP header attributes, which are enabled in the bound HTTP header log profile for logging, of any HTTP requests related to the LSN group. The appliance then sends the log messages to the configured log servers.

An HTTP header log profile can be bound to multiple LSN groups but an LSN group can have only one HTTP header log profile.

To create an HTTP header log profile by using the the CLI

At the command prompt, type:

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED |
DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion ( ENABLED |
DISABLED )] [-logHost ( ENABLED | DISABLED )]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn httphdrlogprofile
```

To bind an HTTP header log profile to an LSN group by using the the CLI

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
```

Example

In the following example of an LSN configuration, HTTP header log profile HTTP-Header-LOG-1 is bound to LSN group LSN-GROUP-1. The log profile has all the HTTP attributes (URL, HTTP method, HTTP version, and HOST IP address) enabled for logging so that all these attributes are logged for any HTTP requests from subscribers (in the network 192.0.2.0/24) related to the LSN group.

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1

Done

set lsn parameter -memLimit 4000

Done

add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3-203.0.113.4

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1 -portblocksize 1024

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done

bind lsn group  LSN-GROUP-1  -httphdrlogprofilename HTTP-HEADER-LOG-1

Done
```

The NetScaler generates the following HTTP header log message when one of the subscriber belonging to the LSN configuration example sends an HTTP request.

The log message tells us that a client having the IP address 192.0.2.33 sends an HTTP request to URL example.com using HTTP method GET and HTTP version 1.1.

```
03/19/2015:16:24:04 GMT  Informational 0-PPE-1 : default LSN Message 59
0 :  "LSN Client IP:TD 10.102.37.118:0 URL: example.com Host: 192.0.2.33
Version: HTTP1.1 Method: GET"
```

Logging MSISDN Information

A Mobile Station Integrated Subscriber Directory Number (MSISDN) is a telephone number uniquely identifying a subscriber across multiple mobile networks. The MSISDN is associated with a country code and a national destination code identifying the subscriber's operator.

You can configure a NetScaler appliance to include MSISDNs in LSN log entries for subscribers in mobile networks. The presence of MSISDNs in the LSN logs helps the administrator in faster and accurate back tracing of a mobile subscriber who has violated a policy or law, or whose information is required by lawful interception agencies.

The following sample LSN log entries include MSISDN information for a connection from a mobile subscriber in an LSN configuration. The log entries show that a mobile subscriber whose MSISDN is E164:5556543210 was connected to destination IP:port 23.0.0.1:80 through the NAT IP:port 203.0.113.3:45195.

LOG ENTRY TYPE	SAMPLE LOG ENTRY

LOG ENTRY TYPE	SAMPLE LOG ENTRY
LSN mapping	Oct 14 15:40:30 10.102.37.77 10/14/2015:10:11:14 GMT 0-PPE-6 : default LSN LSN_ADDR_MAPPING 25013 0 : ADM CREATED E164:5556543210 Client IP:Port:TD 192.0.2.50:4649:0, NatIP:NatPort 203.0.113.3:45195, Destination IP:Port:TD 23.0.0.1:0:0, Protocol: TCP

Perform the following tasks for including MSISDN information in LSN logs

- **Create an LSN log profile**. An LSN log profile includes the log subscriber ID parameter, which specifies whether to or not to include the MSISDN information in the LSN logs of an LSN configuration. Enable the log subscriber ID parameter when creating the LSN log profile.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the created LSN log profile to an LSN group of an LSN configuration by setting the log profile name parameter to the created LSN log profile name. For instructions on configuring Large Scale NAT, see Configuration Steps for LSN.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename -logSubscriberID ( ENABLED | DISABLED )

show lsn logprofile
```

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn group
```

Sample Configuration:

In this example of LSN configuration, the LSN log profile has the log subscriber ID parameter enabled. The profile is bound to LSN group LSN-GROUP-9. MSISDN information is included in the LSN session and LSN mapping logs for connections from mobile subscribers (in the network 192.0.2.0/24).

```
add lsn logprofile  LOG-PROFILE-MSISDN-9   -logSubscriberID ENABLED

Done

add lsn client LSN-CLIENT-9

Done

bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-9

Done

bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4

Done

add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9

Done

bind lsn group  LSN-GROUP-9  -logprofilename LOG-PROFILE-MSISDN-9

Done
```

Displaying Current LSN Sessions

You can display the current LSN sessions for detecting any unwanted or inefficient LSN sessions on the NetScaler appliance. You can display all or some LSN sessions on the basis of selection parameters.

Note: When more than a million LSN sessions exist on the NetScaler appliance, Citrix recommends displaying selected LSN sessions instead of all by using the selection parameters.

Configuration Using the CLI

To display all LSN sessions by using the CLI

At the command prompt, type:

```
show lsn session
```

To display selective LSN sessions by using the CLI

At the command prompt, type:

```
show lsn session [-clientname <string>] [-network <ip_addr> [-netmask
<netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <port>]]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example

To display all LSN sessions existing on a NetScaler

```
> show lsn session
          SubscrIP             SubscrPort      SubscrTD              DstIP                        DstPort DstTD     NatIP NatPort Proto   Dir

Done
```

Configuration Using the Configuration Utility

To display all or selected LSN sessions by using the configuration utility

1. Navigate to System > Large Scale NAT > Sessions, and click the NAT44 tab.
2. For displaying LSN sessions on the basis of selection parameters, click Search.

Parameter Descriptions (of commands listed in the CLI procedure)

- show lsn session
  - clientname

    Name of the LSN Client entity. Maximum Length: 127

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- network

  IP address or network address of subscriber(s).

- netmask

  Subnet mask for the IP address specified by the network parameter.

  Default value: 255.255.255.255

- td

  Traffic domain ID of the LSN client entity.

  Default value: 0

  Minimum value: 0

  Maximum value: 4094

- natIP

  Mapped NAT IP address used in LSN sessions.

Displaying LSN Statistics

You can display statistics related to the LSN feature for evaluating the performance of the LSN feature or to troubleshoot problems. You can display a summary of statistics of the LSN feature or of a particular LSN group. The statistical counters reflect events since the NetScaler appliance was last restarted. All these counters are reset to 0 when the NetScaler appliance is restarted.

To display all LSN statistics by using the CLI

At the command prompt, type:

```
stat lsn
```

To display statistics for a specified LSN group by using the CLI

At the command prompt, type:

```
stat lsn group [<groupname>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example

```
> stat lsn

Large Scale NAT statistics

                                                Rate(/s)            Total

LSN TCP Received Packets                               0                40

LSN TCP Received Bytes                                 0              3026

LSN TCP Transmitted Packets                            0                40

```

Parameter Descriptions (of commands listed in the CLI procedure)

- stat lsn group
  - groupname

    Name of the LSN Group. Maximum Length: 127
  - detail

    Specifies detailed output (including more statistics). The output can be quite voluminous. Without this argument, the output will show only a summary.
  - fullValues

    Specifies that numbers and strings should be displayed in their full form. Without this option, long strings are shortened and large numbers are abbreviated.
  - ntimes

    The number of times, in intervals of seven seconds, the statistics should be displayed.

    Default value: 1
  - logFile

    The name of the log file to be used as input.
  - clearstats

    Clear the statsistics / counters

    Possible values: basic, full

Compact Logging

Logging LSN information is one of the important functions needed by ISPs to meet legal requirements and be able to identify the source of traffic at any given time. This eventually results in a huge volume of log data, requiring the ISPs to make large investments to maintain the logging infrastructure.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Compact logging is a technique for reducing the log size by using a notational change involving short codes for event and protocol names. For example, C for client, SC for session created, and T for TCP. Compact logging results in an average of 40 percent reduction in log size.

The following examples of NAT44 mapping creation log entries show the advantage of compact logging.

Default logging format	02/02/2016:01:13:01 GMT Informational 0-PPE-2 : default LSN LSN_ADDRPORT_MAPPING 85 0 : A&PDM CREATED ClientIP:Port:TD1.1.1.1:6500:0,NatIP:NatPort8.8.8.8:47902, DestinationIP:Port:TD2.2.2.2:80:0, Protocol: TCP
Compact logging format	02/02/2016:01:14:57 GMT Info 0-PE2:default LSN 87 0:A&PDMC|C-1.1.1.1:6500:0| N-8.8.8.9:51066|D-2.2.2.2:80:0|T

Configuration Steps

Perform the following tasks for logging LSN information in compact format:

- **Create an LSN log profile.** An LSN log profile includes the Log Compact parameter, which specifies whether to or not to log information in compact format for an LSN configuration.
- **Bind the LSN log profile to an LSN group of an LSN configuration.** Bind the created LSN log profile to an LSN group of an LSN configuration by setting the Log Profile Name parameter to the created LSN log profile name. All sessions and mappings for this LSN group are logged in compact format.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logCompact (ENABLED|DISABLED)

show lsn logprofile
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname> -logProfileName <lsnlogprofilename>

show lsn group
```

Sample configuration:

```
add lsn logprofile  LOG-PROFILE-COMPACT-9 -logCompact ENABLED

Done

add lsn client LSN-CLIENT-9

Done

bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-9

Done

bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4

Done

add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9

Done

bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group  LSN-GROUP-9 –logProfileName LOG-PROFILE-COMPACT-9

Done
```

IPFIX Logging

The NetScaler appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following large scale NAT44 related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.
- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the NetScaler appliance. For instructions, see Configuring the AppFlow feature topic.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow® configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging ( ENABLED | DISABLED )

show appflow param
```

To create an LSN log profile by using the CLI

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )

show lsn logprofile
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.
2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

TCP SYN Idle Timeout

SYN idle timeout is the timeout for establishing TCP connections that use LSN on the NetScaler appliance. If a TCP session is not established within the configured timeout period, the NetScaler removes the session. SYN idle timeout is useful in providing protection against SYN flood attacks. In an LSN configuration, the LSN group entity includes the SYN idle timeout setting.

Example:

In the following sample LSN configuration, SYN idle timeout is set to 30 secs for TCP connections related to subscribers from the 192.0.2.0/24 network.

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 203.0.113.3

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1 –synidletimeout 30

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done
```

Overriding LSN configuration with Load Balancing Configuration

An LSN configuration takes precedence over any load balancing configuration by default. For overriding the large scale networking (LSN) configuration with the load balancing configuration for traffic matching both configurations, create a net profile with Override LSN parameter enabled and bind this profile to the virtual server of the load balancing configuration. USNIP or USIP settings of the load balancing configuration are applied to the traffic, instead of applying the LSN IP address of the LSN configuration.

This option is useful in an LSN deployment that includes NetScaler appliances and value added services, such as firewall and optimization devices. In this type of deployment, the ingress traffic on the NetScaler appliance is required to pass through these value-added services before an LSN configuration on the appliance is applied to the traffic. For the NetScaler appliance to send the ingress traffic to a value added service, a load balancing configuration is created and override LSN is enabled on the appliance. The load balancing configuration includes value added services, represented as load balancing services, bound to a virtual server of type ANY. The virtual server is configured with listen policies for identifying the traffic to be sent to the value added service.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable override lsn in a net profile by using the CLI

To enable override lsn while adding a net profile, at the command prompt, type

```
add netProfile <name> -overrideLsn ( ENABLED | DISABLED )

show netprofile <name>
```

To enable override lsn while adding a net profile, at the command prompt, type

```
set netProfile <name> -overrideLsn ( ENABLED | DISABLED )

show netprofile <name>
```

To enable override lsn in a net profile by using GUI

1. Navigate to **System** > **Network** > **Net Profiles**.
2. Set the **Override LSN** parameter while adding or modifying net profiles.

In the following sample configuration, net profile NETPROFILE-OVERRIDELSN-1 has override LSN option enabled and is bound to load balancing virtual server LBVS-1.

Sample configuration:

```
add netprofile NETPROFILE-OVERRIDELSN-1 -overrideLsn ENABLED

Done

set lb vserver LBVS-1 -netprofile NETPROFILE-OVERRIDELSN-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Clearing LSN Sessions

You can remove any unwanted or inefficient LSN sessions from the NetScaler appliance. The appliance immediately releases resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected LSN sessions from the NetScaler appliance.

To clear all LSN sessions by using the command line interface

At the command prompt, type:

```
flush lsn session

show lsn session
```

To clear selective LSN sessions by using the command line interface

At the command prompt, type:

```
flush lsn session [-clientname <string>] [-network <ip_addr> [-netmask
<netmask>] [-td <positive_integer>]] [-natIP <ip_addr> [-natPort <port>]]

show lsn session
```

Example

Clear all LSN sessions existing on a NetScaler

```
flush lsn session
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Clear all LSN sessions related to LSN client entity LSN-CLIENT-1

```
flush lsn session -clientname LSN-CLIENT-1

Done
```

Clear all LSN sessions related to a subscriber network (192.0.2.0) of LSN client entity LSN-CLIENT-2 belonging to traffic domain 100

```
flush lsn session -clientname LSN-CLIENT-2 –network 192.0.2.0 –netmask
255.255.255.0 –td 100

Done
```

To clear all LSN sessions by using the configuration utility

Navigate to System > Large Scale NAT > Sessions, and click Flush Sessions.

Parameter Descriptions (of commands listed in the CLI procedure)

- flush lsn session
  - clientname

    Name of the LSN Client entity. Maximum Length: 127
  - network

    IP address or network address of subscriber(s).
  - netmask

    Subnet mask for the IP address specified by the network parameter.

    Default value: 255.255.255.255
  - td

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Traffic domain ID of the LSN client entity.

Default value: 0

Minimum value: 0

Maximum value: 4094

- natIP

  Mapped NAT IP address used in LSN sessions.

- natPort

  Mapped NAT port used in the LSN sessions.

Load Balancing SYSLOG Servers

The NetScaler appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the NetScaler appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

```
add service <name>(<IP> | <serverName>) <serviceType (SYSLOGTCP |
SYSLOGUDP)> <port>
```

Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

```
add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod
<AUDITLOGHASH>]
```

Bind the service to the load balancing virtual server.

```
bind lb vserver <name> <serviceName>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

```
add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel
<logLevel>]
```

Add a SYSLOG policy by specifying the rule and action.

```
add syslogpolicy <name> <rule> <action>
```

Bind the SYSLOG policy to the system global for the policy to take effect.

```
bind system global <policyName>
```

Load balancing of SYSLOG servers using the configuration utility

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.

   Navigate to Traffic Management > Services, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.

   Navigate to Traffic Management > Virtual Servers, click Add and select SYLOGTCP or SYSLOGUDP as protocol.

3. Bing the service to the load balancing virtual server to the service.

   Bing the service to the load balancing virtual server.

   Navigate to Traffic Management > Virtual Servers, select a virtual server and then selectAUDITLOGHASH in the Load Balancing Method.

4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.

   Navigate to System > Auditing, click Servers and add a server by selecting LB Vserver option inServers.

5. Add a SYSLOG policy by specifying the rule and action.

   Navigate to System > Syslog, click Policies and add a SYSLOG policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Bind the SYSLOG policy to the system global for the policy to take effect.

   Navigate to System > Syslog, select a SYSLOG policy and click Action, and then click Global Bindings and bind the policy to system global.

Example:

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. The NetScaler appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514

add service service2 192.0.2.11 SYSLOGUDP 514

add service service3 192.0.2.11 SYSLOGUDP 514

add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH

bind lb vserver lbvserver1 service1

bind lb vserver lbvserver1 service2

bind lb vserver lbvserver1 service3

add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add syslogpolicy syspol1 ns_true sysaction1

bind system global syspol1
```

Limitations:

The NetScaler appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

Port Control Protocol

NetScaler appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by enabling the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP’s access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A NetScaler appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- (Optional) Create a PCP profile. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server

© 1997–2026 Citrix Systems, Inc. All rights reserved.

overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:

- Mapping: Enabled
- Peer: Enabled
- Minimum map life: 120 seconds
- Maximum max life: 86400 seconds
- Announce count: 10
- Third Party: Disabled

- Create a PCP server and bind a PCP profile to it. Create a PCP server on the NetScaler appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- Bind the PCP server to an LSN group of an LSN configuration. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group.

NOTE

A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

```
add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer ( ENABLED
| DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
announceMultiCount <positive_integer>][-thirdParty ( ENABLED | DISABLED )]

show pcp profile <name>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create a PCP server by using the CLI

At the command prompt, type:

```
add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile
<string>]

show pcp server <name>
```

Sample Configuration for NAT44

In the following sample configuration, PCP server PCP-SERVER-9, with default PCP settings, is bound to LSN group LSN-GROUP-9. PCP-SERVER-9 serves PCP requests from subscribers in network 192.0.2.0/24.

Sample configuration:

```
add pcp server PCP-SERVER-9 192.0.3.9

Done

add lsn client LSN-CLIENT-9

Done

bind lsn client LSN-CLIENT-9 -network 192.0.2.0 -netmask 255.255.255.0

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn pool LSN-POOL-9

Done

bind lsn pool LSN-POOL-9 203.0.113.3-203.0.113.4

Done

add lsn group LSN-GROUP-9 -clientname LSN-CLIENT-9

Done

bind lsn group LSN-GROUP-9 -poolname LSN-POOL-9

Done

bind lsn group  LSN-GROUP-9  -pcpServer PCP-SERVER-9

Done
```

LSN44 in a cluster setup

Large scale NAT44 configurations are supported on a NetScaler cluster setup.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

A NetScaler cluster is a group of NetScaler appliances that are configured and managed as a single system. A NetScaler cluster provides scalability and availability. Each NetScaler appliance in a cluster setup acts as an independent LSN entity and is managed as a single system.

The LSN configuration in a cluster setup is same as in a standalone appliance except a specific pool of LSN IP addresses are owned by only one node at a time. In other words, an LSN IP pool entity is configured as a spotted entity in a particular node. All the nodes of a cluster setup can have a specific LSN IP pool entity. To make sure that the packets related to an LSN session are received on the same cluster node that performed the NAT operation, policy based backplane (PBS) steering is configured. PBS steers the received related packets of an LSN session to the same cluster node.

Sample configuration:

```
add lsn client LSN-CLIENT-1

Done

bind lsn client LSN-CLIENT-1 -network 192.0.2.0 -netmask 255.255.255.0

Done

add lsn pool LSN-POOL-1

Done

bind lsn pool LSN-POOL-1 -ownerNode 1 203.0.113.3

```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn pool LSN-POOL-1 -ownerNode 2 203.0.113.3

Done

add lsn group LSN-GROUP-1 -clientname LSN-CLIENT-1

Done

bind lsn group LSN-GROUP-1 -poolname pool1 LSN-POOL-1

Done

add ns acl b1 ALLOW -srcIP = 192.0.2.0-192.0.2.255 -type DFD -dfdhash SIP

Done

apply ns acls -type DFD
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Dual-Stack Lite

NOTE:

Dual-Stack Lite feature is deprecated from NetScaler 14.1 release onwards.

Deprecated features are not removed immediately. The NetScaler® appliance continues to support the deprecated feature until it is removed in a future release.
Because of the shortage of IPv4 addresses, and the advantages of IPv6 over IPv4, many ISPs have started transitioning to IPv6 infrastructure. But during the transition, ISPs must continue to support IPv4 along with IPv6, because most of the public Internet still uses only IPv4, and many subscribers do not support IPv6.

Dual Stack Lite (DS-Lite) is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv4 subscribers to the Internet. DS-Lite uses IPv4-in-IPv6 tunneling to send a subscriber's IPv4 packet through a tunnel on the IPv6 access network to the ISP. The IPv6 packet is decapsulated to recover the subscriber's IPv4 packet and is then sent to the Internet after NAT address and port translation and other LSN related processing. The response packets traverse through the same path to the subscriber.

The NetScaler appliance implements the AFTR component of a DS-Lite deployment and is compliant with RFC 6333.

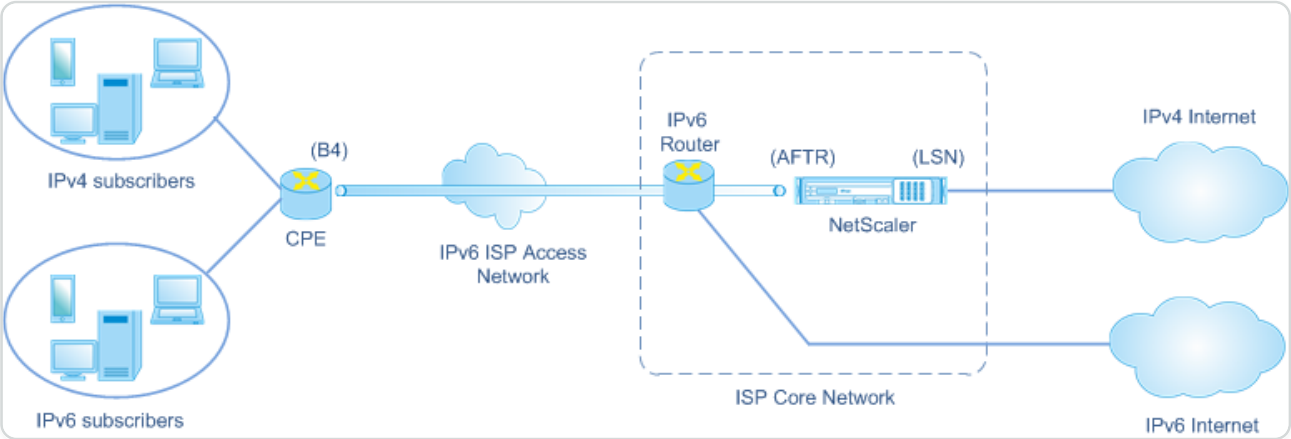
Architecture

The Dual-Stack Lite architecture for an ISP consists of the following components:

- **Basic Bridging Broadband (B4).** Basic Bridging broadband, or B4, is a device or component that resides in the subscriber premises. Typically, B4 is a component in the CPE devices in the subscriber premises. IPv4 subscribers are connected to the IPv6-only ISP access network through the CPE device containing the B4 component. The main function of the B4 is to initiate an IPv6 tunnel between B4 and an address family transition router (AFTR) in order to send or receive subscriber IPv4 request or response packets over the tunnel. B4 includes an IPv6 address known as the B4 tunnel endpoint address. B4 uses this address to source IPv6 packets to AFTR and receive packets from AFTR.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Address family transition router (AFTR).** AFTR is a device or component residing in the ISP's core network. AFTR terminates the IPv6 tunnel from the B4 device. In other words, the IPv6 tunnel is formed between B4 in the subscriber premise and AFTR in ISP core network. AFTR decapsulates IPv6 packets received from B4 to recover the subscribers' original IPv4 packets. AFTR sends the IPv4 packets to the LSN device or component. LSN routes the IPv4 packets to their destination after performing NAT address and port translation (NAT 44) and other LSN related processing. AFTR includes an IPv6 address known as the AFTR tunnel endpoint address. AFTR uses this address to source IPv6 packets to B4 and receive IPv6 packets from B4. The NetScaler appliance implements the AFTR component.
- **Softwire.** The IPv6 tunnel created between B4 and AFTR is called a softwire.



The DS-Lite architecture of an ISP using a NetScaler appliance consists of subscribers in private address spaces accessing the Internet through a NetScaler appliance deployed in ISP's core network. IPv4 subscribers are connected to a CPE device that includes the DS-Lite B4 functionality. The CPE device is connected to the ISP core network through ISP's IPv6-only access network. The NetScaler appliance contains the DS-Lite AFTR and LSN functionality.

IPv4 subscribers connected to the CPE device are assigned private IPv4 addresses either manually or through DHCP server running on the CPE device. On the CPE device, the AFTR tunnel endpoint address is specified manually or through DHCPv6. Configuration of CPE devices is vendor specific and therefore outside the scope of this documentation.

Upon receiving a request packet that is from an IPv4 subscriber and destined to a location on the Internet, the B4 component of the CPE device encapsulates the IPv4 packet in an IPv6 packet and sends it to the NetScaler appliance in the ISP core network. The NetScaler appliance's AFTR functionality decapsulates the IPv6 packet to recover the subscriber's original IPv4 packet. The LSN functionality of the NetScaler appliance translates the source IP address and port of the IPv4 packet to an NAT IP address and NAT port selected from the configured NAT pool, and then sends the packet to its destination on the Internet.

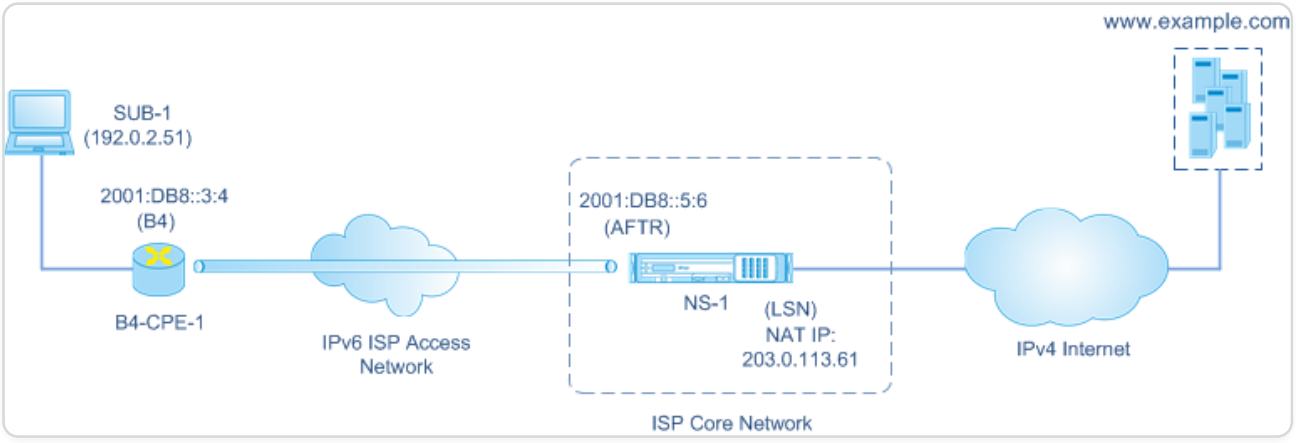
© 1997–2026 Citrix Systems, Inc. All rights reserved.

The appliance maintains a record of all active sessions that use the AFTR and LSN functionalities. These sessions are called DS-Lite sessions. The NetScaler appliance also maintains the mappings between B4 IPv6 address, subscriber IPv4 address and port, and NAT IPv4 address and port, for each DS-Lite session. These mappings are called DS-Lite LSN mappings. From DS-Lite session entries and DS-Lite LSN mapping entries, the NetScaler appliance recognizes a response packet (received from the Internet) as belonging to a particular DS-Lite session.

When the NetScaler appliance receives a response packet belonging to a particular DS-Lite session, the appliance's LSN functionality translates the destination IP address and port of the response packet from NAT IP address and port to the subscriber IP address and port, the AFTR functionality encapsulates the resulting packet in an IPv6 packet and sends it to the CPE device. The B4 functionality of the CPE device decapsulates the IPv6 packet to recover the IPv4 response packet, and then sends the IPv4 packet to the subscriber.

Example

Consider an example of a DS-Lite deployment consisting of NetScaler NS-1 in an ISP's core network, CPE device B4-CPE-1 in a subscriber premise, and a single IPv4 subscriber SUB-1. B4-CPE-1 supports the B4 functionality of DS-Lite feature.



The following table lists the settings used in this example.

ENTITY	NAME	DETAILS
IPv4 address of subscriber SUB-1	192.0.2.51	
IPv6 address of softwire endpoint on the B4 device (B4-CPE-1)	2001:DB8::3:4	

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ENTITY	NAME	DETAILS
IPv6 address of the softwire endpoint on the AFTR device (NS-1)	2001:DB8::5:6	

Settings on NetScaler appliance NS-1:

ENTITY	NAME	DETAILS
LSN client	LSN-DSLITE-CLIENT-1	Network6 (Identifying traffic from B4 devices) = 2001:DB8::3:0/100
LSN pool	LSN-DSLITE-POOL-1	LSN IPs (NAT IP) = 203.0.113.61 - 203.0.113.70
IPv6 Profile	LSN-DSLITE-PROFILE-1	Type = DS-LITE; IPv6 address (AFTR IPv6 address) = One of the NetScaler owned IPv6 address of type SNIP6 = 2001:DB8::5:6
LSN group	LSN-DSLITE-GROUP-1	LSN client = LSN-DSLITE-CLIENT-1; LSN pool = LSN-DSLITE-POOL-1;IPv6 profile = LSN-DSLITE-PROFILE-1

Following is the traffic flow in this example:

1. IPv4 subscriber SUB-1 sends a request to (`http://www.example.com/`). The IPv4 packet has:
   - Source IP address = 192.0.2.51
   - Source port = 2552
   - Destination IP address = 198.51.100.250
   - Destination port = 80
2. Upon receiving the IPv4 request packet, B4-CPE-1 encapsulates it in the payload of an IPv6 packet and then sends the IPv6 packet to NS-1. The IPv6 packet has:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Source IP address = 2001:DB8::3:4
- Destination IP address = 2001:DB8::5:6

3. When NS-1 receives the IPv6 packet, the AFTR module decapsulates the packet by removing the IPv6 headers. The resulting packet is SUB-1's original IPv4 request packet.
4. The LSN module of NS-1 translates the source IP address and port of the packet to an NAT IP address and NAT port selected from the configured NAT pool. The translated IPv4 packet has:
   - Source IP address = 203.0.113.61
   - Source port = 3002
   - Destination IP address = 198.51.100.250
   - Destination port = 80
5. The LSN module also creates an LSN mapping and session entry for this DS Lite session. The mapping includes the following information:
   - Source IP address of the IPv6 packet (B4-CPE-1's IPv6 address) = 2001:DB8::3:4
   - Source IP address of the IPv4 packet (SUB-1's IPv4 address) = 192.0.2.51
   - Source port of the IPv4 packet = 2552
   - NAT IP address = 203.0.113.61
   - NAT port = 3002
6. NS-1 sends the resulting IPv4 packet to its destination on the Internet.
7. The server for www.example.com processes the request packet and sends a response packet. The IPv4 response packet has:
   - Source IP address = 198.51.100.250
   - Source port = 80
   - Destination IP address = 203.0.113.61
   - Destination port = 3002
8. Upon receiving the IPv4 packet, NS-1 examines the LSN mapping and session entries and finds that the IPv4 response packet belongs to a DS Lite session. The LSN module of NS-1 translates the destination IP address and port. The IPv4 packet now has:
   - Source IP address = 198.51.100.250
   - Source port = 80

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Destination IP address = 192.0.2.51
- Destination port = 2552

9. The AFTR module of NS-1 encapsulates the IPv4 packet in an IPv6 packet and then sends the IPv6 packet to B4-CPE-1. The IPv6 packet has:
   - Source IP address = 2001:DB8::5:6
   - Destination IP address = 2001:DB8::3:4
10. Upon receiving the packet, B4-CPE-1 decapsualtes the IPv6 packet by removing the IPv6 headers, and then sends the resulting IPv4 packet to CL-1.

Points to Consider before Configuring DS-Lite

Consider the following points before configuring DS-Lite on a NetScaler appliance:

1. You must understand the different components of DS-Lite, described in RFC 6333.
2. A DS-lite configuration on a NetScaler appliance uses the LSN commands sets. In a DS-Lite configuration, the LSN client entity specifies the IPv6 address or IPv6 network address or ACL6 rules for identifying the traffic from the B4 device. A DS-Lite configuration also includes an IPv6 profile, which specifies the IPv6 address AFTR component on a NetScaler appliance. For more information on NetScaler LSN feature, see Large Scale NAT.
3. For a DS-Lite configuration, the NetScaler appliance supports LSN for IPv4 packets that belong to one of the following protocols only. The NetScaler appliance drops IPv4 packets belonging to other protocols:
   - TCP
   - UDP
   - ICMP
4. The NetScaler appliance supports the following ALGs DS-Lite:
   - ICMP
   - FTP
   - TFTP
   - Session Initiation Protocol (SIP)
   - Real Time Streaming Protocol (RTSP)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring DS-Lite

A DS-lite configuration on a NetScaler appliance uses the LSN commands sets. In a DS-Lite configuration, the LSN client entity specifies the IPv6 address or IPv6 network address or ACL6 rules for identifying the traffic from the B4 device. For more information on the NetScaler LSN feature, see Large Scale NAT. A DS-Lite configuration also includes an IPv6 profile, which specifies the IPv6 address (of type SNIP6) of the DS-Lite AFTR component on a NetScaler appliance.

Configuring DS-Lite on a NetScaler appliance consists of the following tasks:

- **Set the global LSN parameters**. Global parameters include the amount of NetScaler memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
- **Create an LSN client entity for identifying traffic from B4 CPE devices**. The LSN client entity refers to a set of DS-Lite B4 devices. The client entity includes IPv6 addresses or IPv6 network address or ACL6 rules for identifying the traffic from these B4 devices. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The configuration utility combines these two operations on a single screen.
- **Create an LSN pool and bind NAT IP addresses to it**. An LSN pool defines a pool of NAT IP addresses to be used by the NetScaler appliance to perform LSN. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The configuration utility combines these two operations on a single screen.
- **Create an LSN IP6 profile.** An LSN IP6 profile defines the IPv6 address of the DS-Lite AFTR component on the NetScaler appliance. The IPv6 address must be one of the NetScaler owned IPv6 address of type SNIP6.
- **(Optional) Create an LSN Transport Profile for a specified protocol**. An LSN transport profile defines various timeouts and limits, such as maximum LSN sessions and maximum ports usage that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called the default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
- **(Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it**. An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN

© 1997–2026 Citrix Systems, Inc. All rights reserved.

group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The configuration utility combines these two operations on a single screen.

- **Create an LSN Group and bind LSN pools, LSN IPv6 profile, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group**. An LSN group is an entity consisting of an LSN client, an LSN IPv6 profile, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only one LSN IPv6 profile can be bound to an LSN group, and an LSN IPv6 profile bound to an LSN group cannot be bound to other LSN groups. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, and LSN application profiles to the LSN group. The configuration utility combines these two operations in a single screen.

Configuration by Using the Command Line

To create an LSN client by using the command line interface:

At the command prompt, type:

```
add lsn client <clientname>

show lsn client
```

To bind an IPv6 network or an ACL6 rule to an LSN client by using the command line interface:

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn client <clientname> (-network6 <ipv6_addr|*>| -acl6name <string>)

show lsn client
```

To create an LSN pool by using the command line interface:

At the command prompt, type:

```
add lsn pool <poolname> [-nattype ( DYNAMIC )] [-portblockallocation
( ENABLED | DISABLED )] [-portrealloctimeout <secs>] [-maxPortReallocTmq
<positive_integer>]

show lsn pool
```

To bind an IP address range to an LSN pool by using the command line interface:

At the command prompt, type:

```
bind lsn pool <poolname> <lsnip>

show lsn pool
```

Note: For removing LSN IP addresses from an LSN pool, use the unbind lsn pool command.

To configure an LSN IPv6 profile by using the command line interface:

At the command prompt, type:

```
add lsn ip6profile <name> –type DS-Lite –network6 < ipv6_addr|*s >

show lsn ip6profile
```

To create an LSN transport profile by using the command line interface:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

At the command prompt, type:

```
add lsn transportprofile <transportprofilename> <transportprotocol> [-
sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota
<positive_integer>] [-sessionquota <positive_integer>] [-
portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (ENABLED |
DISABLED )] [-syncheck ( ENABLED | DISABLED )]

show lsn transportprofile
```

To create an LSN application profile by using the command line interface:

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling
(PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
tcpproxy ( ENABLED | DISABLED )] [-td <positive_integer>]

show lsn appsprofile
```

To bind an application protocol port range to an LSN application profile by using the command line interface:

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
```

To create an LSN group by using the command line interface:

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC )] [-
portblocksize <positive_integer>] [-logging (ENABLED | DISABLED )] [-
sessionLogging ( ENABLED | DISABLED )][-sessionSync ( ENABLED |
DISABLED )] [-snmptraplimit<positive_integer>] [-ftp ( ENABLED |
DISABLED )] [-pptp ( ENABLED |DISABLED )] [-sipalg ( ENABLED | DISABLED )]
[-rtspalg ( ENABLED |DISABLED )] [-ip6profile <string>]

show lsn group
```

To bind LSN protocol profiles and LSN pools to an LSN group by using the command line interface:

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
<string> | -httphdrlogprofilename <string> | -appsprofilename <string> |
-sipalgprofilename <string> | rtspalgprofilename <string>)

show lsn group
```

Configuration by Using the Configuration Utility

To configure an LSN client and bind an IPv6 network address or an ACL6 rule by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Clients**, and add a client and then bind an IPv6 network address or an ACL6 rule to the client.

To configure an LSN pool and bind NAT IP addresses by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Pools**, and add a pool and then bind an NAT IP address or a range of NAT IP addresses to the pool.

To configure an LSN IPv6 profile by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Profiles**, click the **IPv6** tab, and assign an IPv6 address for DS-Lite AFTR.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure an LSN transport profile by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Profiles**.
2. On the details pane, click **Transport**, and then add a transport profile.

To configure an LSN application profile by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Profiles**.
2. On the details pane, click **Application**, and then add an application profile.

To configure an LSN group and bind an LSN client, an LSN IPv6 profile, pools, transport profiles, and application profiles by using the configuration utility:

Navigate to **System** > **Large Scale NAT** > **Groups**, and add a group and then bind an LSN client, an LSN IPv6 profile, pools, transport profiles, and application profiles to the group.

```
> add lsn client LSN-DSLITE-CLIENT-1

Done

> bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100

Done

> add lsn pool LSN-DSLITE-POOL-1

Done

> bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70

Done

> add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6
2001:DB8::5:6

Done

> add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1
-portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1

Done

> add lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Logging and Monitoring DS-Lite

You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The NetScaler appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a NetScaler appliance whose NSIP address is 10.102.37.115.You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The NetScaler appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

Displaying Current DS-Lite Sessions

You can display the current DS-Lite sessions for detecting any unwanted or inefficient sessions on the NetScaler appliance. You can display all or some DS-Lite sessions, on the basis of selection parameters.

Configuration by Using the Command Line Interface

To display all DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
show lsn session –nattype DS-Lite
```

To display selected DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
show lsn session –nattype DS-Lite [-clientname <string>] [-network
<ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr>
[-natPort <port>]]
```

Example:

The following sample ouput displays all DS-Lite sessions existing on a NetScaler appliance:

```
show lsn session –nattype DS-Lite

  B4-Address SubscrIP SubscrPort SubscrTD DstIP DstPort DstTD NatIP
NatPort Proto Dir
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
1.  2001:DB8::3:4 192.0.2.51 2552 0 198.51.100.250 80 0 203.0.113.61 3002
TCP OUT

2.  2001:DB8::3:4 192.0.2.51 3551 0 198.51.100.300 80 0 203.0.113.61 52862
TCP OUT

3.  2001:DB8::3:4 192.0.2.100 4556 0 198.51.100.250 0 0 203.0.113.61 48116
ICMP OUT

4.  2001: DB8::190 192.0.2.150 3881 0 198.51.100.199 80 0 203.0.113.69
48305 TCP OUT

Done
```

Configuration Using the Configuration Utility

To display all or selected DS-Lite sessions by using the configuration utility

1. **Navigate to System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. For displaying DS-Lite sessions on the basis of selection parameters, click **Search**.

Clearing DS-Lite Sessions

You can remove any unwanted or inefficient DS-Lite sessions from the NetScaler appliance. The appliance immediately releases the resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected DS-Lite sessions from the NetScaler appliance.

To clear all DS-Lite sessions by using the command line interface:

At the command prompt, type:

`flush lsn session –nattype DS-Lite` `show lsn session –nattype DS-Lite`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To clear selected DS-Lite sessions by using the command line interface:

At the command prompt, type:

```
flush lsn session –nattype DS-Lite [-clientname <string>] [-network
<ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr>
[-natPort <port>]]

show lsn session –nattype DS-Lite
```

To clear all or selected DS-Lite sessions by using the configuration utility:

1. Navigate to **System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. Click **Flush Sessions**.

Configuring DS-Lite Static Maps

The NetScaler appliance supports manual creation of DS-Lite LSN mappings, which contain the mapping between the following information:

- Subscriber's IP address and port, and IPv6 address of B4 device or component
- NAT IP address and port

Static DS-Lite LSN mappings are useful in cases where you want to ensure that the connections initiated to a NAT IP address and port map to the subscriber IP address and port through the specified B4 device (for example, web servers located in the internal network).

Note: This feature is supported in release 11.0 build 64.x and later.

To create a DS-Lite static LSN mapping by using the command line

At the command prompt, type:

```
add lsn static <name> <transportprotocol> <subscrIP> <subscrPort> [-td
<positive_integer>] [-network6 <B4_ADDR>] [<natIP> [<natPort>]] [-
destIP<ip_addr> [-dsttd <positive_integer>]]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn static
```

Parameter Descriptions

add lsn static

- name

Name for the LSN static mapping entry. Must begin with an ASCII alphanumeric or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the LSN group is created. The following requirement applies only to the CLI: If the name includes one or more spaces, enclose the name in double or single quotation marks (for example, "ds-lite lsn static1" or 'ds-lite lsn static1'). This is a mandatory argument. Maximum Length: 127

- transportprotocol

Protocol for the DS-Lite LSN mapping entry.

- subscrIP

IPv4 address of a subscriber for the DS-Lite LSN mapping entry.

- subscrPort

Port of the subscriber for the DS-Lite LSN mapping entry.

- Network6

IPv6 address of the B4 device or component.

- td

ID of the traffic domain to which the B4 device belongs. The IPv6 address of the B4 device is specified in the network6 paramter. If you do not specify an ID, the B4 device is assumed to be a part of the default traffic domain.

- natIP

IPv4 address, already existing on the NetScaler appliance as type LSN, to be used as NAT IP address for this mapping entry.

- natPort

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NAT port for this DS-Lite LSN mapping entry.

- destIP

Destination IP address for the DS-Lite LSN mapping entry.

- dsttd

ID of the traffic domain through which the destination IP address for this DS-Lite LSN mapping entry is reachable from the NetScaler appliance. If you do not specify an ID, the destination IP address is assumed to be reachable through the default traffic domain, which has an ID of 0.

To create a DS-Lite static LSN mapping by using the configuration utility

Navigate to System > Large Scale NAT > Static, and add a new DS-Lite static LSN mapping.

Configuring Deterministic NAT Allocation for DS-Lite

Deterministic NAT allocation for DS-Lite LSN deployments is a type of NAT resource allocation in which the NetScaler appliance pre-allocates, from the LSN NAT IP pool and on the basis of the specified port block size, an LSN NAT IP address and a block of ports to each subscriber (subscriber behind B4 device).

Note: This feature is supported in release 11.0 build 64.x and later.

The appliance sequentially allocates NAT resources to these subscribers. It assigns the first block of ports on the beginning NAT IP address to the beginning subscriber IP address. The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT address is assigned to the subscriber, and so on.

The NetScaler appliance logs the allocated NAT IP address and the port block for a subscriber. For a connection, a subscriber can be identified by just its mapped NAT IP address and port block. For this reason, the NetScaler appliance does not log the creation or deletion of an LSN session.

A DS-Lite subscriber can have only one deterministic port block. If the entire block of ports is being used, the NetScaler appliance drops any new connection from the subscriber.

Example: Deterministic DS-Lite

In this example, a deterministic DS-Lite configuration includes four subscribers with IP addresses 192.0.17.5, 192.0.17.6, 192.0.17.7, and 192.0.17.8. These ipv4 subscribers are behind a B4

© 1997–2026 Citrix Systems, Inc. All rights reserved.

device having the IPv6 address 2001:DB8::3:4. In this configuration, the port block size is set to 20480 and LSN NAT IP address pool has IP addresses in the range 203.0.113.41-203.0.113.42.

The NetScaler appliance sequentially pre-allocates, from the LSN NAT IP pool and on the basis of the set port block size, an LSN NAT IP address and a block of ports to each subscriber. It assigns the first block of ports (1024-21503) on the beginning NAT IP address (203.0.113.41) to the beginning subscriber IP address (192.0.17.5). The next range of ports is assigned to the next subscriber, and so on, until the NAT address does not have enough ports for the next subscriber. At that point, the first port block on the next NAT IP address is assigned to the subscriber, and so on. The NetScaler logs the NAT IP address and the block of ports allocated for each subscriber.

The NetScaler appliance does not log any LSN session created or deleted for these subscribers.

The following table lists the NAT IP address and blocks of ports allocated to each subscriber in this example:

Subscriber IP address	Allocated NAT IP address	Allocated Block of Ports	IPv6 address of B4
192.0.17.5	203.0.113.41	1024 - 21503	2001:DB8::3:4
192.0.17.6	203.0.113.41	21504 - 41983	2001:DB8::3:4
192.0.17.7	203.0.113.41	41984 - 62463	2001:DB8::3:4
192.0.17.8	203.0.113.42	1024 - 21503	2001:DB8::3:4

Configuration Steps

You need to configure deterministic NAT as part of the DS-Lite configuration. For instructions on configuring DS-Lite, see Configuring DS-Lite.

While configuring DS-Lite, make sure that you:

- Set the NAT Type parameter to Deterministic when adding the LSN pool and the LSN group.
- Set the desired port block size parameter when adding the LSN group, unless you can accept the default value.

Points to Consider before Configuring Deterministic DS-Lite

Consider the following points before configuring deterministic DS-Lite:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- The complete IP address of each subscriber must be specified in a separate add lsn client command, by setting the Network and Netmask parameters. (Set Netmask to 255.255.255.255.) Also the IPv4 address of the B4 device specified in Network6 parameter must be complete (/128 prefix). In other words, Network and Network6 parameter do not accept addresses other than /32 bit mask and /128 prefix, respectively.
- The NetScaler appliance drops connections from subscribers that are not specified in any deterministic DS-Lite configuration but are behind B4 devices specified in a deterministic DS-lite configuration.
- The NetScaler appliance recognizes subscribers having the same IPv4 address as different subscribers if they are behind different B4 devices. A combination of subscriber IPv4 address and B4 device defines a unique subscriber in the LSN client entity of a DS-Lite configuration.

Sample Deterministic DS-Lite Configuration:

The following configuration uses the settings listed in section Example: Deterministic DS-Lite.

```
add lsn client LSN-DSLITE-CLIENT-10

Done

bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.5 -netmask
255.255.255.255 -network6 2001:DB8::3:4/128

Done

bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.6 -netmask
255.255.255.255 -network6 2001:DB8::3:4/128

Done

bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.7 -netmask
255.255.255.255 -network6 2001:DB8::3:4/128
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn client LSN-DSLITE-CLIENT-10 -network 192.0.17.8 -netmask
255.255.255.255 -network6 2001:DB8::3:4/128

Done

add lsn pool LSN-DSLITE-POOL-10 -nattype DETERMINISTIC

Done

bind lsn pool LSN-DSLITE-POOL-10  203.0.113.41-203.0.113.42

Done

add lsn ip6profile LSN-DSLITE-PROFILE-10 -type DS-Lite -network6
2001:DB8::5:6

Done

add lsn group LSN-DSLITE-GROUP-10 -clientname LSN-DSLITE-CLIENT-10
-nattype DETERMINISTIC -portblocksize 20480 -ip6profile LSN-DSLITE-
PROFILE-10

Done

bind lsn group LSN-DSLITE-GROUP-10 -poolname LSN-DSLITE-POOL-10

Done
```

Configuring Application Layer Gateways for DS-Lite

For some application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet's payload. Application Layer Gateway (AGL) for a protocol parses the packet payload and does necessary changes to ensure that the protocol continues to work over DS-Lite.

The NetScaler appliance supports ALG for the following protocols for DS-Lite:

- FTP
- ICMP
- TFTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

You can enable or disable ALG for the FTP protocol for a DS-Lite configuration by enabling or disabling the FTP ALG option of the LSN group of the configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for a DS-Lite configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Application Layer Gateway for SIP Protocol

Using DS-Lite with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. SIP ALG for DS-Lite is compliant with RFC 3261, RFC 3581, RFC 4566, and RFC 4475.

NOTE

SIP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Limitations of SIP ALG

SIP ALG for DS-Lite has the following limitations:

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - Admin partitions
  - Multipart body
  - Line folding

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring DS-Lite. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Create a SIP ALG profile and make sure that you define either the source port range or destination port range. Bind the SIP ALG profile to the LSN group
- Enable SIP ALG in the LSN group

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string>[-sipalg ( ENABLED |
DISABLED )]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn group<groupname>
```

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn sipalgprofile<sipalgprofilename>[-
dataSessionIdleTimeout<positive_integer>][-
sipSessionTimeout<positive_integer>][-
registrationTimeout<positive_integer>][-sipsrcportrange<port[-port]>][-
sipdstportrange<port[-port]>][-openRegisterPinhole ( ENABLED | DISABLED )]
[-openContactPinhole ( ENABLED | DISABLED )][-openViaPinhole ( ENABLED |
DISABLED )][-openRecordRoutePinhole ( ENABLED | DISABLED )]-
sipTransportProtocol ( TCP | UDP )[-openRoutePinhole ( ENABLED |
DISABLED )][-rport ( ENABLED | DISABLED )]

show lsn sipalgprofile<sipalgprofilename>
```

Sample Configuration

The following sample DS-Lite configuration, SIP ALG is enabled for TCP traffic from B4 devices in the network 2001:DB8::3:0/96.

```
add lsn client LSN-DSLITE-CLIENT-1

Done

bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/96

Done

add lsn pool LSN-DSLITE-POOL-1

Done

bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6
2001:DB8::5:6

Done

add lsn appsprofile LSN-DSLITE-APPS-PROFILE-1 TCP -ippooling PAIRED –
mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn sipalgprofile SIPALGPROFILE-1  -sipdstportrange 5060
-sipTransportProtocol TCP

Done

add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1
-portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1 -sipalg ENABLED

Done

bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -appsprofilename LSN-DSLITE-APPS-
PROFILE-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -sipalgprofilename SIPALGPROFILE-1

Done
```

Application Layer Gateway for RTSP Protocol

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. NetScaler functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to NetScaler owned public IP address called LSN IP address.
- Inbound response—LSN IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

NOTE

RTSP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

Limitations of RTSP ALG

The RTSP ALG does not support the following:

- Multicast RTSP sessions
- RTSP session over UDP
- Admin partitions
- RTSP Authentication
- HTTP tunneling

Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring DS-Lite. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Enable RTSP ALG in the LSN group
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-rtspalg ( ENABLED |
DISABLED )]

show lsn group <groupname>
```

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn rtspalgprofile <rtspalgprofilename> [-rtspIdleTimeout
<positive_integer>] -rtspportrange <port[-port]> [-rtspTransportProtocol
(TCP|UDP)]

show lsn rtspalgprofile <rtspalgprofilename>
```

Sample RTSP ALG Configuration

The following sample DS-Lite configuration, RTSP ALG is enabled for TCP traffic from B4 devices in the network 2001:DB8::4:0/96.

Sample RTSP ALG Configuration:

```
add lsn client LSN-DSLITE-CLIENT-5

Done

bind lsn client LSN-DSLITE-CLIENT-5 -network6 2001:DB8::4:0/96

Done

add lsn pool LSN-DSLITE-POOL-5
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn pool LSN-DSLITE-POOL-5 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-DSLITE-PROFILE-5 -type DS-Lite -network6
2001:DB8::5:6

Done

add lsn appsprofile LSN-DSLITE-APPS-PROFILE-5 TCP -ippooling PAIRED –
mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn rtspalgprofile RTSPALGPROFILE-5 -rtspIdleTimeout 1000
-rtspportrange 554

Done

add lsn group LSN-DSLITE-GROUP-5 -clientname LSN-DSLITE-CLIENT-5
-portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-5 -rtspalg ENABLED

Done

bind lsn group LSN-DSLITE-GROUP-5 -poolname LSN-DSLITE-POOL-5

Done

bind lsn group LSN-DSLITE-GROUP-5 -appsprofilename LSN-DSLITE-APPS-
PROFILE-5

Done

bind lsn group LSN-DSLITE-GROUP-5 -rtspalgprofilename RTSPALGPROFILE-5

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Logging and Monitoring DS-Lite

You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The NetScaler appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a NetScaler appliance whose NSIP address is 10.102.37.115.You can log DS-Lite information to diagnose or troubleshoot problems, and to meet legal requirements. The NetScaler appliance supports all LSN logging features for logging DS-Lite information. For configuring DS-Lite logging, use the procedures for configuring LSN logging, described at Logging and Monitoring LSN.

A log message for a DS-Lite LSN mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (MAPPING)
- Whether the DS-Lite LSN mapping entry was created or deleted
- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for Endpoint-Independent mapping.
  - Only the destination IP address is logged for Address-Dependent mapping. The port is not logged.
  - Destination IP address and port are logged for Address-Port-Dependent mapping.

A log message for a DS-Lite session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)
- Whether the DS-Lite session is created or removed

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- IPv6 address of B4
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table shows sample DS-Lite log entries of each type stored on the configured log servers. These log entries are generated by a NetScaler appliance whose NSIP address is 10.102.37.115.

LSN Log Entry Type	Sample Log Entry
DS-Lite session creation	Local4.Informational 10.102.37.115 08/14/2015:13:35:38 GMT 0-PPE-1 : default LSN LSN_SESSION 37647607 0 : SESSION CREATED 2001:DB8::3:4 Client IP:Port:TD 192.0.2.51:2552:0, NatIP:NatPort 203.0.113.61:3002, Destination IP:Port:TD 198.51.100.250:80:0, Protocol:TCP

Displaying Current DS-Lite Sessions

You can display the current DS-Lite sessions for detecting any unwanted or inefficient sessions on the NetScaler appliance. You can display all or some DS-Lite sessions, on the basis of selection parameters.

To display all DS-Lite sessions by using the command line interface

At the command prompt, type:

```
show lsn session –nattype DS-Lite
```

To display selected DS-Lite sessions by using the command line interface

At the command prompt, type:

```
show lsn session –nattype DS-Lite [-clientname <string>] [-network
<ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr>
[-natPort <port>]]
```

The following sample ouput displays all DS-Lite sessions existing on a NetScaler appliance:

show lsn session –nattype DS-Lite

```
  B4-Address SubscrIP SubscrPort SubscrTD DstIP DstPort DstTD NatIP
NatPort Proto Dir

1. 2001:DB8::3:4 192.0.2.51 2552 0 198.51.100.250 80 0 203.0.113.61 3002
TCP OUT

2. 2001:DB8::3:4 192.0.2.51 3551 0 198.51.100.300 80 0 203.0.113.61 52862
TCP OUT
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
3. 2001:DB8::3:4 192.0.2.100 4556 0 198.51.100.250 0 0 203.0.113.61 48116
ICMP OUT

4. 2001: DB8::190 192.0.2.150 3881 0 198.51.100.199 80 0 203.0.113.69
48305 TCP OUT

Done
```

Configuration Using the Configuration Utility

To display all or selected DS-Lite sessions by using the configuration utility

1. **Navigate to System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. For displaying DS-Lite sessions on the basis of selection parameters, click **Search**.

Clearing DS-Lite Sessions

You can remove any unwanted or inefficient DS-Lite sessions from the NetScaler appliance. The appliance immediately releases the resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected DS-Lite sessions from the NetScaler appliance.

To clear all DS-Lite sessions by using the command line interface

At the command prompt, type:

```
flush lsn session –nattype DS-Lite

show lsn session –nattype DS-Lite
```

To clear selected DS-Lite sessions by using the command line interface

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
flush lsn session –nattype DS-Lite [-clientname <string>] [-network
<ip_addr> [-netmask <netmask>] [-td <positive_integer>]] [-natIP <ip_addr>
[-natPort <port>]]

show lsn session –nattype DS-Lite
```

To clear all or selected DS-Lite sessions by using the configuration utility

1. Navigate to **System** > **Large Scale NAT** > **Sessions**, and click the **DS-Lite** tab.
2. Click **Flush Sessions**.

Logging HTTP Header Information

The NetScaler appliance can log request header information of an HTTP connection that is using the DS-Lite functionality. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to
- HTTP Method specified in the HTTP request
- HTTP version used in the HTTP request
- IPv4 address of the subscriber that sent the HTTP request

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set of subscribers. For example, an ISP can use this feature to find out the most popular website among a set of subscribers.

Configuration Steps

Perform the following tasks for configuring the NetScaler appliance to log HTTP header information:

- **Create an HTTP header log profile**. An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging.
- **Bind the HTTP header to an LSN group of a DS-Lite LSN configuration**. Bind the HTTP header log profile to an LSN group of an LSN configuration by setting the HTTP header log

© 1997–2026 Citrix Systems, Inc. All rights reserved.

profile name parameter to the name of the created HTTP header log profile. The NetScaler appliance then logs HTTP header information of any HTTP requests related to the LSN group. An HTTP header log profile can be bound to multiple LSN groups, but an LSN group can have only one HTTP header log profile.

To create an HTTP header log profile by using the command line interface

At the command prompt, type:

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED |
DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion ( ENABLED |
DISABLED )] [-logHost ( ENABLED | DISABLED )]

show lsn httphdrlogprofile
```

To bind an HTTP header log profile to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
```

Sample Configuration

In the following DS-Lite LSN configuration, HTTP header log profile HTTP-Header-LOG-1 is bound to LSN group LSN-DSLITE-GROUP-1. The log profile has all the HTTP attributes (URL, HTTP method, HTTP version, and HOST IP address) enabled for logging, so that all these attributes are logged for any HTTP requests from B4 devices (in the network 2001:DB8:5001::/96).

Sample Configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1

Done

add lsn client LSN-DSLITE-CLIENT-1

Done

bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100

Done

add lsn pool LSN-DSLITE-POOL-1

Done

bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6
2001:DB8::5:6
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn group LSN-DSLITE-GROUP-1 -clientname LSN-DSLITE-CLIENT-1
-portblocksize 1024 -ip6profile LSN-DSLITE-PROFILE-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-DSLITE-POOL-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -httphdrlogprofilename HTTP-HEADER-LOG-1

Done
```

IPFIX Logging

The NetScaler appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following DS_Lite related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the NetScaler appliance. For instructions, see Configuring the AppFlow feature.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow® configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging (ENABLED |DISABLED )

show appflow param
```

To create an LSN log profile by using the CLIAt the command prompt, type

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn logprofile
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.
2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

Port Control Protocol for DS-Lite

NetScaler appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by

© 1997–2026 Citrix Systems, Inc. All rights reserved.

enabling the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP’s access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A NetScaler appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- (Optional) Create a PCP profile. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:
  - Mapping: Enabled
  - Peer: Enabled
  - Minimum map life: 120 seconds
  - Maximum max life: 86400 seconds
  - Announce count: 10
  - Third Party: Disabled
- Create a PCP server and bind a PCP profile to it. Create a PCP server on the NetScaler appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- Bind the PCP server to an LSN group of an LSN configuration. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group. Note: A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer ( ENABLED
| DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
announceMultiCount <positive_integer>][-thirdParty ( ENABLED | DISABLED )]

show pcp profile <name>
```

To create a PCP server by using the CLI

At the command prompt, type:

```
add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile
<string>]

show pcp server <name>
```

Sample Configuration for DS-LITE

In the following sample configuration, PCP server PCP-SERVER-1, with PCP settings from PCP-DSLITE-PROFILE-1, is bound to LSN group LSN-DSLITE-GROUP-1. PCP-SERVER-9 serves PCP requests from IPv4 subscribers behind B4 devices from network 2001:DB8::3:0/100.

Sample configuration:

```
add pcp profile PCP-DSLITE-PROFILE-1 -minMapLife 300

Done

add pcp server PCP-DSLITE-SERVER-1 192.0.3.10  -pcpProfile PCP-DSLITE-
PROFILE-1

Done

add lsn client LSN-DSLITE-CLIENT-1

Done

bind lsn client LSN-DSLITE-CLIENT-1 -network6 2001:DB8::3:0/100
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn pool LSN-DSLITE-POOL-1

Done

bind lsn pool LSN-DSLITE-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-DSLITE-PROFILE-1 -type DS-Lite -network6
2001:DB8::5:6

Done

add lsn group LSN-DSLITE-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -poolname LSN-NAT64-POOL-1

Done

bind lsn group LSN-DSLITE-GROUP-1 -poolname  PCP-NAT64-SERVER-1

Done
```

Large Scale NAT64

NOTE:

Large Scale NAT64 (LSN64) feature is deprecated from NetScaler 14.1 release onwards.

Deprecated features are not removed immediately. The NetScaler® appliance continues to support the deprecated feature until it is removed in a future release.

Because of the imminent exhaustion of IPv4 addresses, ISPs have started transitioning to IPv6 infrastructure. But during the transition, ISPs must continue to support IPv4 along with IPv6, because most of the public Internet still uses IPv4. Large scale NAT64 is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv6-only subscribers to the IPv4 Internet. DNS64

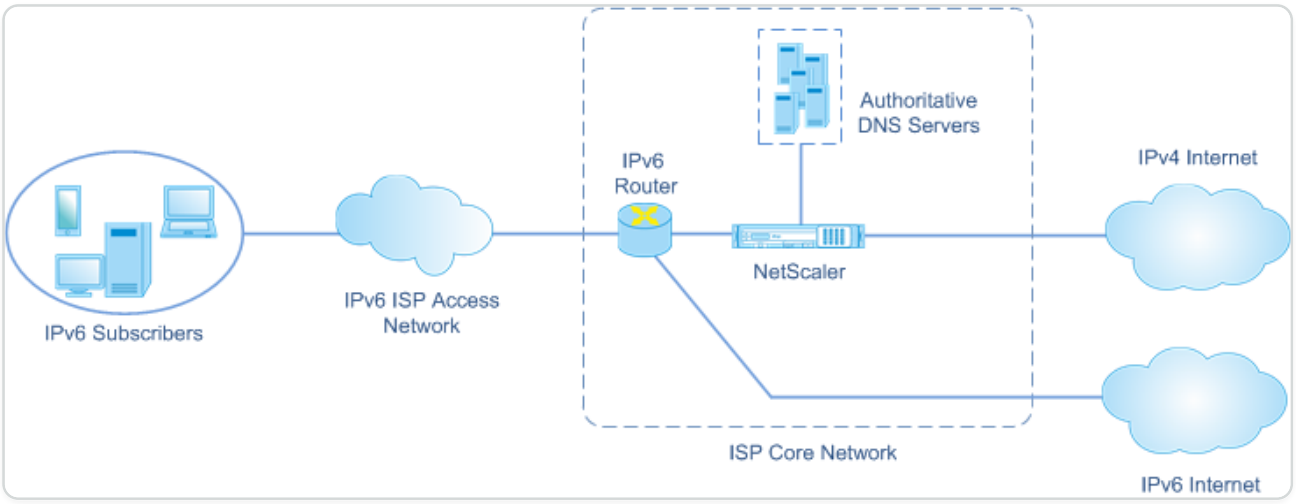
© 1997–2026 Citrix Systems, Inc. All rights reserved.

is a solution for enabling discovery of IPv4-only domains by IPv6-only clients. DNS64 is used with large scale NAT64 to enable seamless communication between IPv6-only clients and IPv4-only servers.

A NetScaler appliance implements large scale NAT64 and DNS64 and is compliant with RFCs 6145, 6146, 6147, 6052, 3022, 2373, 2765, and 2464.

Architecture

The NAT64 architecture of an ISP using a NetScaler appliance consists of IPv6 subscribers accessing the IPv4 Internet through a NetScaler appliance deployed in the ISP's core network. IPv6 subscribers are connected to the ISP core network through the ISP's IPv6-only access network.



The large scale NAT64 functionality of a NetScaler appliance enables communication between IPv6 clients and IPv4 servers through IPv6-to-IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance.NetScaler DNS64 functionality represents IPv4-only domains to IPv6-subscribers by synthesizing DNS AAAA records for IPv4-only domains and sending them to the subscribers.

Large scale NAT64 has two main components: NAT64 prefix and NAT IPv4 pool. DNS64 has one main component, DNS64 prefix, which has the same value as NAT64 prefix.

Upon receiving an AAAA request from an IPv6-only subscriber for a domain name that is hosted on an IPv4-only web server on the Internet, the NetScaler DNS64 functionality synthesizes an AAAA record for the domain name and sends it to the subscriber. The AAAA record is synthesized by concatenating the DNS64 prefix (which is set to the NAT64 prefix) and the actual IPv4 address of the domain name.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The subscriber now has an IPv6 destination address that corresponds to the desired domain name. The subscriber sends the request to the synthesized IPv6 address. Upon receiving the IPv6 request, the large scale NetScaler NAT64 functionality translates the IPv6 request packet to an IPv4 request packet. Large scale NAT64 sets the IPv4 request's destination address to the IPv4 address, which is extracted from the IPv6 request's destination address by stripping the NAT64 prefix from the IPv6 address. The destination port is retained from the IPv6 request. Large Scale NAT64 also sets the source IP address:source port of the IPv4 packet to the NAT IP address:NAT port selected from the configured NAT pool.

The appliance maintains a record of all active sessions that use the large scale NAT64 functionality. These sessions are called large scale NAT64 sessions. The appliance also maintains the mappings between subscriber IPv6 address and port, and NAT IPv4 address and port, for each large scale NAT64 session. These mappings are called large scale NAT64 mappings. From large scale NAT64 session entries and large scale NAT64 mapping entries, the NetScaler appliance recognizes a response packet (received from the Internet) as belonging to a particular NAT64 session.

When the appliance receives an IPv4 response packet belonging to a particular NAT64 session, it uses the information stored in the NAT64 session to translate the IPv4 packet into an IPv6 packet, and then sends the IPv6 response packet to the subscriber.

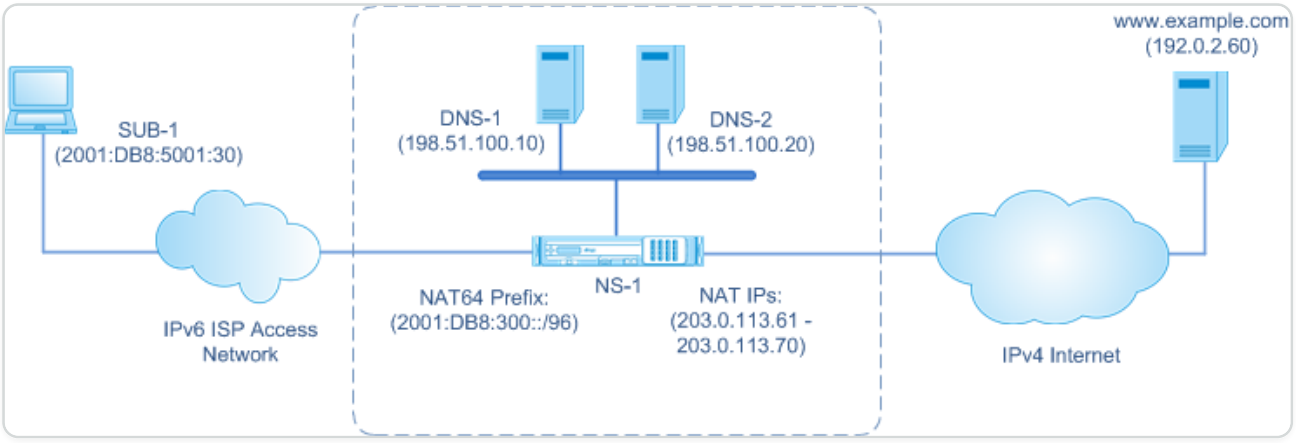
Example: Traffic Flow of NAT64 and DNS64 Deployment

Consider an example of a large scale NAT64 and DNS64 deployment consisting of NetScaler appliance NS-1 and two local DNS servers, DNS-1 and DNS-2, in an ISP's core network, and IPv6 subscriber SUB-1. SUB-1 is connected to NS-1 through the ISP's IPv6 access network. NS-1 includes large scale NAT64 and DNS64 configurations for enabling the communication between IPv6 subscriber SUB-1 and IPv4 hosts (internal and external).

Large scale NAT64 configuration includes a NAT64 prefix (2001:DB8:300::/96) and NAT IPv4 pool for translation of IPv6 requests to IPv4 requests and IPv4 responses to IPv6 responses.

DNS64 configuration includes a DNS load balancing virtual server LBVS-DNS64-1 (2001:DB8:9999::99) and a DNS64 prefix (2001:DB8:300::/96). LBVS-DNS64-1 represents local DNS server DNS-1 and DNS-2 to ISP's subscribers. The DNS64 prefix, which has the same value as the NAT64 prefix, is used for synthesizing DNS AAAA records from DNS A records received from DNS servers DNS-1 and DNS-2. NS-1 responds with a synthesized AAAA record to SUB-1 for a DNS request to resolve an IPv4 host.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



DNS64 Traffic Flow

Traffic flows between IPv6 subscriber SUB-1 and site `www.example.com`, which resides on an IPv4-only web server on the Internet, as follows:

1. IPv6 subscriber SUB-1 sends a DNS AAAA request for `www.example.com` to its designated DNS server (2001:DB8:9999::99).
2. DNS load balancing virtual server LBVS-DNS64-1 (2001:DB8:9999::99) on NetScaler appliance NS1 receives the AAAA request. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
3. DNS-1 returns an empty record or an error message, because there is no AAAA record available for `www.example.com`.
4. Because the DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of `www.example.com`.
5. DNS-1 responds with the A record of 192.0.2.60 for `www.example.com`.
6. DNS64 module on NS1 synthesizes an AAAA record for `www.example.com` by concatenating the DNS64 Prefix (2001:DB8:300::/96) associated with LBVS-DNS64-1, and IPv4 address (192.0.2.60) for `www.example.com` = 2001:DB8:300::192.0.2.60
7. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

NAT64 Traffic Flow

1. IPv6 subscriber SUB-1 sends a request to 2001:DB8:5001:30 `www.example.com`. The IPv6 packet has:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Source IP address = 2001:DB8:5001:30
- Source port = 2552
- Destination IP address = 2001:DB8:300::192.0.2.60
- Destination port = 80

2. IPv6 subscriber SUB-1 sends a request to 2001:DB8:5001:30 `www.example.com`. The IPv6 packet has:
   - Source IP address = 2001:DB8:5001:30
   - Source port = 2552
   - Destination IP address = 2001:DB8:300::192.0.2.60
   - Destination port = 80
3. When NS-1 receives the IPv6 packet, the large scale NAT64 module creates a translated IPv4 request packet with:
   - Source IP address = One of the IPv4 addresses available in the configured NAT pool (203.0.113.61)
   - Source port = One of ports available with the allocated NAT IPv4 address (3002)
   - Destination IP address = IPv4 address extracted from the IPv6 request's destination address by stripping the NAT64 prefix (2001:DB8:300::/96) from the IPv6 address (192.0.2.60)
   - Destination port = IPv6 request's destination port (80)
4. The large scale NAT64 module also creates mapping and session entries for this large scale NAT64 flow. The session and mapping entries include the following information:
   - Source IP address of the IPv6 packet = 2001:DB8:5001:30
   - Source port of the IPv6 packet = 2552
   - NAT IP address = 203.0.113.61
   - NAT port = 3002
   - NS-1 sends the resulting IPv4 packet to its destination on the Internet.
5. Upon receiving the request packet, the server for `www.example.com` processes the packet and sends a response packet to NS-1. The IPv4 response packet has:
   - Source IP address = 192.0.2.60

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Source port = 80
- Destination IP address = 203.0.113.61
- Destination port = 3002

6. Upon receiving the IPv4 response packet, NS-1 examines the large scale NAT64 mapping and session entries and finds that the IPv4 response packet belongs to a large scale NAT64 session. The large scale NAT64 module creates a translated IPv6 response packet:
   - Source IP address = 2001:DB8:300::192.0.2.60
   - Source port = 80
   - Destination IP address = 2001:DB8:5001:30
   - Destination port = 2552
7. NS-1 sends the translated IPv6 response to client SUB-1.

Large Scale NAT64 features Supported on NetScaler appliances

Large scale NAT64 on a NetScaler appliance supports the standard LSN feature set. For more information on these LSN features, see LSN Architecture.

Following are some of the large scale NAT64 features supported on NetScaler appliances:

- ALGs. Support of application Layer Gateway (ALG) for SIP, RTSP, FTP, ICMP, and TFTP protocols.
- Deterministic/Fixed NAT. Support for pre-allocation of blocks of ports to subscribers to minimize logging.
- Mapping. Support of Endpoint-independent mapping (EIM), Address-dependent mapping (ADM), and Address-Port dependent mapping (APDM).
- Filtering. Support of Endpoint-Independent Filtering (EIF), Address-Dependent Filtering (ADF), and Address-Port-Dependent Filtering (APDF).
- Quotas. Configurable limits on number of ports, sessions per subscriber, and sessions per LSN group.
- Static Mapping. Support for manually defining a large scale NAT64 mapping.
- Hairpin Flow. Support for communication between subscribers or internal hosts using NAT IP addresses.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- 464XLAT connections. Support for communication between IPv4-only applications on IPv6 subscriber hosts and IPv4 hosts on the Internet through IPv6 network.
- Variable length NAT64 and DNS64 prefixes. The NetScaler appliance supports defining NAT64 and DNS64 prefixes of lengths of 32, 40, 48, 56, 64, and 96.
- Multiple NAT64 and DNS64 prefix. The NetScaler appliance supports multiple NAT64 and DNS64 prefixes.
- LSN Clients. Support for specifying or identifying subscribers for large scale NAT64 by using IPv6 prefixes and extended ACL6 rules.
- Logging. Support for logging NAT64 sessions for law enforcement. In addition, the following are also supported for logging.
    - **Reliable SYSLOG**. Support for sending SYSLOG messages over TCP to external log servers for a more reliable transport mechanism.
    - **Load balancing of log servers**. Support for load balancing of external log servers for preventing storage of redundant log messages.
    - **Minimal Logging**. Deterministic LSN configurations or Dynamic LSN configurations with port block significantly reduce the large scale NAT64 log volume.
    - **Logging MSISDN information**. Support for including subscribers' MSISDN information in large scale NAT64 logs to identify and track subscriber activity over the Internet.

Points to Consider for Configuring Large Scale NAT64

Before you start configuring large scale NAT64 and DNS64, consider these points:

1. Make sure you understand the different components of large scale NAT64, described in RFCs.
2. The NetScaler appliance supports only the following ALGs for large Scale NAT64:
    - FTP
    - TFTP
    - ICMP
    - SIP
    - RTSP
3. In a high availability setup of two NetScaler appliances, large NAT64 session synchronization (connection mirroring) is not supported.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring DNS64

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

- Add DNS services. DNS services are logical representations of DNS servers for which the NetScaler appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see Load Balancing.
- Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy. A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude-rule and mapped-rule settings.
- Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it. The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see Load Balancing.

NOTE

The command line interface has separate commands for these two tasks, but the GUI combines them in a single dialog box.

- Enable caching of DNS records. Enable the global parameter for the NetScaler appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see Enabling Caching of DNS Records.

To create a service of type DNS by using the command line interface

At the command prompt, type:

```
add service <name> <IP> <serviceType> <port> …
```

To create a DNS64 action by using the command line interface

At the command prompt, type:

```
add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule
<expression>] [-excludeRule <expression>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create a DNS64 policy by using the command line interface

At the command prompt, type:

```
add dns policy64 <name> -rule <expression> -action <string>
```

To create a DNS load balancing virtual server by using the command line interface

At the command prompt, type:

```
add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED)
[-bypassAAAA ( YES | NO)] …
```

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the command line interface

At the command prompt, type:

```
bind lb vserver <name> <serviceName> ...

bind lb vserver <name> -policyName <string> -priority
<positive_integer> ...
```

Sample configuration:

```
add service SVC-DNS-1 203.0.113.50 DNS 53

Done

add service SVC-DNS-2 203.0.113.60 DNS 53

Done

add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96

Done

add dns Policy64 DNS64-Policy-1 -rule
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"CLIENT.IPv6.SRC.IN_SUBNET(2001:DB8:5001::/64)" -action DNS64-Action-1

Done

add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED

Done

bind lb vserver LBVS-DNS64-1 SVC-DNS-1

Done

bind lb vserver LBVS-DNS64-1 SVC-DNS-2

Done

bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2

Done
```

Configuring Large Scaler NAT64

A large scale NAT64 configuration on a NetScaler appliance uses the LSN commands sets. In a large scale NAT64 configuration, the LSN client entity specifies the IPv6 address or IPv6 network address, or ACL6 rules, for identifying IPv6 subscribers. A NAT64 configuration also includes an IPv6 profile, which specifies a NAT64 prefix.

Configuring NAT64 on a NetScaler appliance consists of the following tasks:

- Set the global LSN parameters. Global parameters include the amount of NetScaler memory reserved for the LSN feature and synchronization of LSN sessions in a high availability setup.
- Create an LSN client entity for identifying traffic from IPv6 subscribers. The LSN client entity refers to a set of IPv6 subscribers. The client entity includes IPv6 addresses or IPv6 network prefixes, or ACL6 rules, for identifying the traffic from these subscribers. An LSN client can be bound to only one LSN group. The command line interface has two commands for creating an LSN client entity and binding a subscriber to the LSN client entity. The GUI combines these two operations on a single screen.
- Create an LSN pool and bind NAT IP addresses to it. An LSN pool defines a pool of NAT IP addresses to be used by the NetScaler appliance to perform large scale NAT64. The command line interface has two commands for creating an LSN pool and binding NAT IP addresses to the LSN pool. The GUI combines these two operations on a single screen.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create an LSN IP6 profile. An LSN IP6 profile defines the NAT64 prefix for a large scale NAT64 configuration.
- (Optional) Create an LSN Transport Profile for a specified protocol. An LSN transport profile defines various timeouts and limits, such as maximum large scale NAT64 sessions and maximum ports usage that a subscriber can have for a given protocol. You bind an LSN transport profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. A profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN transport profile with default settings for TCP, UDP, and ICMP protocols is bound to an LSN group during its creation. This profile is called the default transport profile. An LSN transport profile that you bind to an LSN group overrides the default LSN transport profile for that protocol.
- (Optional) Create an LSN Application Profile for a specified protocol and bind a set of destination ports to it. An LSN application profile defines the LSN mapping and LSN filtering controls of a group for a given protocol and for a set of destination ports. For a set of destination ports, you bind an LSN profile for each protocol (TCP, UDP, and ICMP) to an LSN group. A profile can be bound to multiple LSN groups. An LSN application profile bound to an LSN group applies to all subscribers of an LSN client bound to the same group. By default, one LSN application profile with default settings for TCP, UDP, and ICMP protocols for all destination ports is bound to an LSN group during its creation. This profile is called a default application profile. When you bind an LSN application profile, with a specified set of destination ports, to an LSN group, the bound profile overrides the default LSN application profile for that protocol at that set of destination ports. The command line interface has two commands for creating an LSN application profile and binding a set of destination ports to the LSN application profile. The GUI combines these two operations on a single screen.
- Create an LSN Group and bind LSN pools, LSN IPv6 profile, (optional) LSN transport profiles, and (optional) LSN application profiles to the LSN group. An LSN group is an entity consisting of an LSN client, an LSN IPv6 profile, LSN pool(s), LSN transport profile(s), and LSN application profiles(s). A group is assigned parameters, such as port block size and logging of LSN sessions. The parameter settings apply to all the subscribers of an LSN client bound to the LSN group. Only one LSN IPv6 profile can be bound to an LSN group, and an LSN IPv6 profile bound to an LSN group cannot be bound to other LSN groups. Only LSN Pools and LSN groups with the same NAT type settings can be bound together. Multiples LSN pools can be bound to an LSN group. Only one LSN client entity can be bound to an LSN group, and an LSN client entity bound to an LSN group cannot be bound to other LSN groups. The command line interface has two commands for creating an LSN group and binding LSN pools, LSN transport profiles, and LSN application profiles to the LSN group. The GUI combines these two operations in a single screen.

Configuration Using the Command Line

You can create different configurations using the command line interface. Follow the steps given below.

To create an LSN client by using the command line interface

At the command prompt, type:

```
add lsn client <clientname

show lsn client
```

To bind an IPv6 network or an ACL6 rule to an LSN client by using the command line interface

At the command prompt, type:

```
bind lsn client <clientname> (-network6 <ipv6_addr|*>| -acl6name <string>)

show lsn client
```

To create an LAN pool by using the command line interface

At the command prompt, type:

```
add lsn pool <poolname>

show lsn pool <poolname>
```

To bind NAT IP addresses to an LSN pool by using the command line interface

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn pool <poolname> <lsnip>

show lsn pool
```

NOTE

For removing NAT IP (LSN IP addresses) addresses from an LSN pool, use the unbind lsn pool command.

To configure an LSN IPv6 profile by using the command line interface

At the command prompt, type:

```
add lsn ip6profile <name> –type NAT64 -natprefix <ipv6_addr|*>

show lsn ip6profile
```

To create an LSN transport profile by using the command line interface

At the command prompt, type:

```
add lsn transportprofile <transportprofilename> <transportprotocol> [-
sessiontimeout <secs>] [-finrsttimeout <secs>] [-portquota
<positive_integer>] [-sessionquota <positive_integer>] [-
portpreserveparity ( ENABLED | DISABLED )] [-portpreserverange (ENABLED |
DISABLED )] [-syncheck ( ENABLED | DISABLED )]

show lsn transportprofile
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create an LSN application profile by using the command line interface

At the command prompt, type:

```
add lsn appsprofile <appsprofilename> <transportprotocol> [-ippooling
(PAIRED | RANDOM )] [-mapping <mapping>] [-filtering <filtering>][-
tcpproxy ( ENABLED | DISABLED )]

show lsn appsprofile
```

To bind an application protocol port range to an LSN application profile by using the command line interface

At the command prompt, type:

```
bind lsn appsprofile <appsprofilename> <lsnport>

show lsn appsprofile
```

To create an LSN group by using the command line interface

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-nattype ( DYNAMIC |
DETERMINISTIC )] [-portblocksize <positive_integer>] [-logging(ENABLED |
DISABLED )] [-sessionLogging ( ENABLED | DISABLED )][-sessionSync
( ENABLED | DISABLED )] [-snmptraplimit<positive_integer>] [-ftp ( ENABLED
| DISABLED )] [-sipalg ( ENABLED | DISABLED )] [-rtspalg ( ENABLED |
DISABLED )] [-ip6profile <string>]

show lsn group
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind LSN protocol profiles and LSN pools to an LSN group by using the command line interface

At the command prompt, type:

```
bind lsn group <groupname> (-poolname <string> | -transportprofilename
<string> | -httphdrlogprofilename <string> | -appsprofilename <string> |
-sipalgprofilename <string> | rtspalgprofilename <string>)

show lsn group
```

Sample Large Scale NAT64 Configurations

Here are some sample configurations of large scale NAT64:

Simple large scale NAT64 configuration with default settings:

```
add lsn client LSN-NAT64-CLIENT-1

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

add lsn pool LSN-NAT64-POOL-1

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
```

Simple large scale NAT64 configuration with an extended ACL6 rule for identifying subscribers:

```
add ns acl6 LSN-NAT64-ACL-2 ALLOW –srcIPv6 = 2001:DB8:5002::20 -
2001:DB8:5002::200

apply acl6s

add lsn client LSN-NAT64-CLIENT-2

bind lsn client LSN-NAT64-CLIENT-2 –acl6name LSN-NAT64-ACL-2

add lsn pool LSN-NAT64-POOL-2

bind lsn pool LSN-NAT64-POOL-2 203.0.113.5-203.0.113.10

add lsn ip6profile LSN-NAT64-PROFILE-2 -type NAT64 -natprefix
2001:DB8:302::/96

add lsn group LSN-NAT64-GROUP-2 -clientname LSN-NAT64-CLIENT-2 -ip6profile
LSN-NAT64-PROFILE-2
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group LSN-NAT64-GROUP-2 -poolname LSN-NAT64-POOL-2
```

Large scale NAT64 configuration with deterministic NAT resource allocation:

```
add lsn client LSN-NAT64-CLIENT-7

bind lsn client LSN-NAT64-CLIENT-7 -network6 2001:DB8:1002::7/128

add lsn pool LSN-NAT64-POOL-7 -nattype DETERMINISTIC

bind lsn pool LSN-NAT64-POOL-7 203.0.113.24-203.0.113.27

add lsn ip6profile LSN-NAT64-PROFILE-7 -type NAT64 -natprefix
2001:DB8:307::/96

add lsn group LSN-NAT64-GROUP-7 -clientname LSN-NAT64-CLIENT-7 -ip6profile
LSN-NAT64-PROFILE-7 -nattype DETERMINISTIC -portblocksize 256

bind lsn group LSN-NAT64-GROUP-7 -poolname LSN-POOL-7
```

Configuring Application Layer Gateways for Large Scale NAT64

For some Application layer protocols, the IP addresses and protocol port numbers are also communicated in the packet payload. Application Layer Gateway for a protocol parses the packet's

© 1997–2026 Citrix Systems, Inc. All rights reserved.

payload and does necessary changes to ensure that the protocol continues to work over large scale NAT64.

The NetScaler appliance supports ALG for the following protocols for large scale NAT64:

- FTP
- ICMP
- TFTP
- SIP
- RTSP

Application Layer Gateway for FTP, ICMP, and TFTP Protocols

You can enable or disable ALG for the FTP protocol for an large scale NAT64 configuration by enabling or disabling the FTP ALG option of the LSN group of the configuration.

ALG for the ICMP protocol is enabled by default, and there is no provision to disable it.

ALG for the TFTP protocol is disabled by default. TFTP ALG is enabled automatically for an large scale NAT64 configuration when you bind a UDP LSN application profile, with endpoint-independent-mapping, endpoint-independent filtering, and destination port as 69 (well-known port for TFTP), to the LSN group.

Application Layer Gateway for SIP Protocol

Using Large Scale NAT64 with Session Initiation Protocol (SIP) is complicated, because SIP messages contain IP addresses in the SIP headers as well as in the SIP body. When LSN is used with SIP, the SIP headers contain information about the caller and the receiver, and the device translates this information to hide it from the outside network. The SIP body contains the Session Description Protocol (SDP) information, which includes IP addresses and port numbers for transmission of the media. SIP ALG for large scale NAT64 is compliant with RFC 3261, RFC 3581, RFC 4566, and RFC 4475.

NOTE

SIP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

Limitations of SIP ALG

SIP ALG for large scale NAT64 has the following limitations:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Only SDP payload is supported.
- The following are not supported:
  - Multicast IP addresses
  - Encrypted SDP
  - SIP TLS
  - FQDN translation
  - SIP layer authentication
  - Traffic Domains
  - Admin partitions
  - Multipart body
  - Line folding

Configuring SIP ALG

You need to configure the SIP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuration Large Scale NAT64. While configuring LSN, make sure that you:

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Create a SIP ALG profile and make sure that you define either the source port range or destination port range. Bind the SIP ALG profile to the LSN group.
- Enable SIP ALG in the LSN group.

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-sipalg ( ENABLED |
DISABLED )]

show lsn group <groupname>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable SIP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn sipalgprofile <sipalgprofilename>[-dataSessionIdleTimeout
<positive_integer>][-sipSessionTimeout <positive_integer>] [-
registrationTimeout <positive_integer>] [-sipsrcportrange <port[-port]>]
[-sipdstportrange <port[-port]>] [-openRegisterPinhole ( ENABLED |
DISABLED )] [-openContactPinhole ( ENABLED | DISABLED )] [-openViaPinhole
( ENABLED | DISABLED )] [-openRecordRoutePinhole ( ENABLED | DISABLED )]-
sipTransportProtocol ( TCP | UDP ) [-openRoutePinhole ( ENABLED |
DISABLED )] [-rport ( ENABLED | DISABLED )]

show lsn sipalgprofile <sipalgprofilename
```

Sample Configuration

The following sample large scale NAT64 configuration, SIP ALG is enabled for TCP traffic from subscriber devices in the network 2001:DB8:1003::/96.

```
add lsn client LSN-NAT64-CLIENT-9

Done

bind lsn client LSN-NAT64-CLIENT-9 -network6 2001:DB8:1002::/96

Done

add lsn pool LSN-NAT64-POOL-9

Done

bind lsn pool LSN-NAT64-POOL-9 203.0.113.90
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add lsn ip6profile LSN-NAT64-PROFILE-9 -type NAT64 -natprefix
2001:DB8:309::/96

Done

add lsn appsprofile LSN-NAT64-APPS-PROFILE-9 TCP -ippooling PAIRED –
mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn sipalgprofile SIPALGPROFILE-9  -sipdstportrange 5060  -
sipTransportProtocol TCP

Done

add lsn group LSN-NAT64-GROUP-9 -clientnameLSN-NAT64-CLIENT-9 -ip6profile
LSN-NAT64-PROFILE-7 -sipalg ENABLED

Done

bind lsn group LSN-NAT64-GROUP-9 -poolnameLSN-NAT64-POOL-9

Done

bind lsn group LSN-NAT64-GROUP-9 -appsprofilename LSN-NAT64-APPS-PROFILE-9

Done

bind lsn group LSN-NAT64-GROUP-9 -sipalgprofilename SIPALGPROFILE-9

Done
```

Application Layer Gateway for RTSP Protocol

Real Time Streaming Protocol (RTSP) is an application-level protocol for the transfer of real-time media data. Used for establishing and controlling media sessions between end points, RTSP is a control channel protocol between the media client and the media server. The typical communication is between a client and a streaming media server.

Streaming media from a private network to a public network requires translating IP addresses and port numbers over the network. NetScaler functionality includes an Application Layer Gateway (ALG) for RTSP, which can be used with Large Scale NAT (LSN) to parse the media stream and make any necessary changes to ensure that the protocol continues to work over the network.

How IP address translation is performed depends on the type and direction of the message, and the type of media supported by the client-server deployment. Messages are translated as follows:

- Outbound request—Private IP address to NetScaler owned public IP address called LSN IP address.
- Inbound response—LSN IP address to private IP address.
- Inbound request—No translation.
- Outbound response—Private IP address to LSN pool IP address.

NOTE

RTSP ALG is supported in a NetScaler standalone appliance, in a NetScaler high availability setup, as well as in a NetScaler cluster setup.

Limitations of RTSP ALG

The RTSP ALG does not support the following:

- Multicast RTSP sessions
- RTSP session over UDP
- Admin partitions
- RTSP Authentication
- HTTP tunneling

Configuring RTSP ALG

Configure RTSP ALG as part of the LSN configuration. For instructions on configuring LSN, see Configuring Large Scale NAT64. While configuring, make sure that you:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Set the following parameters while adding an LSN application profile:
  - IP Pooling = PAIRED
  - Address and Port Mapping = ENDPOINT-INDEPENDENT
  - Filtering = ENDPOINT-INDEPENDENT
- Enable RTSP ALG in the LSN group
- Create a RTSP ALG profile and bind the RTSP ALG profile to the LSN group

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-rtspalg ( ENABLED |
DISABLED )]

show lsn group <groupname>
```

To enable RTSP ALG for an LSN configuration by using the CLI

At the command prompt, type:

```
add lsn rtspalgprofile <rtspalgprofilename> [-rtspIdleTimeout
<positive_integer>] -rtspportrange <port[-port]> [-rtspTransportProtocol
(TCP|UDP)]

show lsn rtspalgprofile <rtspalgprofilename>
```

Sample RTSP ALG Configuration

The following sample large scale NAT64 configuration, RTSP ALG is enabled for TCP traffic from subscriber devices in the network 2001:DB8:1002::/96.

```
add lsn client LSN-NAT64-CLIENT-9

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn client LSN-NAT64-CLIENT-9 -network6 2001:DB8:1002::/96

Done

add lsn pool LSN-NAT64-POOL-9

Done

bind lsn pool LSN-NAT64-POOL-9 203.0.113.90

Done

add lsn ip6profile LSN-NAT64-PROFILE-9 -type NAT64 -natprefix
2001:DB8:309::/96

Done

add lsn appsprofile LSN-NAT64-APPS-PROFILE-9 TCP -ippooling PAIRED –
mapping ENDPOINT-INDEPENDENT -filtering ENDPOINT-INDEPENDENT

Done

add lsn rtspalgprofile RTSPALGPROFILE-9 -rtspIdleTimeout 1000
-rtspportrange 554

Done

add lsn group LSN-NAT64-GROUP-9 -clientname LSN-NAT64-CLIENT-9 -ip6profile
LSN-NAT64-PROFILE-7 -rtspalg ENABLED

Done

bind lsn group LSN-NAT64-GROUP-9 -poolname LSN-NAT64-POOL-9

Done

bind lsn group LSN-NAT64-GROUP-9 -appsprofilename LSN-NAT64-APPS-PROFILE-9

Done

bind lsn group LSN-NAT64-GROUP-9  -rtspalgprofilename RTSPALGPROFILE-9
```

```
Done
```

Configuring Static Large Scale NAT64 Maps

The NetScaler appliance supports manual creation of NAT64 mappings, which contain the mapping between the following information:

- Subscriber's IP address and port
- NAT IP address and port

Static Large Scale NAT64 mappings are useful in cases where you want to ensure that the IPv4 connections initiated to a NAT IP address:port are IPv6 translated and mapped to the subscriber IP address:port (for example, web servers located in the internal network).

To create a Large Scale NAT64 mapping by using the command line

At the command prompt, type:

```
add lsn static <name> <transportprotocol> <subscrIP> <subscrPort>
 [<natIP> [<natPort>]] [-destIP <ip_addr> [-dsttd <positive_integer>]]

show lsn static
```

Wildcard Port Static Large Scale NAT64 Maps

A static large scale NAT64 mapping entry is usually a one-to-one mapping between a subscriber IPv6 address:port and a NAT IPv4 address:port. A one-to-one static large scale NAT64 mapping entry exposes only one port of the subscriber IP address to the Internet.

Some situations might require exposing all ports (64K - limited to the maximum number of ports of a NAT IPv4 address) of a subscriber IP address to the Internet (for example, a server hosted on an internal network and running a different service on each port). To make these internal services accessible through the Internet, you have to expose all the ports of the server to the Internet.

One way to meet this requirement is to add 64 thousand one-to-one static mapping entries, one mapping entry for each port. Creating those entries is very cumbersome and a big task. Also, this large number of configuration entries might lead to performance issues in the NetScaler appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

A simpler method is to use wildcard ports in a static mapping entry. You just need to create one static mapping entry with NAT-port and subscriber-port parameters set to the wildcard character (*), and the protocol parameter set to ALL, to expose all the ports of a subscriber IP address for all protocols to the Internet.

For a subscriber's inbound or outbound connections matching a wildcard static mapping entry, the subscriber's port does not change after the NAT operation. When a subscriber-initiated connection to the Internet matches a wildcard static mapping entry, the NetScaler appliance assigns a NAT port that has the same number as the subscriber port from which the connection is initiated. Similarly, an Internet host gets connected to a subscriber's port by connecting to the NAT port that has the same number as the subscriber's port.

To configure the NetScaler appliance to provide access to all ports of a subscriber IPv6 address, create a wildcard static map with the following mandatory parameter settings:

- Protocol=ALL
- Subscriber port = *
- NAT port = *

In a wildcard static map, unlike in a one-to-one static map, setting the NAT IP parameter is mandatory. Also, the NAT IP address assigned to a wildcard static map cannot be used for any other subscribers.

To create a wildcard static map by using the command line interface

At the command prompt, type:

```
add lsn static <name> ALL <subscrIP> *  <natIP> * [-td <positive_integer>]
[-destIP <ip_addr>

show lsn static
```

In the following sample configuration of a wildcard static map, all ports of a subscriber whose IP address is 2001:DB8:5001::3 are made accessible through NAT IP 203.0.11.33.

```
add lsn static NAT64-WILDCARD-STATIC-1 ALL 2001:DB8:5001::3 * 203.0.113.33
*
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Logging and Monitoring Large Scale NAT64

You can log large scale NAT64 information to diagnose and troubleshoot problems, and to meet legal requirements. You can monitor the performance of the large scale NAT64 deployment by using statistical counters and displaying the related current sessions.

Logging Large Scale NAT64

Logging large scale NAT64 information is required for ISPs to meet legal requirements and identify the source of traffic at any given time.

A log message for a large scale NAT64 mapping entry consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced.
- Time stamp.
- Entry type (MAPPING).
- Whether the mapping entry was created or deleted.
- Subscriber's IP address, port, and traffic domain ID.
- NAT IP address and port.
- Protocol name.
- Destination IP address, port, and traffic domain ID might be present, depending on the following conditions:
  - Destination IP address and port are not logged for endpoint-independent mapping.
  - Only the destination IP address is logged for address-dependent mapping. The port is not logged.
  - Destination IP address and port are logged for address-port-dependent mapping.

A log message for a large scale NAT64 session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp
- Entry type (SESSION)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Whether the session is created or removed
- Subscriber's IP address, port, and traffic domain ID
- NAT IP address and port
- Protocol name
- Destination IP address, port, and traffic domain ID

The following table displays sample large scale NAT64 log entries of each type stored on the configured log servers. The log entries show that a subscriber whose IPv6 address is 2001:db8:5001::9 was connected to destination IP:port 23.0.0.1:80 through NAT IP:port 203.0.113.63:45195 on April 7, 2016, from 14:07:57 GMT to 14:10:59 GMT.

LOG ENTRY TYPE	SAMPLE LOG ENTRY
Session Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_SESSION 5532 0 : SESSION CREATED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP
Mapping Creation	04/07/2016:14:07:57 GMT Informational 0-PPE-10 : default LSN LSN_ADDR_MAPPING 5533 0 : ADM CREATED Client IP-Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:TD 23.0.0.1:80, Protocol: TCP

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuration Steps

You can configure logging of large scale NAT64 information for a large scale NAT64 configuration by setting the LSN groups's logging and session logging parameters. These are group level parameters and are disabled by default. The NetScaler appliance logs large scale NAT64 sessions for an LSN group only when both logging and session logging parameters are enabled.

The following table displays the logging behavior for an LSN group for various settings of logging and session logging parameters.

LOGGING	SESSION LOGGING	LOGGING BEHAVIOR
Enabled	Enabled	Logs LSN mapping entries as well as LSN sessions
Enabled	Disabled	Logs LSN mapping entries but not LSN sessions
Disabled	Enabled	Logs neither mapping entries nor LSN sessions

To log large scale NAT64 information by using the CLI

To set the logging and session logging parameters while adding an LSN group, at the command prompt, type:

```
add lsn group <groupname> -clientname <string> [-logging (ENABLED|
DISABLED)] [-sessionLogging (ENABLED|DISABLED)]

show lsn group
```

To set the logging and session logging parameters for an existing LSN group, at the command prompt, type:

```
set lsn group <groupname> [-logging (ENABLED|DISABLED)] [-sessionLogging
(ENABLED|DISABLED)]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lsn group
```

Sample Configuration

In this example of large scale NAT64 configuration, logging and session logging paramters are enabled for LSN group LSN-NAT64-GROUP-1.

The NetScaler appliance logs large scale NAT64 session and mapping information for connections from subscribers (in the network 2001:DB8:5001::/96).

Sample configuration:

```
add lsn client LSN-NAT64-CLIENT-1 Done

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1  -logging ENABLED -sessionLogging ENABLED

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Logging MSISDN Information for Large Scale NAT64

A Mobile Station Integrated Subscriber Directory Number (MSISDN) is a telephone number uniquely identifying a subscriber across multiple mobile networks. The MSISDN is associated with a country code and a national destination code identifying the subscriber's operator.

You can configure a NetScaler appliance to include MSISDNs in large scale NAT64 LSN log entries for subscribers in mobile networks. The presence of MSISDNs in the LSN logs facilitates faster and accurate back tracing of a mobile subscriber who has violated a policy or law, or whose information is required by lawful interception agencies.

The following sample LSN log entries include MSISDN information for a connection from a mobile subscriber in an LSN configuration. The log entries show that a mobile subscriber whose MSISDN is E164:5556543210 and IPv6 address is 2001:db8:5001::9 was connected to destination IP:port 23.0.0.1:80 through the NAT IP:port 203.0.113.63:45195 on April 7, 2016, from 14:07:57 GMT to 14:10:59 GMT.

LOG ENTRY TYPE	SAMPLE LOG ENTRY

	Port:TD **2001:db8:5001::9-34937:0**, NatIP:NatPort 203.0.113.63:45195, Destination IP:Port:TD 23.0.0.1:0:80, Protocol: TCP

Configuration Steps

Perform the following tasks for including MSISDN information in LSN logs:

- **Create an LSN log profile**. An LSN log profile includes the log subscriber ID parameter, which specifies whether to or not to include the MSISDN information in the LSN logs of an LSN configuration.
- Bind the LSN log profile to an LSN group of an LSN configuration.Bind the created LSN log profile to an LSN group of an LSN configuration by setting the log profile name parameter to the created LSN log profile name. MSISDN information is included in all LSN logs related to mobile subscribers of this LSN group.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logSubscriberID ( ENABLED |
DISABLED )

show lsn logprofile
```

To bind an LSN log profile to an LSN group of an NAT64 LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Sample Configuration

In this example of NAT64 LSN configuration, the LSN log profile LOG-PROFILE-MSISDN-1 has the log subscriber ID parameter enabled. LOG-PROFILE-MSISDN-1 is bound to LSN group LSN-NAT64-GROUP-1. MSISDN information is included in the LSN session and LSN mapping logs for connections from mobile subscribers (in network 2001:DB8:5001::/96).

```
add lsn logprofile  LOG-PROFILE-MSISDN-1  -logSubscriberID ENABLED

Done

add lsn client LSN-NAT64-CLIENT-1

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1

Done

bind lsn group LSN-NAT64-GROUP-1 -logprofilename  LOG-PROFILE-MSISDN-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Compact Logging for Large Scale NAT

Logging LSN information is one of the important functions needed by ISPs to meet legal requirements and be able to identify the source of traffic at any given time. This eventually results in a huge volume of log data, requiring the ISPs to make large investments to maintain the logging infrastructure.

Compact logging is a technique for reducing the log size by using a notational change involving short codes for event and protocol names. For example, C for client, SC for session created, and T for TCP. Compact logging results in an average of 40 percent reduction in log size.

Configuration Steps

Perform the following tasks for logging LSN information in compact format:

1. Create an LSN log profile. An LSN log profile includes the Log Compact parameter, which specifies whether to or not to log information in compact format for an LSN configuration.
2. Bind the LSN log profile to an LSN group of an LSN configuration. Bind the created LSN log profile to an LSN group of an LSN configuration by setting the Log Profile Name parameter to the created LSN log profile name. All sessions and mappings for this LSN group are logged in compact format.

To create an LSN log profile by using the CLI

At the command prompt, type:

```
add lsn logprofile <logprofilename> -logCompact (ENABLED|DISABLED)

show lsn logprofile
```

To bind an LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group <groupname> -logProfileName <lsnlogprofilename>

show lsn group
```

Sample Configuration for NAT64:

```
add lsn logprofile  LOG-PROFILE-COMPACT-1 -logCompact ENABLED

Done

add lsn client LSN-NAT64-CLIENT-1

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lsn group LSN-NAT64-GROUP-1 –logProfileName LOG-PROFILE-COMPACT-1

Done
```

Logging HTTP Header Information

The NetScaler appliance can log request header information of an HTTP connection that is using the NetScaler large scale NAT64 functionality. The following header information of an HTTP request packet can be logged:

- URL that the HTTP request is destined to
- HTTP Method specified in the HTTP request
- HTTP version used in the HTTP request
- IPv6 address of the subscriber that sent the HTTP request

The HTTP header logs can be used by ISPs to see the trends related to the HTTP protocol among a set of subscribers. For example, an ISP can use this feature to find out the most popular website among a set of subscribers.

Configuration Steps

Perform the following tasks for configuring the NetScaler appliance to log HTTP header information:

- Create an HTTP header log profile. An HTTP header log profile is a collection of HTTP header attributes (for example, URL and HTTP method) that can be enabled or disabled for logging.
- Bind the HTTP header to an LSN group of a large scale NAT64 configuration. Bind the HTTP header log profile to an LSN group of an LSN configuration by setting the HTTP header log profile name parameter to the name of the created HTTP header log profile. The NetScaler appliance then logs HTTP header information of any HTTP requests related to the LSN group. An HTTP header log profile can be bound to multiple LSN groups, but an LSN group can have only one HTTP header log profile.

To create an HTTP header log profile by using the the command line interface

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn httphdrlogprofile <httphdrlogprofilename> [-logURL ( ENABLED |
DISABLED )] [-logMethod ( ENABLED | DISABLED )] [-logVersion ( ENABLED |
DISABLED )] [-logHost ( ENABLED | DISABLED )]

show lsn httphdrlogprofile
```

To bind an HTTP header log profile to an LSN group by using the the command line interface

At the command prompt, type:

```
bind lsn group <groupname> -httphdrlogprofilename <string>

show lsn group <groupname>
```

Sample Configuration

```
add lsn httphdrlogprofile HTTP-HEADER-LOG-1

Done

add lsn client LSN-NAT64-CLIENT-1 Done

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1

Done

bind lsn group LSN-NAT64-GROUP-1 -httphdrlogprofilename HTTP-HEADER-LOG-1

Done
```

Displaying Current Large Scale NAT64 Sessions

You can display the current large scale NAT64 sessions in order to detect any unwanted or inefficient sessions on the NetScaler appliance. You can display all or some large scale NAT64 sessions on the basis of selection parameters.

NOTE

When more than a million large scale NAT64 sessions exist on the NetScaler appliance, Citrix recommends using the selection parameters to display selected large scale NAT64 sessions instead of displaying all of them.

To display all large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
show lsn session –nattype NAT64
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To display selective large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
show lsn session –nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname
<string>] [-natIP <ip_addr> [-natPort <port>]]
```

Displaying Large Scale NAT64 Statistics

You can display statistics related to large scale NAT64 module, and evaluate its performance or troubleshoot problems. You can display a summary of statistics of all large scale NAT64 configurations or of a particular large scale NAT64 configuration. The statistical counters reflect events since the NetScaler appliance was last restarted. All these counters are reset to 0 when the NetScaler appliance is restarted.

To display total statistics of large scale NAT64 by using the command line interface

At the command prompt, type:

```
stat lsn nat64
```

To display statistics for a specified large scale NAT64 configuration by using the command line interface

At the command prompt, type:

```
stat lsn group <groupname>
```

Clearing Large Scale NAT64 Sessions

You can remove any unwanted or inefficient large scale NAT64 sessions from the NetScaler appliance. The appliance immediately releases resources (such as NAT IP address, port, and memory) allocated for these sessions, making the resources available for new sessions. The appliance also drops all the subsequent packets related to these removed sessions. You can remove all or selected large scale NAT64 sessions from the NetScaler appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To clear all large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
flush lsn session –nattype NAT64

show lsn session –nattype NAT64
```

To clear selective large scale NAT64 sessions by using the command line interface

At the command prompt, type:

```
flush lsn session –nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname
<string>] [-natIP <ip_addr> [-natPort <port>]]

show lsn session –nattype NAT64 [-network6 <ipv6_addr|*>] [-clientname
<string>] [-natIP <ip_addr> [-natPort <port>]]
```

Sample configuration:

Clear all large scale NAT64 sessions existing on a NetScaler appliance

```
flush lsn session  –nattype NAT64

Done
```

Clear all large scale NAT64 sessions related to client entity LSN-NAT64-CLIENT-1

```
flush lsn session –nattype NAT64 -clientname LSN-NAT64-CLIENT-1

Done
```

Clear all large scale NAT64 sessions related to a subscriber network (2001:DB8:5001::/96) of LSN client entity LSN-NAT64-CLIENT-2

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
flush lsn session –nattype NAT64 –network6 2001:DB8:5001::/96 -clientname
LSN-NAT64-CLIENT-2

Done
```

IPFIX Logging

The NetScaler appliance supports sending information about LSN events in Internet Protocol Flow Information Export (IPFIX) format to the configured set of IPFIX collector(s). The appliance uses the existing AppFlow feature to send LSN events in IPFIX format to the IPFIX collectors.

IPFIX based logging is available for the following NAT64 related events:

- Creation or deletion of an LSN session.
- Creation or deletion of an LSN mapping entry.
- Allocation or de-allocation of port blocks in the context of deterministic NAT.
- Allocation or de-allocation of port blocks in the context of dynamic NAT.
- Whenever subscriber session quota is exceeded.

Points to Consider before you Configure IPFIX logging

Before you start configuring IPSec ALG, consider the following points:

- You must configure the AppFlow feature and IPFIX collector(s) on the NetScaler appliance. For instructions, see Configuring the AppFlow feature.

Configuration Steps

Perform the following tasks for logging LSN information in IPFIX format:

- **Enable LSN logging in the AppFlow® configuration**. Enable the LSN logging parameter as part of AppFlow configuration.
- **Create an LSN log profile**. An LSN log profile includes the IPFIX parameter that enables or disables the log information in IPFIX format.
- **Bind the LSN log profile to an LSN group of an LSN configuration**. Bind the LSN log profile to one or multiple LSN group(s). Events related to the bound LSN group will be logged in IPFIX format.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable LSN logging in the AppFlow configuration by using the CLI

At the command prompt, type:

```
set appflow param -lsnLogging ( ENABLED | DISABLED )

show appflow param
```

To create an LSN log profile by using the CLIAt the command prompt, type

At the command prompt, type:

```
set lsn logprofile <logProfileName>  -logipfix ( ENABLED | DISABLED )

show lsn logprofile
```

To bind the LSN log profile to an LSN group of an LSN configuration by using the CLI

At the command prompt, type:

```
bind lsn group <groupname>  -logProfileName <lsnlogprofilename>

show lsn group
```

To create an LSN log profile by using the GUI

Navigate to **System** > **Large Scale NAT** > **Profiles**, click **Log** tab, and then add a log profile.

To bind the LSN log profile to an LSN group of an LSN configuration by using the GUI

1. Navigate to **System** > **Large Scale NAT** > **LSN Group,** open the **LSN** group.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. In **Advanced Settings,** click **+ Log Profile** to bind the created Log profile to the LSN group.

Port Control Protocol for Large Scale NAT64

NetScaler appliances now support Port Control Protocol (PCP) for large scale NAT (LSN). Many of an ISP's subscriber applications must be accessible from Internet (for example, Internet of Things (IOT) devices, such as an IP camera that provides surveillance over the Internet). One way to meet this requirement is to create static large scale NAT (LSN) maps. But for a very large number of subscribers, creating static LSN NAT maps is not a feasible solution.

Port Control Protocol (PCP) enables a subscriber to request specific LSN NAT mappings for itself and/or for other 3rd party devices. The large scale NAT device creates an LSN map and sends it to the subscriber. The subscriber sends the remote devices on the Internet the NAT IP address:NAT port at which they can connect to the subscriber.

Applications usually send frequent keep-alive messages to the large scale NAT device so that their LSN mappings do not time out. PCP helps reduce the frequency of such keep-alive messages by enabling the applications to learn the timeout settings of the LSN mappings. This helps reduce bandwidth consumption on the ISP’s access network and battery consumption on mobile devices.

PCP is a client-server model and runs over the UDP transport protocol. A NetScaler appliance implements the PCP server component and is compliant with RFC 6887.

Configuration Steps

Perform the following tasks for configuring PCP:

- **(Optional) Create a PCP profile**. A PCP profile includes settings for PCP related parameters (for example, to listen for mapping and peer PCP requests). A PCP profile can be bound to a PCP server. A PCP profile bound to a PCP server applies all its settings to the PCP server. A PCP profile can be bound to multiple PCP servers. By default, one PCP profile with default parameters settings is bound to all PCP servers. A PCP profile that you bind to a PCP server overrides the default PCP profile settings for that server. A default PCP profile has the following parameter settings:
    - Mapping: Enabled
    - Peer: Enabled
    - Minimum map life: 120 seconds
    - Maximum max life: 86400 seconds
    - Announce count: 10

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Third Party: Disabled

- **Create a PCP server and bind a PCP profile to it**. Create a PCP server on the NetScaler appliance to listen for PCP related requests and messages from the subscribers. A Subnet IP (SNIP) or (SNIP6) address must be assigned to a PCP server to access it. By default, a PCP server listens on port 5351.
- **Bind the PCP server to an LSN group of an LSN configuration**. Bind the created PCP server to an LSN group of an LSN configuration by setting the PCP Server parameter to specify the created PCP server. The created PCP server can be accessed only by the subscribers of this LSN group.

NOTE

A PCP server for a large scale NAT configuration does not serve requests from subscribers that are identified from ACL rules.

To create a PCP profile by using the CLI

At the command prompt, type:

```
add pcp profile <name> [-mapping ( ENABLED | DISABLED )] [-peer ( ENABLED
| DISABLED )] [-minMapLife <secs>]  [-maxMapLife <secs>] [-
announceMultiCount <positive_integer>][-thirdParty ( ENABLED | DISABLED )]

show pcp profile <name>
```

To create a PCP server by using the CLI

At the command prompt, type:

```
add pcp server <name> <IPAddress> [-port <portNum|*>] [-pcpProfile
<string>]

show pcp server <name>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Sample Configuration for NAT64

In the following sample configuration, PCP server PCP-SERVER-1, with PCP settings from PCP-PROFILE-1,is bound to LSN group LSN-NAT64-GROUP-1. PCP-SERVER-1 serves PCP requests from IPv6 subscribers in network 2001:DB8:5001::/96.

Sample configuration:

```
add pcp profile PCP-PROFILE-1 -minMapLife 400

Done

add pcp server PCP-SERVER-1 2001:DB8:6001::90  -pcpProfile PCP-PROFILE-1

Done

add lsn client LSN-NAT64-CLIENT-1

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1

Done

bind lsn pool LSN-NAT64-POOL-1 203.0.113.61 - 203.0.113.70

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-PROFILE-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn group LSN-NAT64-GROUP-1 –pcpServer PCP-NAT64-SERVER-1

Done
```

LSN64 in a cluster setup

Large scale NAT64 configurations are supported on a NetScaler cluster setup.

A NetScaler cluster is a group of NetScaler appliances that are configured and managed as a single system. A NetScaler cluster provides scalability and availability. Each NetScaler appliance in a cluster setup acts as an independent LSN entity and is managed as a single system.

The LSN configuration in a cluster setup is same as in a standalone appliance except for a specific pool of LSN IP addresses are owned by only one node at a time. In other words, an LSN IP pool entity is configured as a spotted entity in a particular node. All the nodes of a cluster setup can have a specific LSN IP pool entity. To make sure that the packets related to an LSN session are received on the same cluster node that performed the NAT operation, policy based backplane (PBS) steering is configured. PBS steers the received related packets of an LSN session to the same cluster node.

Sample configuration:

```
add lsn client LSN-NAT64-CLIENT-1

Done

bind lsn client LSN-NAT64-CLIENT-1 -network6 2001:DB8:5001::/96

Done

add lsn pool LSN-NAT64-POOL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

bind lsn pool LSN-NAT64-POOL-1 -ownerNode 1  203.0.113.61 - 203.0.113.70

Done

bind lsn pool LSN-NAT64-POOL-1 -ownerNode 2  203.0.113.101 - 203.0.113.110

Done

add lsn ip6profile LSN-NAT64-PROFILE-1 -type NAT64 -natprefix
2001:DB8:300::/96

Done

add lsn group LSN-NAT64-GROUP-1 -clientname LSN-NAT64-CLIENT-1  -
ip6profile LSN-NAT64-PROFILE-1

Done

bind lsn group LSN-NAT64-GROUP-1 -poolname LSN-NAT64-POOL-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add ns acl6 NAT64-DFD ALLOW -srcIPv6 = 2001:DB8:5001:: -type DFD -dfdhash
SIP -dfdprefix 64

Done

apply ns acls6 -type DFD

Done
```

Mapping Address and Port using Translation

Mapping Address and Port using Translation (MAP-T) is an IPv6 transition solution for ISPs with IPv6 infrastructure to connect their IPv4 subscribers to the IPv4 internet `<sub>. </sub>MAP-T` is built on stateless IPv4 and IPv6 address translation technologies. MAP-T is a mechanism that performs double translation (IPv4 to IPv6 and vice versa) on customer edge (CE) devices and border routers (in ISP core network).

In a MAP-T deployment, the CE device implements a combination of stateful NAPT44 translation and stateless NAT46 translation. The CE device obtains NAT-IP and the port-block to be used for translation through DHCPv6 or any other method.

When an IPv4 packet from a subscriber device arrives at the CE device, the CE device performs NAPT44 and stores the NAPT44 binding information. After NAT44 translation, the packet is subjected to NAT46 translation and then forwarded to the border router (BR) device located in the ISP's core network. The BR device receives the IPv6 packets from the CE device, extracts and validates the NAT-IP and port-block embedded in the IPv6 header, and forwards the IPv4 packet to the IPv4 Internet. When the BR receives the IPv4 packet from the Internet, it translates the IPv4 packet to an IPv6 packet and send the IPv6 packet to the CE device.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

MAP-T is stateless on a BR device, so it does not require the BR device to perform NAT on the traffic. Instead, NAT functionality is delegated to the CE devices. This delegation and stateless functionality in BR devices allows the BR deployment to scale in proportion to the volume of traffic.

The NetScaler appliance implements the BR functionality of a MAP-T solution as described by RFC 7599.

Configuring MAP-T

Configuring MAP-T on a NetScaler appliance consists of the following tasks:

- Add a default mapping rule
- Add a basic mapping rule
- Bind an IPv4 NAT address range of CE devices to a basic mapping rule
- Add a map domain and bind a basic mapping rule and default mapping rule to the domain

To add a default mapping rule by using the CLI

At the command prompt, type:

```
add MapDmr <name> -BRIpv6Prefix ( <ipv6_addr> | <*> )

show MapDmr <name>
```

To add a basic mapping rule by using the CLI

At the command prompt, type:

```
add MapBmr <name> -RuleIpv6Prefix <ipv6_addr> | <*>  [-psidoffset
<positive_integer>] [-EAbitLength <positive_integer>]  [-psidlength
<positive_integer>]

show MapBmr <name>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind IPv4 NAT address range of CE devices to a basic mapping rule by using the CLI

At the command prompt, type:

```
bind MapBmr <name> (-network <ip_addr>  [-netmask <netmask>])

show MapBmr <name>
```

To add a map domain by using the CLI

At the command prompt, type:

```
add MapDomain <name> -MapDmrName <string>

show MapDomain <name>
```

To bind a basic mapping rule to a map domain by using the CLI

At the command prompt, type:

```
bind MapDomain <name> -MapBmrName <string>

show MapDomain <name>
```

Sample configuration

```
add mapdmr DMR-1 -BRIpv6Prefix 2002:db8::/64
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done

add mapbmr BMR-1 -ruleIpv6Prefix 2002:db8:89ab::/48 -eAbitLength 16
-psidlength 8 -psidoffset 6

Done

bind mapbmr BMR-1 -network 192.0.1.0 -netmask 255.255.255.0

Done

add MapDomain MAP-DOMAIN-1 -mapdmrname DMR-1

Done

bind MapDomain MAP-DOMAIN-1 -mapbmrname BMR-1

Done
```

Telco subscriber management

The number of subscribers in a telco network is increasing at an unprecedented rate, and managing them is becoming a challenge for service providers. Newer, faster, and smarter devices are placing high demand on the network and the subscriber management systems. It is no longer feasible to provide each subscriber the same standard of service, and the need for traffic processing on a per-subscriber basis is imperative.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The NetScaler appliance provides the intelligence to profile subscribers based on their information stored in the Policy and Charging Rules Function (PCRF). When a mobile subscriber connects to the Internet, the packet gateway associates an IP address with the subscriber and forwards the data packet to the appliance. The appliance receives the subscriber information dynamically, or you can configure static subscribers. This information enables the appliance to apply its rich traffic management capabilities, such as content switching, integrated caching, rewrite, and responder, on a per-subscriber basis to manage the traffic.

Before you configure the NetScaler appliance to manage subscribers, you must allocate memory to the module that stores subscriber sessions. For dynamic subscribers, you must configure an interface through which the appliance receives session information. Static subscribers must be assigned IDs, and you can associate them with policies.

You can also do the following:

- Subscriber policy enforcement and management.
- Configure the appliance to uniquely identify a subscriber by using only the IPv6 prefix instead of the complete IPv6 address.
- Use policies to optimize TCP traffic for both dynamic and static subscribers. These policies associate different TCP profiles with different types of users.
- Manage idle sessions on a NetScaler appliance.
- Enable logging to a log server.
- Remove LSN sessions for deleted subscriber sessions.

Allocating memory for the subscriber session store module

Each subscriber session entry consumes 1 KB of memory. Storing 500,000 subscriber sessions at any point in time requires 500 MB of memory. This value must be added to the minimum memory requirement, which is shown as part of the output of the “show extendedmemoryparam” command. In the following example, the output is for a NetScaler VPX instance with 3 packet engines and 8 GB memory.

To store 500,000 subscriber sessions on this appliance, the configured memory must be 2058+500 MB (500,000 x 1 KB = 500 MB.)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

The configured memory must be in multiples of 2 MB and must not exceed the maximum memory usage limit. The appliance must be restarted for the changes to take effect.

Example

```
show extendedmemoryparam

       Extended Memory Global Configuration. This memory is utilized by
LSN and Subscriber Session Store Modules:

        Active Memory Usage: 0 MBytes

        Configured Memory Limit: 0 MBytes

        Minimum Memory Required: 2058 MBytes

        Maximum Memory Usage Limit: 2606 MBytes

    Done

    set extendedmemoryparam -memLimit 2558

    Done

    show extendedmemoryparam

            Extended Memory Global Configuration. This memory is utilized
by LSN and Subscriber Session Store Modules:

            Active Memory Usage: 2558 MBytes

            Configured Memory Limit: 2558 MBytes

            Minimum Memory Required: 2058 MBytes

            Maximum Memory Usage Limit: 2606 MBytes
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

Configure an interface for dynamic subscribers

The NetScaler appliance dynamically receives the subscriber information through any of the following types of interface:

- Gx Interface
- RADIUS Interface
- RADIUS and Gx Interface

NOTE

- Starting with NetScaler release 12.0 build 57.19, Gx interface is supported for a cluster deployment. For more information see Gx interface in a cluster topology.
- In an HA setup, the subscriber sessions are continually synchronized on the secondary node. In the event of a failover, the subscriber information is still available on the secondary node.

Gx interface

A Gx interface (as specified in 3GPP 29.212) is a standard interface based on the Diameter protocol that allows exchange of policy control and charging rules between a PCRF and a Policy and Charging Enforcement Function (PCEF) entity in a Telco network.

When an IP-CAN session is established, the packet gateway forwards the subscriber ID, such as the MSISDN, and Framed-IP address information about the subscriber to the PCRF as a Diameter message. When the data packet arrives at the appliance from packet gateway (PGW), the appliance uses the subscriber IP address to query the PCRF to get the subscriber information. This is also known as secondary PCEF functionality.

The Policy and Charging Control (PCC) rules received by the appliance over the Gx interface are stored on the appliance during the subscriber session, that is, until the PCRF sends a Re-Auth-Request (RAR) message with a Session-Release-Cause AVP or the subscriber session is terminated from the CLI or the configuration utility. If there are any updates to an existing

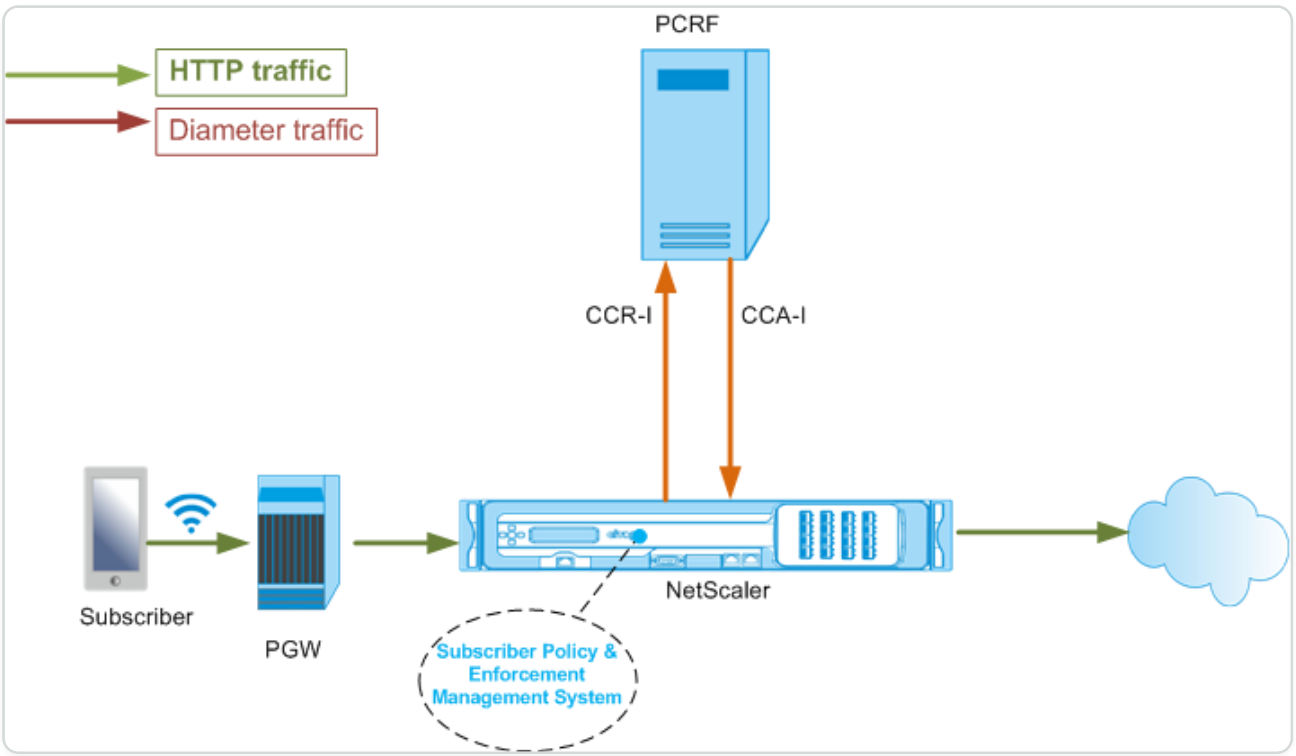
© 1997–2026 Citrix Systems, Inc. All rights reserved.

subscriber, the PCRF sends the updates in an RAR message. A subscriber session is initiated when a subscriber logs on to the network, and terminated when the subscriber logs off.

NOTE

. If the PCRF server is down, the NetScaler appliance creates negative sessions for the pending or incoming Gx subscriber requests. When the PCRF server is back up again, the NetScaler appliance prevents a storm of requests by waiting for the negative sessions to expire before performing the specific subscriber requests.

The following illustration shows the high-level traffic flow. It assumes that the data plane traffic is HTTP. The appliance sends a Credit Control Request (CCR) over a Gx interface to the PCRF server and, in the credit control answer (CCA), receives the PCC rules and, optionally, other information, such as the Radio Access Technology (RAT) type, that applies to the particular subscriber. PCC rules include one or more policy (rule) names and other parameters. The appliance uses this information to retrieve the predefined rules stored on the appliance, and to direct the flow of traffic. It also stores this information in the subscriber policy and enforcement management system during the subscriber session. After a subscriber session is terminated, the appliance discards all the information about the subscriber.



The following example shows the commands for configuring a Gx interface. The commands are in boldface.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To set up a Gx interface, perform the following tasks

Add a DIAMETER service for each Gx interface. For example:

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868

add service pcrf-svc2 203.0.113.2 DIAMETER 3868
```

Add a non-addressable DIAMETER load balancing virtual server and bind the services created in step 1 to this virtual server. For more than one service, specify a persistenceType and the persistAVPno so that specific sessions are handled by the same PCRF server. For example:

```
add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
-persistAVPno 263

bind lb vserver vdiam pcrf-svc1

bind lb vserver vdiam pcrf-svc2
```

Configure NetScaler diameter identity and realm. Identity and realm are used as Origin-Host and Origin-Realm AVPs in diameter messages sent by the Gx client. For example:

```
set ns diameter –identity netscaler.com –realm com
```

Configure the Gx interface to use the virtual server created in step 2 as the PCRF virtual server. Specify the PCRF realm to use as Destination-Realm AVP in diameters messages sent by the Gx client. For example:

```
set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf.com
```

Set the subscriber interface type to GxOnly. For example:

```
set subscriber param -interfaceType GxOnly
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To see the Gx interface configuration and status, type:

```
show subscriber gxinterface
```

Example

```
show subscriber gxinterface

    Gx Interface parameters:

        PCRF Vserver: vdiam (DOWN)

        Gx Client Identity...:  netscaler1.com

        Gx Client Realm ..........:  com

        PCRF Realm: epc.mnc030.mcc234.3gppnetwork.org

        Hold Packets On Subscriber Absence: YES

        CCR Request Timeout: 4 Seconds

        CCR Request Retry Attempts: 1

        Gx HealthCheck enabled: NO

        Gx HealthCheck TTL : 30 Seconds

        CER Request Timeout: 10 Seconds

        RevalidationTimeout: 30 Seconds

        NegativeTTL: 60 Seconds

        NegativeTTL Limited Success: NO

        Purge SDB on Gx Failure: YES

        ServicePath AVP code: 262099    ServicePath AVP VendorID: 3845

        PCRF Connection State: PCRF is not ready
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done
```

ARGUMENTS

vServer

Name of the load balancing or content switching virtual server to which the Gx connections are established. The service type of the virtual server must be DIAMETER or SSL_DIAMETER. This parameter is mutually exclusive with the service parameter. Therefore, you cannot set both service and the virtual server in the Gx interface.

Service

Name of DIAMETER or SSL_DIAMETER service corresponding to PCRF to which the Gx connection is established. This parameter is mutually exclusive with the vserver parameter. Therefore, you cannot set both service and the virtual server in the Gx Interface.

pcrfRealm

The realm of PCRF to which the message is to be routed. This is the realm used in Destination-Realm AVP by NetScaler Gx client (as a Diameter node).

holdOnSubscriberAbsence

Set to Yes to hold packets until the subscriber session information is fetched from the PCRF server. If set to No, the default subscriber profile is applied until the subscriber session information is fetched from the PCRF server. If a default subscriber profile is not configured, an UNDEF is raised for expressions that use subscriber attributes.

requestTimeout

Time, in seconds, within which the Gx CCR request must complete. If the request does not complete within this time, the request is retransmitted for the number of times specified in the requestRetryAttempts parameter. If request is not complete even after retransmitting, then the default subscriber profile is applied to this subscriber. If a default subscriber profile is not

© 1997–2026 Citrix Systems, Inc. All rights reserved.

configured, an UNDEF is raised for expressions that use subscriber attributes. Zero disables the timeout. Default value: 10

requestRetryAttempts

Specify the number of times a request must be retransmitted if the request does not complete within the value specified in the requestTimeout parameter. Default value: 3.

healthCheck

Set to Yes to enable inline health check of Gx peer. When enabled, NetScaler sends DWR packets to the PCRF server. When the Gx session is idle, the healthCheck timer expires and DWR packets are initiated to check if the PCRF server is active. Default value: No. **Note:** This parameter is supported in NetScaler 12.1 build 51.xx and later.

healthCheckTTL

Time in seconds defined for watchdog supervision. After the health check TTL time expires, DWR is sent to check the status of the PCRF server. Any CCR, CCA, RAR, or RAA message resets the timer. Minimum value: 6 seconds. Default value: 30 seconds. **Note:** This parameter is supported in NetScaler 12.1 build 51.xx and later.

cerRequestTimeout

Time in seconds defined for retransmission of the capabilities exchange request. NetScaler initiates a new CER message if it does not receive a CEA from the PCRF within this configured time. If no response is received from the PCRF server, the appliance tries to send the CER message 5 times. If there is no response even after 5 CER messages, the appliance closes the TCP connection and reports a failure. If the timeout value is set to 0, the application health check feature is disabled. Minimum value: 0 seconds. Default value: 0 seconds. **Note:** This parameter is supported in NetScaler 12.1 build 51.xx and later.

revalidationTimeout

Time, in seconds, after which the Gx CCR-U request is sent after any PCRF activity on a session. Any RAR or CCA message resets the timer. Zero value disables the idle timeout.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

negativeTTL

Time, in seconds, after which the Gx CCR-I request is resent for sessions that have not been resolved by PCRF because the server is down or there is no response or a failed response is received. Instead of polling the PCRF server constantly, a negative-TTL makes the appliance hold on to an unresolved session. For negative sessions, the appliance inherits the attributes from the default subscriber profile, if one is configured and from the RADIUS accounting message, if one is received. Zero value disables the negative sessions. The appliance does not install negative sessions even if a subscriber session could not be fetched. Default value: 600

negativeTTLLimitedSuccess

Set to Yes to create negative session for partial success response code (2002). If set to No, regular session is created. Default value: No.

This parameter is supported in NetScaler 12.1 build 49.xx and later.

purgeSDBonGxFailure

Set to Yes to flush subscriber database when the Gx interface fails. Gx interface failure includes both DWR monitoring (if enabled) and network healthCheck (if enabled). When set to Yes, all subscriber sessions are cleared. Default value: No. **Note:** This parameter is supported in NetScaler 12.1 build 51.xx and later.

servicePathAVP

The AVP code in which PCRF sends the service path applicable to a subscriber.

servicePathVendorid

The vendor id of the AVP in which PCRF sends the service path applicable to a subscriber.

To configure Gx interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **GxOnly**.
4. Specify the values for the all required parameters.
5. Click **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Detect transport failures over established Gx connections

Note: This feature is supported in NetScaler 12.1 build 51.xx and later.

A NetScaler appliance can be configured to detect transport failures over established Gx connections by using device watchdog request (DWR) and device watchdog answer (DWA) messages.

After a Gx session is established, a predefined timer is triggered to detect if a session is idle. A DWR message is sent after the idle time timer expires. The idle time timer is reset each time the NetScaler appliance receives a message over an established Gx session. The peer's availability is confirmed based on the DWA message after a DWR message is sent.

- If the DWA is received, a peer's availability is confirmed and the watchdog timer is reset.
- If the DWA is not received and the watchdog timer expires twice consecutively, the session is considered as down and peer unavailable. The appliance closes the session and tries to establish a new session with the Gx peer.

When the watchdog timer expires twice without a response, the NetScaler appliance considers the Gx connection as faulty and initiates a connection closure. Once the connection is closed, no other watchdog request is sent towards the Gx peer. NetScaler appliance uses the next available Gx session for any PCRF requests.

To detect transport failures over established Gx connections by using the CLI

At the command prompt, type:

```
set subscriber gxInterface [-vServer <string>] [-service <string>] [-
healthCheck ( YES | NO )] [-healthCheckTTL<positive_integer>][-
cerRequestTimeout <positive_integer>] [-purgeSDBonGxFailure ( YES | NO )]
```

Example:

```
set subscriber gxInterface set subscriber gxInterface -vServer vdiam
-healthCheck YES -healthCheckTTL 31 -cerRequestTimeout 15
purgeSDBonGxFailure  YES
```

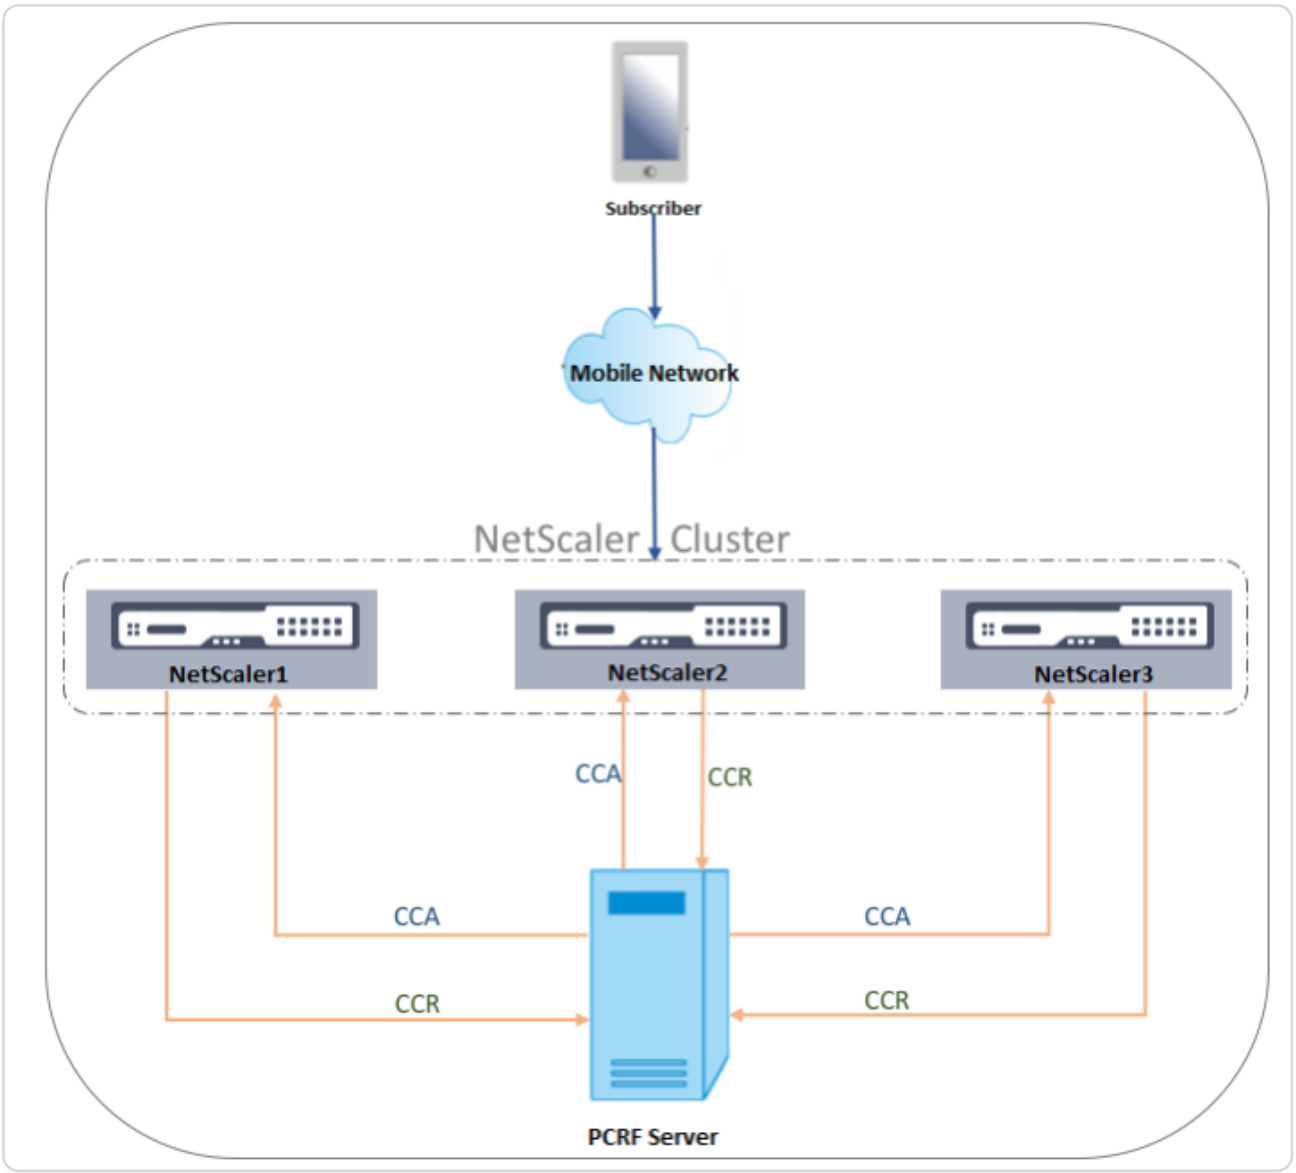
© 1997–2026 Citrix Systems, Inc. All rights reserved.

To detect transport failures over established Gx connections by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In **Interface Type**, select **GxOnly**.
4. Specify the values for all required parameters.
5. Select **Health Check** and specify values for **Health Check TTL** and **CER Request Timeout**.
6. Click **OK**.

Gx interface in a cluster topology

The NetScaler appliance supports Gx interface in a cluster topology.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

The NetScaler nodes in the cluster communicate with an external PCRF server through the Gx interface. When a node receives client traffic, the appliance performs the following:

- Sends a CCR-I request to the PCRF server to fetch subscriber information.
- The PCRF server responds with a CCR-A.
- The NetScaler node then stores the received subscriber information in its subscriber store and applies the rules to the client traffic.

Each node maintains an independent subscriber store and subscriber sessions are not synchronized to other nodes.

As per the Diameter Base Protocol RFC 6733, each peer must be configured with a unique diameter identity to communicate with other peers over the diameter protocol. Hence, in a cluster deployment, configuration of diameter identity is spotted. The diameter parameters (identity, realm, server close propagation) for each node can be configured individually by using the GUI or the CLI.

When a node is added to a cluster, it assumes the default diameter parameters (identity=netscaler.com, realm=com, serverClosePropogation=NO). After the nodes are added, the diameter parameters for each node must be configured.

To configure the diameter parameters by using the GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Change Diameter Parameters**.
3. In the Diameter Parameters page, select the NetScaler node for which you want to configure the diameter parameters and then click **Configure**.
4. In the Configure Diameter Parameters page, configure the diameter Identity, diameter Realm, and server Close Propagation for the selected node.
5. Click **OK**.

To configure the diameter parameters by using the CLI

At the command prompt, type:

```
set ns diameter [-identity <string>] [-ownerNode <positive_integer>]
```

ARGUMENTS

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Identity

Diameter Identity is used to identify a Diameter node uniquely. Before setting up diameter configuration, the NetScaler appliance (as a Diameter node) must be assigned a unique diameter identity.

For example, set ns diameter -identity netscaler.com -ownerNode 1. So, whenever NetScaler system needs to use identity in diameter messages, it uses 'netscaler.com' as Origin-Host AVP as defined in RFC3588.

Maximum Length: 255

OwnerNode

OwnerNode represents the ID of the cluster node for which the diameter ID is set. OwnerNode can be configured only through CLIP.

Minimum value: 0

Maximum value: 31

Example:

set ns diameter -identity netscaler1.com -ownerNode 1

Note:

The OwnerNode option is also added to the show ns diameter command.

Example:

```
show diameter -ownerNode <0-31>
```

When the show ns diameter command is executed, it displays the diameter parameters for a given node.

To configure a Gx interface for cluster deployment

To set up a Gx interface, perform the following tasks:

Add a DIAMETER service for each Gx interface.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868

add service pcrf-svc2 203.0.113.2 DIAMETER 3868
```

Add a DIAMETER load balancing virtual server and bind the services created in step 1 to this virtual server.

Example:

```
add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
-persistAVPno 263

bind lb vserver vdiam pcrf-svc1

bind lb vserver vdiam pcrf-svc2
```

Configure NetScaler diameter identity and realm on all the cluster nodes. Identity and realm are used as Origin-Host and Origin-Realm AVPs in diameter messages sent by the Gx client.

Example:

```
set ns diameter -identity node0.netscaler.com -realm netscaler.com
-ownerNode 0

set ns diameter -identity node1.netscaler.com -realm netscaler.com
-ownerNode 1
```

Configure the Gx interface to use the virtual server created in step 2 as the PCRF virtual server and set the PCRF realm as well.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf.com

Set the subscriber interface type to GxOnly.
```

Example:

```
set subscriber param -interfaceType GxOnly
```

To see the Gx interface configuration and status, type:

```
show subscriber gxinterface
```

RADIUS interface

With a RADIUS interface, the packet gateway forwards the subscriber information in a RADIUS Accounting Start message to the appliance through the RADIUS interface when an IP-CAN session is established. A service of type RADIUSListener processes RADIUS Accounting messages. Add a shared secret for the RADIUS client. If a shared secret is not configured, the RADIUS message is silently dropped. The following example shows the commands for configuring a RADIUS interface. The commands are in boldface.

To set up a RADIUS interface, perform the following tasks:

Create a RADIUS listener service at the SNIP address where the RADIUS messages are received. For example:

```
add service srad1 192.0.0.206 RADIUSLISTENER 1813
```

Configure the subscriber RADIUS interface to use this service. For example:

```
set subscriber radiusInterface -listeningService srad1
```

Set the subscriber interface type to RadiusOnly. For example:

```
set subscriber param -interfaceType RadiusOnly
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add a RADIUS client specifying a subnet and shared secret. For example:

```
add radius client 192.0.2.0/24 -radkey client123
```

A subnet of 0.0.0.0/0 implies that it is the default shared secret for all clients. To see the RADIUS interface configuration and status, type:

```
show subscriber radiusInterface
```

RADIUS Interface parameters:

Radius Listener Service: srad1(UP)

Done

Example:

```
add service pcrf-svc1 203.0.113.1 DIAMETER 3868

add service pcrf-svc2 203.0.113.2 DIAMETER 3868
```

ARGUMENTS

ListeningService

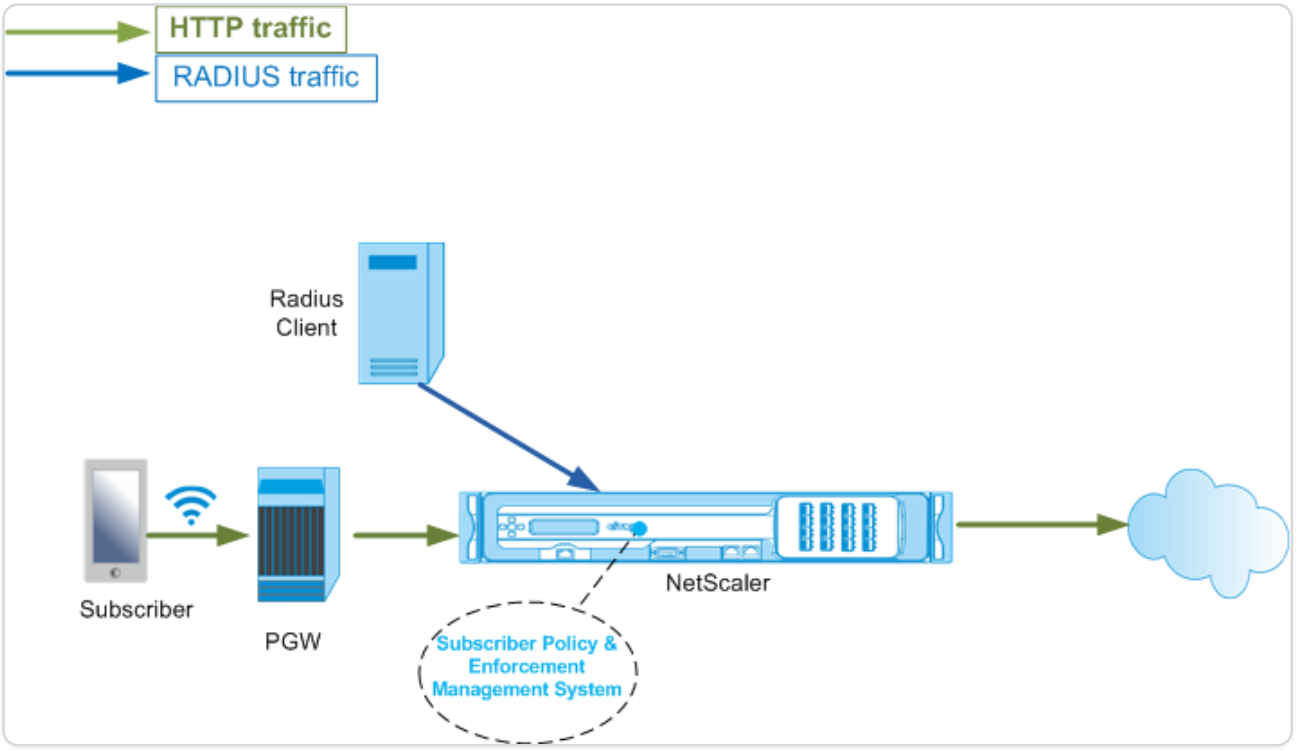
Name of the RADIUS listening service that processes the RADIUS accounting requests.

svrState

The state of the RADIUS listening service.

The following illustration shows the high-level traffic flow.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



To configure RadiusOnly interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **RadiusOnly**.
4. Specify the values for the all required parameters.
5. Click **OK**.

RADIUS and Gx interface

With a RADIUS and Gx interface, when an IP-CAN session is established, the packet gateway forwards the subscriber ID, such as the MSISDN, and Framed-IP address information about the subscriber to the appliance through the RADIUS interface. The appliance uses this subscriber ID to query the PCRF on the Gx interface to get the subscriber information. This is known as primary PCEF functionality. The following example shows the commands for configuring a RADIUS and Gx interface.

```
set subscriber param -interfaceType RadiusandGx

add service pcrf-svc 203.0.113.1 DIAMETER 3868

add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

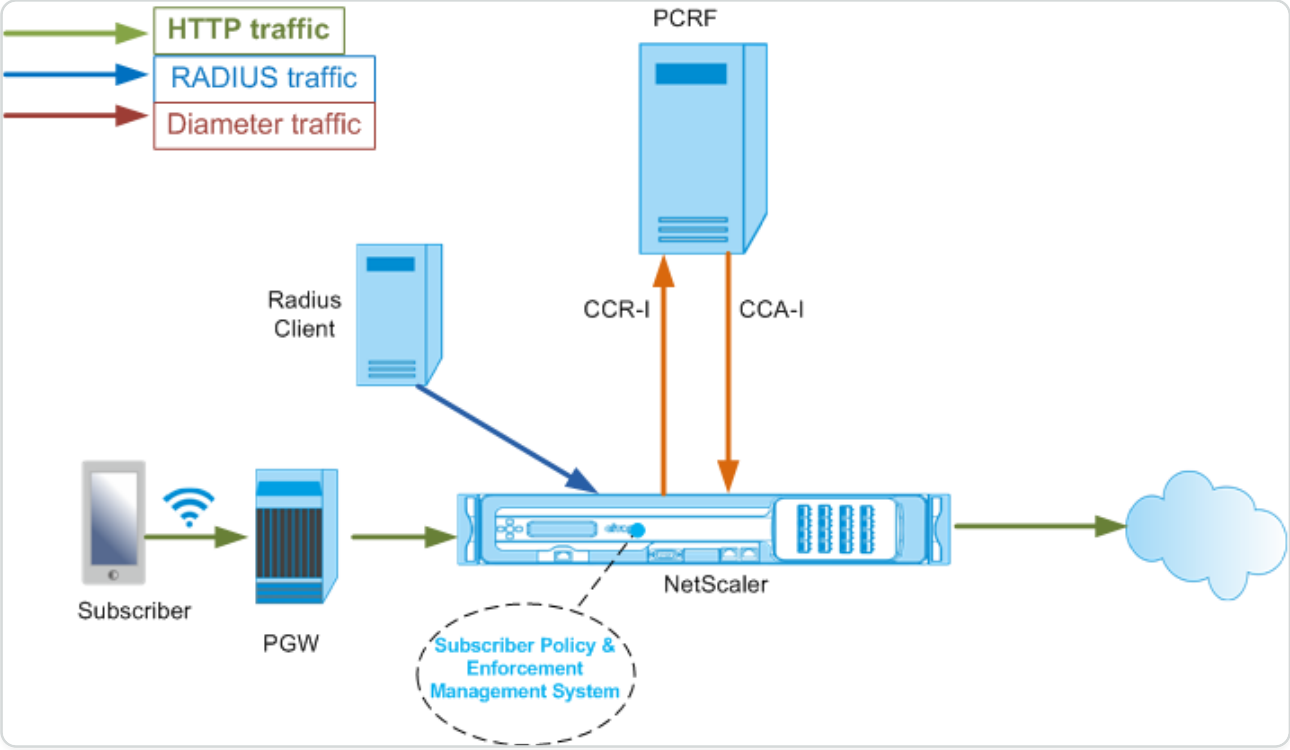
```
-persistAVPno 263

bind lb vserver vdiam pcrf-svc

set subscriber gxInterface -vServer vdiam -pcrfRealm testrealm1.net
-holdOnSubscriberAbsence YES -revalidationTimeout 60 -negativeTTL 120

add service srad1 192.0.0.206 RADIUSLISTENER 1813    set subscriber
radiusInterface -listeningService srad1
```

The following illustration shows the high-level traffic flow.



To configure RadiusAndGx interface by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. Click **Configure Subscriber Parameters**.
3. In Interface Type, select **RadiusAndGx**.
4. Specify the values for the all required parameters.
5. Click **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure static subscribers

You can configure the subscribers manually on the NetScaler appliance by using the command line or the configuration utility. You create static subscribers by assigning a unique subscriber ID and optionally associating a policy with each subscriber. The following examples show the commands for configuring a static subscriber.

In the following examples, **subscriptionIdvalue** specifies the international telephone number, and **subscriptionIdType** (E164 in this example) specifies the general format for international telephone numbers.

```
add subscriber profile 203.0.113.6 -subscriberRules policy1 policy2
-subscriptionIdType E164 -subscriptionIdvalue 98767543211

add subscriber profile 2002::a66:e8d3/64 -subscriberRules policy1 policy3
-subscriptionIdtype E164 -subscriptionIdvalue 98767543212

add subscriber profile 203.0.24.2 10 -subscriberRules policy2 policy3
-subscriptionIdtype E164 -subscriptionIdvalue 98767543213
```

To view the configured subscriber profiles, type:

show subscriber profile

```
    > show subscriber profile

    1)  Subscriber IP: 203.0.24.2 VLAN:10

        Profile Attributes:

                Active Rules: policy2, policy3

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543213

    2)  Subscriber IP: 2002::/64

        Profile Attributes:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                Active Rules: policy1, policy3

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543212

    3)  Subscriber IP: 203.0.113.6

        Profile Attributes:

                Active Rules: policy1, policy2

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543211

     Done
```

Default subscriber profile

A default subscriber profile is used if the subscriber IP address is not found in the subscriber session store on the appliance. In the following example, a default subscriber profile is added with the subscriber rule policy1.

```
> add subscriber profile * -subscriberRules policy1
```

View and clear subscriber sessions

Use the following command to display all the static and dynamic subscriber sessions.

show subscriber sessions

```
    > show subscriber sessions

    1)  Subscriber IP: 2002::/64

        Session Attributes:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                Active Rules: policy1, policy3

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543212

    2)  Subscriber IP: *

        Session Attributes:

                Active Rules: policy1

    3)  Subscriber IP: 203.0.24.2 VLAN:10

        Session Attributes:

                Active Rules: policy2, policy3

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543213

    4)  Subscriber IP: 203.0.113.6

        Session Attributes:

                Active Rules: policy1, policy2

                Subscriber Id Type: E164

                Subscriber Id Value: 98767543211

    5)  Subscriber IP: 192.168.0.11

        Session Attributes:

                Idle TTL remaining: 361 Seconds

                Active Rules: policy1

                Subscriber Id Type: E164

                Subscriber Id Value: 1234567811
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
                Service Path: policy1

                AVP(44): 34 44 32 42 42 38 41 43  2D 30 30 30 30 30 30 31
31

                AVP(257): 00 01 C0 A8 0A 02

                PCRF-Host: host.pcrf.com

                AVP(280): 74 65 73 74 2E 63 6F 6D

    Done
```

Use the following command to clear a single session or the complete session store. If you do not specify an IP address, the complete subscriber session store is cleared.

```
clear subscriber sessions <ip>
```

Subscriber policy enforcement & management system

The NetScaler appliance uses the subscriber's IP address as the key to the subscriber policy enforcement and management system.

You can add subscriber expressions to read the subscriber information available in the Subscriber Policy Enforcement & Management System. These expressions can be used with policy rules and actions that are configured for NetScaler features, such as integrated caching, rewrite, responder, and content switching.

The following commands are an example of adding a subscriber-based responder action and policy. The policy evaluates to true if the subscriber rule value is“pol1.”

```
add responder action error_msg respondwith '"HTTP/1.1 403 OKrnrn" + " You
are  not authorized to access Internet"'

add responder policy no_internet_access "SUBSCRIBER.RULE_ACTIVE("pol1")"
error_msg
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following example shows the commands to add a subscriber-based rewrite action and policy. The action inserts an HTTP header “X-Nokia-MSISDN” by using the value of AVP(45) in the subscriber session.

```
> add rewrite action AddHDR-act insert_http_header X-Nokia-MSISDN
"SUBSCRIBER.AVP(45).VALUE"

> add rewrite policy AddHDR-pol
"HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).EQUALS_ANY("patset-test")" AddHDR-
act
```

In the following example, two policies are configured on the appliance. When the appliance checks the subscriber information and the subscriber rule is cache_enable, it performs caching. If the subscriber rule is cache_disable, the appliance does not perform caching.

```
> add cache policy nocachepol -rule
"SUBSCRIBER.RULE_ACTIVE("cache_disable")" - action NOCACHE

> add cache policy cachepol -rule "SUBSCRIBER.RULE_ACTIVE("cache_enable")"
- action CACHE -storeInGroup cg1
```

For a complete list of expressions starting with “SUBSCRIBER.” see the Policy Configuration Guide.

IMPORTANT

NetScaler software release 12.1 supports IPANDVLAN key lookup method when the subscriber interface is set to GxOnly. For details, see IP address and VLAN ID key lookup method.

IPv6 prefix based subscriber sessions

A telco user is identified by the IPv6 prefix rather than the complete IPv6 address. The NetScaler appliance now uses the prefix instead of the complete IPv6 address (/128) to identify a subscriber in the database (subscriber store). For communicating with the PCRF server (for example, in a CCR-I message), the appliance now uses the framed-IPv6-Prefix AVP instead of the complete IPv6 address. The default prefix length is /64, but you can configure the appliance to use a different value.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure the IPv6 prefix by using the command line

```
set subscriber param [-ipv6PrefixLookupList <positive_integer> ...]
```

The first example command below sets a single prefix and the second example command sets multiple prefixes.

```
set subscriber param -ipv6PrefixLookupList 64

set subscriber param -ipv6PrefixLookupList 64 72 96
```

To configure the IPv6 prefix by using the configuration utility

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. In the details pane, under **Settings**, click **Configure Subscriber Parameters** and in **IPv6 Prefix Lookup List**, specify one or more prefixes.

IP address and VLAN ID key lookup method

The NetScaler appliance uses the subscriber's IP address as the key lookup method to the subscriber policy enforcement and management system. This method is not effective if the IP addresses are overlapping. In such cases, you can use the VLAN ID as an additional subscriber lookup type. IPANDVLAN key lookup method is supported only when the subscriber interface is set to GxOnly. When IPANDVLAN is configured as the lookup method, the NetScaler appliance performs the following:

- Includes the originating VLAN ID in the Gx query for IPv4 subscribers.
- Includes the Gx VLAN AVP in all Gx responses. However, if there is a VLAN ID mismatch, the appliance ignores the responses.

For example, if the appliance sends a CCR-I with GxSessionId-a:IPv4-b:VLAN-c and the response contains GxSessionId-a:IPv4-b:VLAN-d, the response is dropped and a default subscriber entry is created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

- Interface type RadiusAndGx and RadiusOnly cannot be configured together with key type IPANDVLAN.
- If the traffic is from an IPv6 address, the NetScaler appliance uses the IP lookup method.

To configure IP or IPANDVLAN as the key lookup method by using the CLI

At the command prompt, type:

```
set subscriber param [-keytype ( IP | IPANDVLAN )] [-interfaceType
<interfaceType>]
```

Example:

```
set subscriber param -keytype IPANDVLAN -interfaceType GxOnly

set subscriber param -keytype IP -interfaceType GxOnly
```

NOTE

Changing the keytype parameter from IP to IPANDVLAN and conversely clears all subscriber data.

VLAN parameter

The VLAN parameter is also added for the following commands.

```
add subscriber profile <ip>@ [-vlan]

set subscriber profile <ip>@ [-vlan] [-subscriptionIdType
 <subscriptionIdType>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show subscriber profile [<ip>@] [-vlan]

rm subscriber profile <ip>@ [-vlan <positive_integer>]
```

Arguments

ip

Represents the subscriber IP address. This is a mandatory argument and cannot be changed after the subscriber profile is added.

vlan

Represents the VLAN number on which the subscriber is located. The VLAN number cannot be changed after the subscriber profile is added.

Minimum value: 1

Maximum value: 4096

```
add subscriber profile 192.0.2.23 10

set subscriber profile 192.0.2.23 10 -subscriptionIdtype E164

show subscriber profile 192.0.2.23 10

rm subscriber profile 192.0.2.23 10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure IP or IPANDVLAN as the key lookup method by using the GUI

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters.**
2. Click **Configure Subscriber Parameters.**
3. In **Key Type**, select **IP** or **IPANDVLAN** as per your requirement.
4. Complete the configuration and click **OK**.

Idle session management of subscriber sessions in a Telco network

Subscriber session cleanup on a NetScaler appliance is based on control plane events, such as a RADIUS Accounting Stop message, a Diameter RAR (session release) message, or a "clear subscriber session" command. In some deployments, the messages from a RADIUS client or a PCRF server might not reach the appliance. Also, during heavy traffic, the messages might be lost. A subscriber session that is idle for a long time continues to consume memory and IP resources on the NetScaler appliance. The idle session management feature provides configurable timers to identify idle sessions, and cleans up these sessions based on the specified action.

A session is considered idle if no traffic from this subscriber is received on the data plane or the control plane. You can specify an update, terminate (inform PCRF and then delete the session), or delete (without informing PCRF) action. The action is taken only after the session is idle for the time specified in the idle timeout parameter.

To configure the idle session timeout and the associated action by using the command line

```
set subscriber param [-idleTTL <positive_integer>] [-idleAction
<idleAction>]
```

Examples:

```
set subscriber param -idleTTL 3600 -idleAction ccrTerminate
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set subscriber param -idleTTL 3600 -idleAction ccrUpdate

set subscriber param -idleTTL 3600 -idleAction delete
```

To disable the idle session timeout, set the idle timeout to zero.

set subscriber param –idleTTL 0

To configure the idle session timeout and the associated action by using the configuration utility

1. Navigate to **Traffic Management** > **Subscriber** > **Parameters**.
2. In the details pane, under **Settings**, click **Configure Subscriber Parameters** and specify an **Idle Time** and **Idle Action**.

Subscriber session event logging

If you enable subscriber logging, you can track the RADIUS and Gx control plane messages specific to a subscriber, and use the historical data to analyze subscriber activities. Some of the key attributes are MSISDN and time stamp. The following attributes are also logged:

- Session Event (Install, Update, Delete, Error)
- Gx Message Type (CCR-I, CCR-U, CCR-T, RAR)
- Radius Message Type (Start, Stop)
- Subscriber IP
- SubscriberID Type (MSISDN(E164), IMSI)
- SubscriberID value

By using these logs, you can track users by IP address and, if available, MSISDN.

You can enable subscriber session logging to a local or remote syslog or nslog server. The following example shows how to enable subscriber logging to a remote syslog server.

```
> add syslogAction sysact1 192.0.2.0 -loglevel EMERGENCY ALERT CRITICAL
ERROR WARNING NOTICE INFORMATIONAL -subscriberlog enabled
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

From these logs, you can learn about any activity related to a user, such as the time when a session was updated, deleted, or created (installed). Additionally, error messages are also logged.

Examples:

1. The following log entries are examples of RADIUSandGx session creation, session update, and session deletion.

   09/30/2015:16:29:18 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 147 0 : Session Install, GX MsgType: CCR-I, RADIUS MsgType: Start, IP: 100.10.1.1, ID: E164 - 30000000001

   09/30/2015:16:30:18 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 148 0 : Session Update, GX MsgType: CCR-U, IP: 100.10.1.1, ID: E164 - 30000000001

   09/30/2015:17:27:56 GMT Informational 0-PPE-0 : default SUBSCRIBER SESSION_EVENT 185 0 : Session Delete, GX MsgType: CCR-T, RADIUS MsgType: Stop, IP: 100.10.1.1, ID: E164 - 30000000001

2. The following log entries are examples of failure messages, such as when a subscriber is not found on the PCRF server and when the appliance cannot connect to the PCRF server.

   09/30/2015:16:44:15 GMT Error 0-PPE-0 : default SUBSCRIBER SESSION_FAILURE 169 0 : Failure Reason: PCRF failure response, GX MsgType: CCR-I, IP: 100.10.1.1

   Sep 30 13:03:01 09/30/2015:16:49:08 GMT 0-PPE-0 : default SUBSCRIBER SESSION_FAILURE 176 0 : Failure Reason: Unable to connect to PCRF, GX MsgType: CCR-I, RADIUS MsgType: Start, IP: 100.10.1.1, ID: E164 - 30000000001#000#000#000#000#000#000#000#000#000#000#000#000#000#000#000#000

Subscriber aware LSN session termination

In earlier releases, if a subscriber session is deleted when a RADIUS Accounting STOP or a PCRF-RAR message is received, or as a result of any other event, such as TTL expiry or flush, the corresponding LSN sessions of the subscriber are removed only after the configured LSN timeout period. LSN sessions that are kept open until this timeout expires continue to consume resources on the appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

From release 11.1, a new parameter (subscrSessionRemoval) is added. If this parameter is enabled, and the subscriber information is deleted from the subscriber database, LSN sessions corresponding to that subscriber are also removed. If this parameter is disabled, the subscriber sessions are timed out as specified by the LSN timeout settings.

To configure subscriber aware LSN session termination by using the CLI

At the command prompt, type:

set lsn parameter -subscrSessionRemoval (ENABLED | DISABLED)

```
> set lsn parameter -subscrSessionRemoval ENABLED

Done

> sh lsn parameter

            LSN Global Configuration:

            Active Memory Usage: 0 MBytes

            Configured Memory Limit: 0 MBytes

            Maximum Memory Usage Limit: 912 MBytes

            Session synchronization: ENABLED

            Subscriber aware session removal: ENABLED
```

To configure subscriber aware LSN session termination by using the GUI

1. Navigate to **System** > **Large Scale NAT**.
2. In **Getting started**, click **Set LSN Parameter**.
3. Set the **Subscriber Aware Session Removal parameter**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Troubleshooting

If your deployment is not working as expected, use the following commands to troubleshoot:

- show subscriber gxinterface This command's output can include the following error messages (shown here with suggested responses):
  - Gx Interface Not Configured-Use set subscriber param command to configure the correct interface type.
  - PCRF not configured-Configure a Diameter vServer or Service on GxInterface-Use the set subscriber gx interface command to assign a Diameter virtual server or service to this interface.
  - PCRF is not ready-Check corresponding vserver/service for more details-Use the show LB vserver or show service command to check the state of the service.
  - NetScaler is waiting for CEA from PCRF-Capability negotiation between the PCRF and NetScaler might be failing. This could be an intermittent state. If it persists, check the DIAMETER settings on your PCRF server.
  - Memory is not configured to store subscriber sessions. Please use 'set extendedmemoryparam -memlimit <>'-Use the set extendedmemoryparam command to configure extended memory.
- show subscriber radiusinterface If "Not Configured" is the output of this command, use the set subscriber radiusinterface command to specify a RADIUSListener service.

If subscriber logging is enabled, you can get more detailed information from the log files.

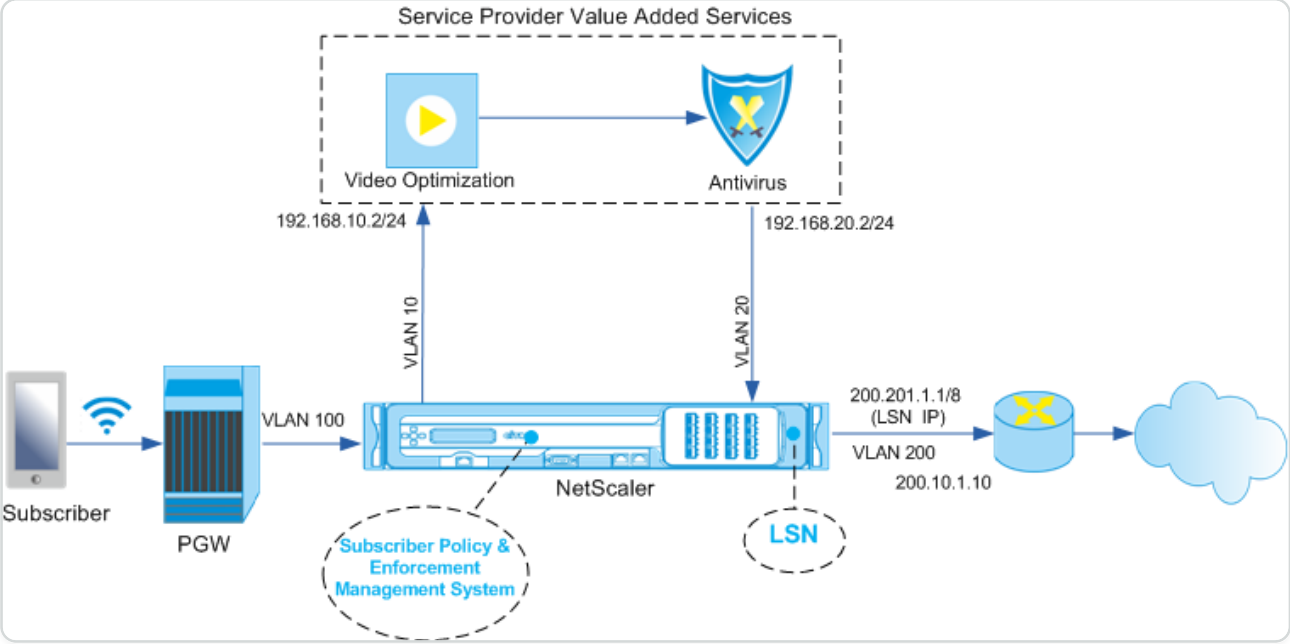
Subscriber aware traffic steering

Traffic steering directs subscriber traffic from one point to another. When a subscriber connects to the network, the packet gateway associates an IP address with the subscriber and forwards the data packet to the NetScaler appliance. The appliance communicates with the PCRF server over the Gx interface to get the policy information. Depending on the policy information, the appliance performs one of the following actions:

- Forward the data packet to another set of services (as shown in the following illustration).
- Drop the packet.
- Perform only Large Scale NAT (LSN), if LSN is configured on the appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The values shown in the following figure are configured in the CLI procedure that follows the figure. A content switching virtual server on the NetScaler appliance directs requests to the value added services or skips them, depending on the defined rule, and then sends the packet out to the Internet after performing LSN.



To configure traffic steering for the above deployment by using the CLI

Add the appliance's subnet IP (SNIP) addresses.

Example:

```
add ns ip 192.168.10.1 255.255.255.0 -type snip

add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 100.100.100.1 255.0.0.0 -type snip

add ns ip 200.200.200.1 255.0.0.0 -type snip
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add ns ip 100.1.1.1 255.0.0.0 -type snip

add ns ip 200.201.1.1 255.0.0.0 -type snip
```

Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses.

Example:

```
add vlan 10

add vlan 20

add vlan 100

add vlan 200

bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1 255.255.255.0

bind vlan 100 -ifnum 1/2 -tagged -IPAddress 100.1.1.1 255.0.0.0

bind vlan 200 -ifnum 1/3 -tagged -IPAddress 200.1.1.1 255.0.0.0
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Specify the VLAN on which the subscriber traffic arrives on the appliance. Specify the service path AVP that tells the appliance where to look for the service path name within the subscriber session. For primary PCEF functionality, specify the interfaceType as RadiusAndGx.

Example:

```
set ns param -servicePathIngressVLAN 100

set subscriber gxinterface -servicepathAVP 1001 1005 -servicepathVendorid
10415

set subscriber param -interfaceType RadiusAndGx
```

Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Then, specify the PCRF realm and subscriber Gx interface parameters. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface.

Example:

```
add service sd1 10.102.232.200 DIAMETER 3868

add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
-persistAVPno 263

bind lb vserver vdiam sd1

set ns diameter -identity netscaler.sc1.net -realm pcrf1.net

set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net
-holdOnSubscriberAbsence YES -idleTTL 1200 -negativeTTL 120
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add service srad1 10.102.232.236 RADIUSListener 1813

set subscriber radiusInterface -listeningService srad1
```

Add service functions to associate a VAS with an ingress VLAN. Add a service path to define the chain, that is, specify the VAS that the packet must be sent to and the order in which it must go to that VAS. The service path name is usually sent by the PCRF. However, the service path of the default subscriber profile (*) applies if any of the following is true:

- PCRF does not have the subscriber information.
- The subscriber information does not include this AVP.
- The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

The service path AVP that contains this name must already be configured as part of the global configuration. Bind the service function to the service path. The service index specifies the order in which the VAS is added to the chain. The highest number (255) indicates the beginning of the chain.

Example:

```
add ns servicefunction SF1 -ingressVLAN 20

add ns servicepath pol1

bind ns servicepath pol1 -servicefunction SF1 -index 255

add subscriber profile * -subscriberrules default_path
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Add the LSN configuration. That is, define the NAT pool and identify the clients for which the appliance must perform LSN.

```
add lsn pool pool1

bind lsn pool pool1 200.201.1.1

add lsn client client1

bind lsn client client1 -network 100.0.0.0 -netmask 255.0.0.0

add lsn group group1 -clientname client1

bind lsn group group1 -poolname pool1
```

The appliance performs LSN by default. To override LSN, you must create a net profile with the overrideLsn parameter enabled, and bind this profile to all the load balancing virtual servers that are configured for value added services (VASs).

Example:

```
add netprofile np1

set netprofile np1 -overrideLsn ENABLED

set lb vserver vs1 -netprofile np1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure the VAS on the appliance. This includes creating the services and virtual servers and then binding the services to the virtual servers.

```
add service vas1 192.168.10.2 ANY 80 -usip YES

add service sint 200.10.1.10 ANY 80 -usip YES

add lb vserver vs1 ANY -m MAC -l2Conn ON

add lb vserver vint ANY -m MAC -l2Conn ON

bind lb vserver vs1 vas1

bind lb vserver vint sint
```

Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The traffic arrives at the CS virtual server and is then redirected to the appropriate load balancing virtual server. Define expressions that associate a virtual server with a service function.

Example:

```
add cs vserver cs1 ANY * 80 -l2Conn ON

add cs action csact1 -targetLBVserver vs1

add cs action csactint -targetLBVserver vint
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add cs policy cspol1 -rule  SUBSCRIBER.SERVICEPATH.IS_NEXT("SF1") &&
SYS.VSERVER("vs1").STATE.EQ(UP)" -action csact1

bind cs vserver cs1 -policyName cspol1 -priority 110

bind cs vserver cs1 -lbvserver vint
```

To configure traffic steering on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to System > Network > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:
   - Interface Type: Specify **RadiusAndGx**.
   - Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
   - Specify the RADIUS interface parameters.
5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

To configure service chaining on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to System > Network > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:
   - Interface Type: Specify **RadiusAndGx**.
   - Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
   - Specify the RADIUS interface parameters.
5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Subscriber aware service chaining

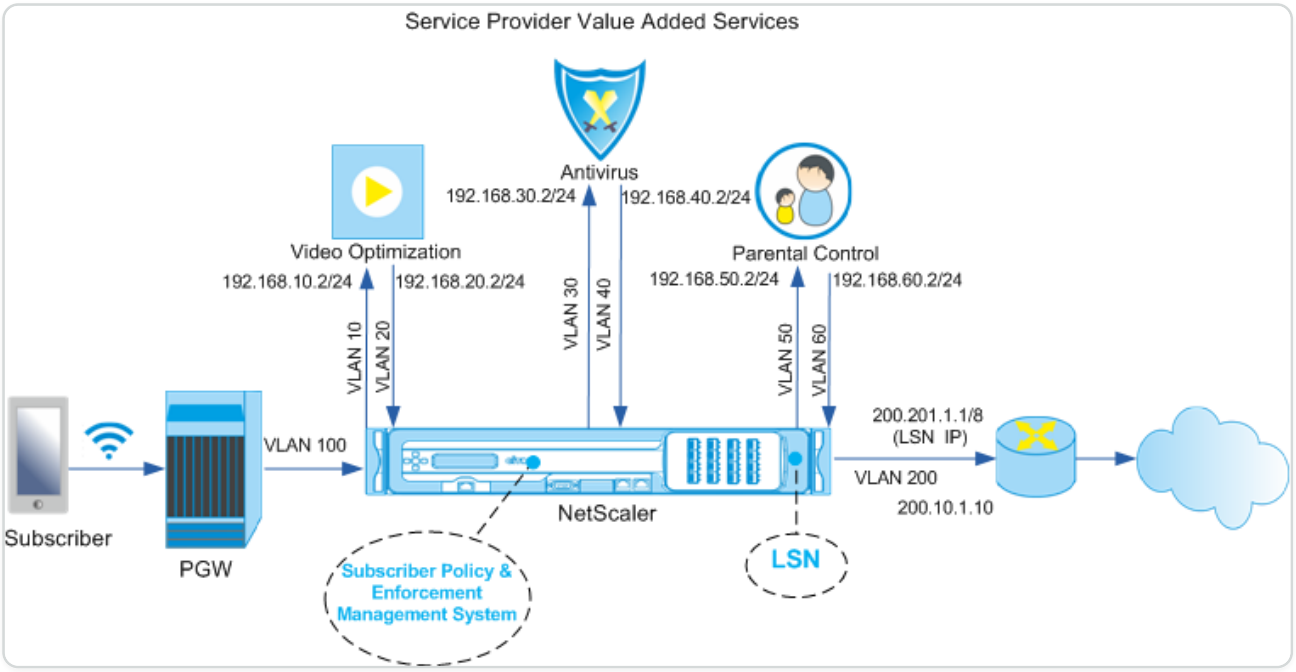
With the huge increase in the data traffic passing through telco networks, it is no longer feasible for service providers to steer all the traffic through all the value added services (VAS). A service provider should be able to optimize usage of VAS and intelligently steer traffic to improve the user experience. For example, video optimization is not required for traffic that does not include a video. Moreover, if a subscriber is connected to a 4G network, content can be streamed in high definition (HD), and video optimization might not be needed. However, video optimization improves the experience for a user in a 3G network. Similarly, caching provides a faster and better user experience and can be enabled depending on the subscriber plan. Another example of VAS is parental control. If parents provide a mobile handset to a minor child, they would like some kind of control over the websites that their child visits.

To do the above and more, service providers must be able to provide value-added services on a per-subscriber basis. In other words, entities in the service provider network must be capable of extracting the subscriber information and intelligently steering the packet on the basis of this information.

Service chaining determines the set of services through which the traffic from a subscriber must pass before going to the Internet. Instead of sending all the traffic to all the services, the NetScaler intelligently routes all requests from a subscriber to a specific set of services on the basis of the policy defined for that subscriber.

The following figure shows the entities involved in service chaining. The values shown are configured in the procedure that follows the figure. A content switching virtual server on the NetScaler appliance directs requests to the value added services or skips them, depending on the defined rule, and then sends the packet out to the Internet after performing LSN.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



To configure service chaining for the above deployment by using the CLI

Add the appliance's subnet IP (SNIP) addresses.

Example:

```
add ns ip 192.168.10.1 255.255.255.0 -type snip

add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 192.168.30.1 255.255.255.0 -type snip

add ns ip 192.168.40.1 255.255.255.0 -type snip

add ns ip 192.168.50.1 255.255.255.0 -type snip
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add ns ip 192.168.60.1 255.255.255.0 -type snip

add ns ip 100.1.1.1 255.0.0.0 -type snip

add ns ip 200.201.1.1 255.0.0.0 -type snip
```

Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses. Add an ingress and an egress VLAN for each VAS.

Example:

```
add vlan 10

add vlan 20

add vlan 30

add vlan 40

add vlan 50

add vlan 60

add vlan 100
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add vlan 200

bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.30.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.40.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.50.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.60.1 255.255.255.0

bind vlan 100 -ifnum 1/2 -tagged -IPAddress 100.1.1.1 255.0.0.0

bind vlan 200 -ifnum 1/3 -tagged -IPAddress 200.201.1.1 255.0.0.0
```

Specify the VLAN on which the subscriber traffic arrives on the appliance. Specify the service path AVP that tells the appliance where to look for the service path name within the subscriber session. For primary PCEF functionality, specify the interfaceType as RadiusAndGx.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set ns param -servicePathIngressVLAN 100

set subscriber gxinterface -servicepathAVP 1001 1005 -servicepathVendorid
10415

set subscriber param -interfaceType RadiusAndGx
```

Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Then, specify the PCRF realm and subscriber Gx interface parameters. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface.

Example:

```
add service sd1 10.102.232.200 DIAMETER 3868

add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
-persistAVPno 263

bind lb vserver vdiam sd1

set ns diameter -identity netscaler.sc1.net -realm pcrf1.net

set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net
-holdOnSubscriberAbsence YES -idleTTL 1200 -negativeTTL 120

add service srad1 10.102.232.236 RADIUSListener 1813
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set subscriber radiusInterface -listeningService srad1
```

Add service functions to associate a VAS with an ingress VLAN. Add a service path to define the chain, that is, specify the VAS that the packet must be sent to and the order in which it must go to that VAS. The service path name is usually sent by the PCRF. However, the service path of the default subscriber profile (*) applies if any of the following is true:

- PCRF does not have the subscriber information.
- The subscriber information does not include this AVP.
- The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

The service path AVP that contains this name must be configured as part of the global configuration earlier. Bind the service function to the service path. The service index specifies the order in which the VAS is added to the chain. The highest number (255) indicates the beginning of the chain.

Example:

```
add ns servicefunction SF1 -ingressVLAN 20

add ns servicefunction SF2 -ingressVLAN 40

add ns servicefunction SF3 -ingressVLAN 60

add ns servicepath pol1

bind ns servicepath pol1 -servicefunction SF1 -index 255

bind ns servicepath pol1 -servicefunction SF2 -index 254
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind ns servicepath pol1 -servicefunction SF3 -index 253

add ns servicepath pol2

bind ns servicepath pol2 -servicefunction SF2 -index 255

add ns servicepath pol3

bind ns servicepath pol3 -servicefunction SF1 -index 255

add subscriber profile * -subscriberrules default_path
```

Add the LSN configuration. That is, define the NAT pool and identify the clients for which the appliance must perform LSN.

Example:

```
add lsn pool pool1

bind lsn pool pool1 200.201.1.1

add lsn client client1

bind lsn client client1 -network 100.0.0.0 -netmask 255.0.0.0
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lsn group group1 -clientname client1

bind lsn group group1 -poolname pool1
```

The appliance performs LSN by default. To override LSN, you must create a net profile with overrideLsn parameter enabled and bind this profile to all the load balancing virtual servers that are configured for value added services (VASs).

Example:

```
add netprofile np1

set netprofile np1 -overrideLsn ENABLED

set lb vserver vs1 -netprofile np1
```

Configure the VAS on the appliance. This includes creating the services and virtual servers and then binding the services to the virtual servers.

Example:

```
add service vas1 192.168.10.2 ANY 80 -usip YES

add service vas2 192.168.30.2 ANY 80 -usip YES

add service vas3 192.168.50.2 ANY 80 -usip YES
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add service sint 200.10.1.10 ANY 80 -usip YES

add lb vserver vs1 ANY -m MAC -l2Conn ON

add lb vserver vs2 ANY -m MAC -l2Conn ON

add lb vserver vs3 ANY -m MAC -l2Conn ON

add lb vserver vint ANY -m MAC -l2Conn ON

bind lb vserver vs1 vas1

bind lb vserver vs2 vas2

bind lb vserver vs3 vas3

bind lb vserver vint sint
```

Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The traffic arrives at the CS virtual server and is then redirected to the appropriate load balancing virtual server. Define expressions that associate a virtual server with a service function.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add cs vserver cs1 ANY * 80 -l2Conn ON

add cs action csact1 -targetLBVserver vs1

add cs action csact2 -targetLBVserver vs2

add cs action csact3 -targetLBVserver vs3

add cs action csactint -targetLBVserver vint

add cs policy cspol1 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF1") &&
SYS.VSERVER("vs1").STATE.EQ(UP)" -action csact1

add cs policy cspol2 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF2") &&
SYS.VSERVER("vs2").STATE.EQ(UP)" -action csact2

add cs policy cspol3 -rule "SUBSCRIBER.SERVICEPATH.IS_NEXT("SF3") &&
SYS.VSERVER("vs3").STATE.EQ(UP)" -action csact3

bind cs vserver cs1 -policyName cspol1 -priority 110

bind cs vserver cs1 -policyName cspol2 -priority 120
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind cs vserver cs1 -policyName cspol3 -priority 130

bind cs vserver cs1 -lbvserver vint
```

To configure service chaining on the appliance by using the GUI

1. Navigate to **System** > **Network** > **IPs** and add the subnet IP addresses.
2. Navigate to **System** > **Network** > **VLANs** and add VLANs, Bind the VLANs to the interfaces and subnet IP addresses.
3. Navigate to **Traffic Management** > **Service Chaining** > **Configure Service Path Ingress VLAN** and specify an ingress VLAN.
4. Navigate to **Traffic Management** > **Subscriber** > **Parameters** > **Configure Subscriber Parameters** and specify the following:
   - Interface Type: Specify **RadiusAndGx**.
   - Configure a diameter virtual server, PCRF realm, and the subscriber GX interface parameters.
   - Specify the RADIUS interface parameters.
5. Navigate to **Traffic Management** > **Service Chaining** > **Service Function** and add service functions to associate a value-added service with an ingress VLAN.
6. Navigate to **System** > **Network** > **Large Scale NAT**. Click **Pools** and add a pool. Click **Clients** and add a client. Click **Groups** and add a group and specify the client. Edit the group and bind the pool to this group.
7. Navigate to **System** > **Network** > **Net Profiles** and add a net profile. Select **Override LSN**. Optionally, navigate to **System** > **Network** > **Settings** > **Configure Layer 3 Parameters** and verify that **Override LSN** is not selected.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** and configure the virtual servers and value-added services on the appliance. Bind the services and the net profile to the virtual server.
9. Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers** and configure a virtual server, policy, and action. Specify the target load balancing virtual server.

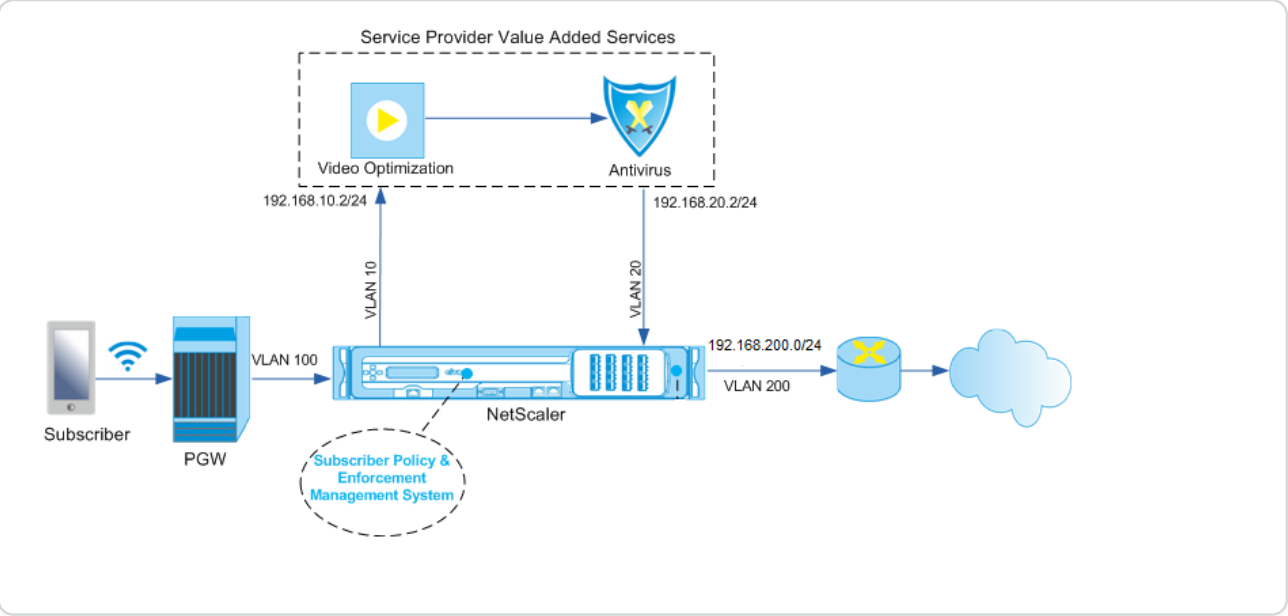
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Subscriber aware traffic steering with TCP optimization

Traffic steering directs subscriber traffic from one point to another. When a subscriber connects to the network, the packet gateway associates an IP address with the subscriber and forwards the data packet to the NetScaler appliance. The appliance communicates with the PCRF server over the Gx interface to get the subscriber policy information. Depending on the policy information, the appliance performs one of the following actions:

- Forward the data packet to another set of services (as shown in the following illustration).
- Perform only TCP optimization.

The values shown in the following figure are configured in the CLI procedure that follows the figure. A content switching virtual server on the NetScaler appliance directs requests to the value added services or skips them and performs TCP optimization, depending on the defined rule, and then sends the packet out to the Internet.



NOTE

Support for the configuration shown below was introduced in release 11.1 build 50.10.

To configure traffic steering for the above deployment by using the CLI:

1. Add the appliance's subnet IP (SNIP) addresses.

```
add ns ip 192.168.10.1 255.255.255.0 -type snip
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add ns ip 192.168.20.1 255.255.255.0 -type snip

add ns ip 192.168.100.1 255.255.255.0 -type snip

add ns ip 192.168.200.1 255.255.255.0 -type snip

add ns ip 10.102.232.236 255.255.255.0 –type snip
```

2. Add the VLANs. VLANs help the appliance identify the source of the traffic. Bind the VLANs to the interfaces and subnet IP addresses.

```
add vlan 10

add vlan 20

add vlan 100

add vlan 200

add vlan 102

bind vlan 10 -ifnum 1/4 -tagged -IPAddress 192.168.10.1 255.255.255.0

bind vlan 20 -ifnum 1/4 -tagged -IPAddress 192.168.20.1 255.255.255.0
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind vlan 100 -ifnum 1/2 -tagged -IPAddress 192.168.100.1 255.255.255.0

bind vlan 200 -ifnum 1/2 -tagged -IPAddress 192.168.200.1 255.255.255.0

bind vlan 102 –ifnum 1/1 –tagged –IPAddress 10.102.232.236
255.255.255.0
```

3. Configure a service and virtual server of type Diameter, and bind the service to the virtual server. Specify the PCRF realm and values for the subscriber Gx interface parameters. Also specify the service path AVP that indicates where the appliance can find the service path name within the subscriber session. For primary PCEF functionality, configure a RADIUS listener service and RADIUS interface, and specify the interface type as "RadiusAndGx".

```
add service sd1 10.102.232.200 DIAMETER 3868

add lb vserver vdiam DIAMETER 0.0.0.0 0 -persistenceType DIAMETER
-persistAVPno 263

bind lb vserver vdiam sd1

set ns diameter -identity netscaler.sc1.net -realm pcrf1.net

set extendedmemoryparam -memLimit 2558

set subscriber gxInterface -vServer vdiam -pcrfRealm pcrf1.net
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set subscriber gxinterface -servicepathAVP 1001 1005
-servicepathVendorid 10415

add service srad1 10.102.232.236 RADIUSListener 1813

set subscriber radiusInterface -listeningService srad1

set subscriber param -interfaceType RadiusAndGx
```

4. Specify a default subscriber profile (*) to be applied if any of the following is true:

   - PCRF does not have the subscriber information.
   - The subscriber information does not include the service path AVP.
   - The appliance is unable to query the PCRF. For example, the service representing the PCRF is DOWN.

   ```
   add subscriber profile * -subscriberrules default_path
   ```

5. Create TCP profiles for the VAS and TCP optimization path, respectively. Traffic steered to VAS will not undergo any TCP optimization before or after leaving the VAS. Therefore, the TCP mode of the VAS profile should be set to TRANSPARENT while the TCP mode of the TCPOpt profile should be set to ENDPOINT.

   add ns tcpProfile VAS –tcpMode TRANSPARENT

   add ns tcpProfile TCPOpt -WS ENABLED -SACK ENABLED -WSVal 8 -mss 1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -bufferSize 4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA ENABLED -sendBuffsize 4000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -ecn ENABLED -frto ENABLED -maxcwnd 1000000 -fack ENABLED -rstMaxAck enABLED -tcpmode ENDPOINT

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Configure load balancing for the VAS servers. Create a non-addressable virtual server of type TCP. Create TCP services with the IP addresses of the VAS servers, and bind the services to the virtual server. The virtual server and services will use the transparent TCP profile created for the VAS path:

```
add service vas1 192.168.10.2 TCP * -usip YES -useproxyport NO -TCPB NO
-tcpProfileName VAS

add service vas2 192.168.10.3 TCP * -usip YES -useproxyport NO -TCPB NO
-tcpProfileName VAS

add lb vserver vs1 TCP -m MAC -l2Conn ON –tcpProfileName VAS

bind lb vserver vs1 vas1

bind lb vserver vs1 vas2
```

7. Add a load balancing virtual server to capture VAS egress traffic. This vserver will monitor the VAS egress VLAN and will use the transparent TCP profile:

```
add lb vserver vsint TCP * * -Listenpolicy "CLIENT.VLAN.ID.EQ(20)" –
Listenpriority 30 –l2Conn ON –tcpProfileName VAS
```

8. Add a TCP optimization virtual server that listens for any traffic in the wireless-side VLAN and uses the endpoint TCP profile created for the TCP optimization path:

```
add lb vserver vs-TcpOpt TCP * * -Listenpolicy "client.vlan.id.eq(100)"
–Listenpriority 20 -l2Conn ON -tcpProfileName TCPOpt
```

9. Add the content switching (CS) configuration. This includes virtual servers, policies, and their associated actions. The CS virtual server receives the traffic and redirects it to the appropriate load balancing virtual server according to defined CS policies. Create a CS TCP virtual server

© 1997–2026 Citrix Systems, Inc. All rights reserved.

that listens for any traffic in the wireless-side VLAN with highest priority and uses the endpoint TCP profile. Create a CS policy that evaluates to TRUE when "vas" is the subscriber rule, and specify a CS action that steers traffic to VAS. Make the TCP optimization virtual server the default LB vserver. Any subscriber traffic with a rule other than "vas" will go through the default LB vserver.

```
add cs vserver cs1 TCP * * -Listenpolicy "client.vlan.id.eq(100)" –
Listenpriority 10 -l2Conn ON –tcpProfileName TCPOpt

add cs action csact1 -targetLBVserver vs1

add cs policy cspol1 -rule  SUBSCRIBER.RULE_ACTIVE(\"vas\") &&
SYS.VSERVER(\"vs1\").STATE.EQ(UP)" -action csact1

bind cs vserver cs1 -policyName cspol1

bind cs vserver cs1 -lbvserver vs-TcpOpt
```

10. Add static or policy based routes to the internet. Dynamic routing is also supported in this configuration. The following example uses policy based routes:

```
add ns pbr pbr-vlan100-to-vlan200 ALLOW -nextHop 192.168.200.10 -vlan
100 -priority 10

add ns pbr pbr-vlan20-to-vlan200 ALLOW -nextHop 192.168.200.10 -vlan 20
-priority 11

apply ns pbrs
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

- The CS policies can contain IP addresses and port numbers in addition to the subscriber expressions—for example, SUBSCRIBER.RULE_ACTIVE(\"vas\") && && (CLIENT.TCP.DSTPORT.EQ(80) || CLIENT.TCP.DSTPORT.EQ(443). They can also contain HTTP based expressions—for example, HTTP.REQ.HOSTNAME.DOMAIN.EQ(\"somedomain.com\"). In this case, replace TCP entities (vserver, service, etc.) with HTTP. The TCP profile configuration remains the same.
- Add IPv6 configuration (addresses, routes, PBRs) to support IPv6 subscribers. Happy Eyeballs client applications will work smoothly for both VAS and TCP optimization paths.
- Add VLANs, IP addresses, PBRs and LB virtual servers in front of VAS (vs1, vs2, etc.) to support multiple subscriber flows. Modify the listen policies of CS vserver "cs1" and LB vserver "vsint" to include the additional VLANs.

Policy based TCP profile selection

You can configure the NetScaler appliance to perform TCP optimization based on subscriber attributes. For example, the appliance can select different TCP profiles at run time, based on the network to which the user equipment (UE) is connected. As a result, you can improve a mobile user's experience by setting some parameters in the TCP profiles and then using a policy to select the appropriate profile.

Create separate TCP profiles for subscribers connecting through a 4G network and for users connecting through any other network. Define a policy rule that is selected based on a subscriber parameter, such as Radio Access Technolog type (RAT-Type). In the following examples, if RAT-Type is EUTRAN, a TCP profile that supports a faster connection is selected (Example 1). For all other RAT-Type values, a different TCP profile is selected (Example 2).

For more information about radio access technology and its policy configuration, see RFC 29.212.

NOTE

The RAT-Type AVP (AVP code 1032) is of type "Enumerated" and is used to identify the radio access technology serving the UE.

The value "1004" indicates that the RAT is EUTRAN.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example 1:

```
add ns tcpProfile tcp2 -WS ENABLED -SACK ENABLED -WSVal 8 -initialCwnd 16
- oooQSize 15000 -slowStartIncr 1 -bufferSize 1000000 -flavor BIC -
dynamicReceiveBuffering DISABLED -sendBuffsize 1000000 -dsack DISABLED
-maxcwnd 4000000 -fack ENABLED -minRTO 500 -maxburst 15

add appqoe action appact2 -priority HIGH -tcpprofile tcp2

add appqoe policy apppol2 -rule
"SUBSCRIBER.AVP(1032).VALUE.GET_UNSIGNED32(0, BIG_ENDIAN).EQ(1004)"
-action appact2

bind cs vserver <name>  -policyname apppol2 -priority 20 -type request
```

Example 2:

```
add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -initialCwnd 16
- oooQSize 15000 -slowStartIncr 1 -bufferSize 150000 -flavor BIC -
dynamicReceiveBuffering DISABLED -sendBuffsize 150000 -dsack DISABLED
-maxcwnd 4000000 -fack ENABLED -minRTO 200 -maxburst 15

add appqoe action appact1 -priority HIGH -tcpprofile tcp1

add appqoe policy apppol1 -rule
"SUBSCRIBER.AVP(1032).VALUE.GET_UNSIGNED32(0, BIG_ENDIAN).NE(1004)"
-action appact1

bind cs vserver <name>  -policyname apppol1 -priority 10 -type request
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Load Balance Control-Plane Traffic that is based on Diameter, SIP, and SMPP Protocols

With the increase in control-plane traffic, the servers can become a bottleneck because the traffic is not optimally distributed among the servers. Therefore, messages must be load balanced. The NetScaler appliance supports Diameter, SIP, and SMPP load balancing.

SIP

NetScaler enables you to load balance SIP messages over UDP or over TCP (including TLS) to a group of proxy servers. NetScaler also provides Call-ID based persistence and Call-ID hash load balancing method using which you direct packets for a particular SIP session to the same load balanced SIP server. The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions are intended to be used in policies for SIP protocol that operates on a request/response basis. These expressions can be used in content switching, rate limiting, responder, and rewrite policies.

For more information, see Load Balancing a Group of SIP Servers.

SMPP

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The NetScaler appliance provides optimal distribution of messages across your servers, preventing poor performance and outages. The NetScaler appliance:

- Load balances messages originating from the server and from the client
- Monitors the health of the message centers
- Provides content switching support for the message centers
- Handles concatenated messages

Limitation: Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the NetScaler appliance responds with an error message.

For more information, see SMPP Load Balancing

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Diameter

Diameter is a base protocol with more than 50 protocols (also called applications) built over it. Therefore, the diameter traffic generated in a Telco network is high. To optimally maintain this diameter traffic, the NetScaler appliance performs load balancing, content switching, and acts as a relay agent. Additionally, the appliance offers rewrite and responder functionality. The appliance supports rate limiting of Diameter messages.

For more information, see Configuring Diameter Load Balancing.

Provide DNS Infrastructure/Traffic Services, such as, Load Balancing, Caching, and Logging for Telecom Service Providers

Telecom service providers can configure the NetScaler appliance to function as a DNS proxy. Caching of DNS records, which is an important function of a DNS proxy, is enabled by default on the NetScaler appliance. This enables the NetScaler appliance to provide quick responses for repeated translations and hence enhances the customer experience and also saves the bandwidth. The caches responses from DNS name servers. When the appliance receives a DNS query, it checks for the queried domain in its cache. If the address for the queried domain is present in its cache, the NetScaler appliance returns the corresponding address to the client. Otherwise, it forwards the query to a DNS name server that checks for the availability of the address and returns it to the NetScaler appliance. The NetScaler appliance then returns the address to the client.

For requests for a domain that has been cached earlier, the NetScaler appliance serves the Address record of the domain from the cache without querying the configured DNS server and hence saves the bandwidth.

From 11.0 release onwards, NetScaler also logs the DNS requests that it receives and also the responses that it sends to the client. Telecom service providers can use this log to:

- Audit the DNS responses to the client
- Audit DNS clients
- Detect and prevent DNS attacks
- Troubleshooting

For more information, see Domain Name System.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Provide Subscriber Load Distribution Using GSLB Across Core-Networks of a Telecom Service Provider

Scalability, high availability and performance are critical to service provider deployments. While many service providers deploy there infrastructure at a single location or multiple location, these deployments are subject to a number of inherent limitations, such as:

- If the site loses connectivity to all or part of the public Internet, it will be inaccessible to users and customers, which can have significant impact on the business.
- Users accessing the site from geographically distant locations may experience large and highly variable delays, which are exacerbated by the large number of round trips that HTTP requires to transfer content.

NetScaler appliance's Global Server Load Balancing (GSLB) overcomes these problems by distributing traffic among sites deployed in multiple geographic locations. By serving content from many different points in the Internet, GSLB alleviates the impact of network bandwidth bottlenecks and provides robustness in case of network failures at a particular site. Users can be automatically directed to the nearest or least loaded site at the time of the request, minimizing the likelihood of long download delays and/or service disruptions.

You can use NetScaler appliance's global server load balancing for:

- Disaster recovery or high availability by configuring an Active-standby data center setup that consists of an active and a standby data center. When a failover occurs as a result of a disaster event, the standby data center becomes operational.
- High availability and speed by configuring an active-active data center setup that consists of multiple active data centers. Client requests are load balanced across active data centers.
- Directing client requests to the data center that is closest in geographical distance or network distance by configuring a proximity setup.
- Full-DNS resolutions, GSLB processes DNS queries of the A, AAAA and CNAME types, and the DNS function option can process DNS queries of all other types, such as MX and PTR. Also, if the recursive resolution is enabled, the appliance will forward DNS queries for domain names that are not configured on the NetScaler appliance.

For more information, see Global Server Load Balancing.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bandwidth Utilization Using Cache Redirection Functionality

The volume of web traffic on the Internet is enormous and a large percentage of that traffic is redundant. Multiple clients ask web servers for the same content repeatedly leading to inefficient use of bandwidth. To relieve the origin web server of processing each request, Internet Service Providers (ISPs) can use the cache redirection feature of NetScaler appliance and serve the content from a cache server instead of from the origin server. The NetScaler appliance analyzes incoming requests, sends requests for cacheable data to cache servers, and sends non-cacheable requests and dynamic HTTP requests to origin servers. Cache redirection feature of NetScaler is policy-based, and by default, requests that match a policy are sent to the origin server, and all other requests are sent to a cache server. You can combine content switching with cache redirection to cache selective content and serve content from specific cache servers for specific types of requested content.

For more information, see Cache Redirection.

NetScaler TCP Optimization

The NetScaler appliance provides advanced TCP tuning and optimization techniques and capabilities that are well suited to modern 3.5 and 4G networks, improving user experience and perceived download speeds significantly.

This section focuses on detailed instructions relevant to:

- Choosing and inserting an appropriate NetScaler T1000 Series model in a mobile network for TCP optimization
- Full configuration instructions related to not only TCP optimization but also for appropriate Layer-2 and Layer-3 configuration of the T1 device

The section includes the following topics:

- Getting Started
- Managment Network
- Licensing
- High Availability
- Gi-LAN Integration
- TCP Optimization Configuration

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Optimizing TCP Performance Using TCP NILE
- Analytics and Reporting
- Real-time Statistics
- SNMP
- Technical Recipes
- Troubleshooting Guidelines
- Frequently Asked Questions

Getting Started

Hardware

NetScaler provides a wide breath of NetScaler models that might be loosely based on two factors:

- Capacity, currently ranging from hundreds of Mbps for the low-end VPX appliance to 160Gbps for the high-end 25000 MPX series appliance
- Telco grade, with the availability of the T1000 series for Telco datacenters.

Your NetScaler® sales or Support representative can help you select the appropriate hardware for your demo, trial, or production needs.

The remainder of this section uses a NetScaler T1200 as a reference hardware. Note that putting aside superficial differences related to number and notation of available interfaces (see `*` in note) or well-documented limitations of NetScaler VPX (see `*` in note) the instructions should apply mostly verbatim regardless of the NetScaler model selected.

NOTE

`*` For instance a the T1010 model only has 12x1GbE typically marked as 1/1-1/12 rather than the 10/x notation used in this document.

`**` A NetScaler VPX instance typically doesn't support LACP aggregation; it might also not support VLAN tagging.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Initial Setup

Through Serial Console

After a serial cable is connected, you can log on to the NetScaler appliance with the following credentials:

- Username: nsroot
- Password: nsroot

Once logged in, configure the basic details of the NetScaler appliance as shown in the screen capture below.

Example:

```
set ns config –IPAddress <ip_addr> -netmask <netmask>

saveconfig

reboot -warm
```

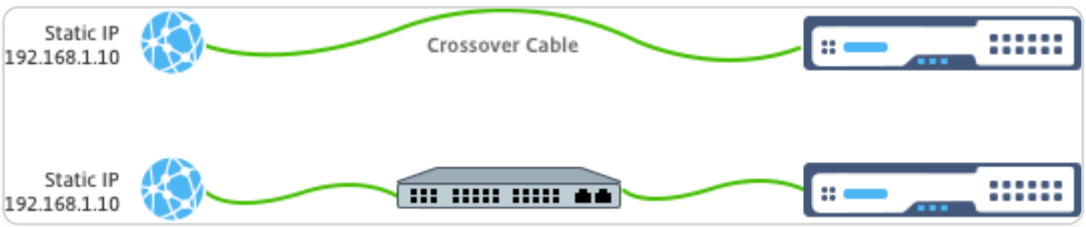
After you restart the appliance, you might use SSH for further configuration of the T1100 nodes.

Through LOM

Lights out Management (LOM) port on the front panel of the NetScaler appliance allows operator to remotely monitor and manage the appliance independently of the operating system. Operator can change the IP address, power cycle, and perform a code dump by connecting to the NetScaler appliance through the LOM port.

Default IP Address of LOM port is 192.168.1.3

Figure. Intial Configuration of LOM Module



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Set a static IP on your laptop and plug it directly into the LOM interface with a crossover cable or into a switch in the same broadcast domain as the LOM interface.

For initial configuration, type the port's default address: `<http://192.168.1.3>` in a web browser and change the LOM port's default IP address.

Refer to Configuration Guides for further details.

Software

The NetScaler TCP optimization for mobile networks is constantly evolving. The capabilities and tunings outlined in this document require a NetScaler Telco build. Here is an example showing the NetScaler Telco build.

Example:

```
show ver

NetScaler NS11.0: Build 64.957.nc, Date: Aug 26 2016, 02:00:23
```

If the T1000 has not shipped with the appropriate build revision, contact the NetScaler Customer Support.

IMPORTANT

Both the appliances should have the same software image.

SSH Client

A NetScaler appliance can be configured by using either the CLI or the HTML5 GUI. However, this section provides only CLI-based instructions.

While the CLI is accessible through the NetScaler serial console, an SSH client is normally recommended to allow for remote NetScaler configuration.

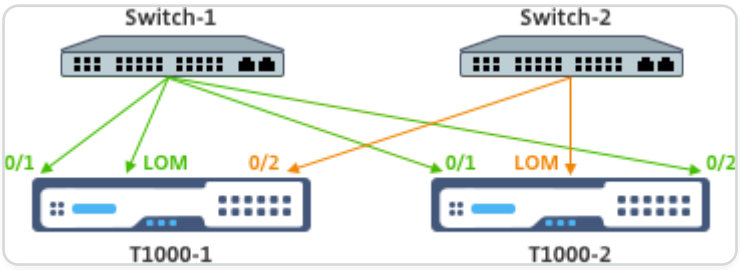
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Management Network

Connectivity

Most NetScaler devices offer redundant 1GbE OAM ports, notated as 0/1 and 0/2. To provide for redundancy in case of a switch failure, you should connect the relevant ports to different upstream switches.

A high-level overview of the recommended connectivity is outlined in the following diagram:



After the NetScaler appliance is connected to the management network, subsequent configuration steps can be performed remotely using SSH or web connectivity to the CLI and GUI respectively.

Routing

The add route command may be used to configure any routes appropriate to the management network. The relevant gateway should be reachable on the NSIP subnet, as shown below.

Example:

```
add route <network>  <netmask>  <gateway>
```

Licensing

A valid license file should be installed on the NetScaler appliance. The license should support at least as many Gbps as the expected maximum Gi-LAN throughput.

License files should be copied through an SCP client to the /nsconfig/license of the appliance, as shown in the screen capture below.

EXample:

```
shell ls /nsconfig/license/
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
CNS_V3000_SERVER_PLT_Retail.lic ssl
```

Do a warm restart to apply the new license, as shown in the screen capture below.

EXample:

```
reboot -warm

Are you sure you want to restart NetScaler (Y/N)? [N]:y

Done
```

After the restart completes, verify that the license has been properly applied, by using the show license CLI.

In the example below a 3Gbps Premium license has been successfully installed.

Example:

```
> show license

            License status:

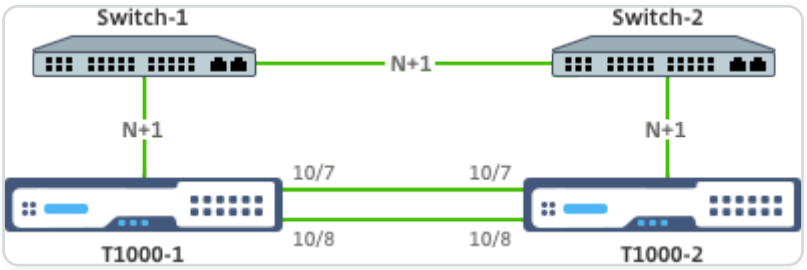
High Availability

High availability (HA) refers to an active-standby operational mode of a NetScaler device pair. Each device has its own dedicated management IP address. All other IP addresses are owned by the active device in the pair.

Connectivity

While there are multiple connectivity options for a NetScaler HA pair, the most recommended one is depicted in the following diagram:



In the above diagram, the N+1 red links between each T1000 and the respective switch imply N+1 redundancy - as explained in Connectivity. For instance, considering a 45 Gbps Gi-LAN N=5 is an appropriate value, with 6x10GbE LACP channels between each switch and the respective T1000 as well as between the two switches.

An extra pair of links is recommended between the NetScaler pair, to provide for HA communication isolation from the OAM network.

Gi-LAN Integration

Typically, a NetScaler appliance is inserted as a separate L3 inline node in the Gi-LAN, similarly to an L3 router.

Figure: A simple depiction of a Gi-LAN

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Connectivity

A physical NetScaler connectivity to upstream switches is recommended to provide for sufficient redundancy. For example, assuming that a NetScaler appliance is inserted in a Gi-LAN that is handling a total (uplink+downlink) of 24Gbps, connectivity with 4x10GbE or more interfaces is recommended. This effectively provides for N+1 redundancy in case of a link failure.

The relevant ports on the upstream switch should be configured for LACP port aggregation. The relevant configuration on NetScaler is outlined below:

Connectivity Configuration:

```
set interface 10/1 –tagall ON –lacpMode ACTIVE –lacpKey 1

set interface 10/2 –tagall ON –lacpMode ACTIVE –lacpKey 1

set interface 10/3 –tagall ON –lacpMode ACTIVE –lacpKey 1

set interface 10/4 –tagall ON –lacpMode ACTIVE –lacpKey 1
```

You can verify the appropriate functionality of LACP using the “show interface” command:

show interface:

```
sh interface LA/1

    1)      Interface LA/1 (802.3ad Link Aggregate) #39
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            flags=0x4100c020 <ENABLED, UP, AGGREGATE, UP, HAMON, 802.1q>

            MTU=1500, native vlan=1, MAC=02:e0:ed:33:88:b0, uptime
340h11m56s

            Requested: media NONE, speed AUTO, duplex NONE, fctl NONE,

            throughput 0

            Actual: throughput 4000

            LLDP Mode: NONE,

            RX: Pkts(918446) Bytes(110087414) Errs(0) Drops(795989)
Stalls(0)

            TX: Pkts(124113) Bytes(15255532) Errs(0) Drops(0) Stalls(0)

            NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0)
Muted(0)

            Bandwidth thresholds are not set.
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Disable the remaining unused interfaces and turn off the monitor.

set interface 10/5 –haMonitor OFF
```

Command:

```
set interface 10/24 –haMonitor OFF

disable interface 10/5

disable interface 10/24
```

Configuration of physical interfaces is not shared across the two NetScaler units. Hence, the above commands must be run across both NetScaler nodes in case of an HA pair deployment.

HA Configuration

All other configuration parameters are shared between the NetScaler nodes of an HA pair. Hence, HA sync should be enabled prior to any other configuration commands being run. Basic HA configuration involves the following steps:

1\. Using the exact same NetScaler hardware, software, and license: HA pairs are not supported between different models (i.e. a T1100 and an MPX21550) or same models with different firmware levels. Refer to the appropriate instructions on upgrading an existing HA pair - Upgrading to Release 11.1.

2\. Establishing the HA pair.

Example:

```
netscaler-1> add HA node 1 <netscaler-2-NSIP>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
netscaler-2> add HA node 1 <netscaler-1-NSIP>
```

3\. Verify the HA pair establishment running the following command in either node; both nodes should be visible, one of them as Primary (active), the other as a Secondary (standby).

Example:

```
show HA node
```

4\. Enable failsafe mode and maxFlips. This ensures that in case of a route monitor failure on both nodes at least one node remains active without active/standby status constantly switching.

Example:

```
set HA node –failsafe ON

set HA node -maxFlips 3 -maxFlipTime 1200
```

5\. Finally, enable HA sync to occur over the dedicated intra-NetScaler ports rather than the OAM network.

Example:

```
add vlan 4080 -aliasName syncVlan

set HA node -syncvlan 4080
```

NOTE

The VLAN 4080 in the commands in the above example shouldn’t be taken literally. Any unused VLAN-ID might be reserved.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

VLAN Configuration

After the physical interfaces have been appropriately configured, you might configure the appropriate Gi-LAN VLANs. For instance, consider a rather simple Gi-LAN environment with an ingress/egress VLAN pair with 100/101 VLAN-identifier respectively.

The following commands configure the relevant VLANs on top of the LACP channel created in the prior step.

```
add vlan 100

add vlan 101

bind vlan 100 –ifnum LA/1 –tagged

bind vlan 101 –ifnum LA/1 –tagged
```

IPv4 Configuration

Typically, a NetScaler appliance requires one SNIP per VLAN. The example below assumes that the networks outlined in the Gi-LAN integration diagram, given in the begining of this page, have a /24 subnet mask:

```
add ns ip 192.168.1.254 255.255.255.0 –vserver DISABLED –mgmtAccess
DISABLED

add ns ip 192.168.2.254 255.255.255.0 –vserver DISABLED –mgmtAccess
DISABLED
```

After the SNIPs have been configured they should be associated with the appropriate VLAN:

```
bind vlan 100 –IPAddress 192.168.1.254 255.255.255.0

bind vlan 101 –IPAddress 192.168.2.254 255.255.255.0
```

IPv4 Static Routing

The example outlined in the Management Network section calls for only a couple of static routing rules:

- A 10.0.0.0/8 static route to the clients through the ingress router

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- A default route to the internet through the egress router

Example:

```
add route 0.0.0.0 0.0.0.0 192.168.2.1

add route 10.0.0.0 255.0.0.0 192.168.1.1
```

IPv4 Policy-Based (VLAN - VLAN) routing

A NetScaler appliance allows for policy-based routing instead of static routing, with routing decisions usually keyed against the incoming interface and/or VLAN rather than destination IP. Policy-based routing is either a convenient alternative, in case the client source IP address range is subject to periodic changes, or a mandatory consideration, in case a packet's destination IP address is not sufficient by itself to reach a routing decision (i.e. in case of overlapping client IP addresses across multiple VLANs).

Example:

```
add ns pbr fromWirelessToInternet ALLOW –nextHop 192.168.2.1 –vlan 100 –
priority 10

Done

 add ns pbr fromInternetToWireless ALLOW –nextHop 192.168.1.1 –vlan 200 –
priority 20

Done

apply ns pbrs
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IPv6 Configuration

The following commands assign IPv6 SNIP per vlan. The example below assumes that the networks outlined in the Figure: A simple depiction of a Gi-LAN in this page have a /64 subnet mask:

Command:

```
add ns ip6 fd00:192:168:1::254/64 -vServer DISABLED –mgmtAccess DISABLED

add ns ip6 fd00:192:168:2::254/64 -vServer DISABLED –mgmtAccess DISABLED

bind vlan 100 -IPAddress fd00:192:168:1::254/64

bind vlan 200 -IPAddress fd00:192:168:2::254/64
```

IPv6 Routing

After IPv6 addressing is complete, IPv6 static routing might be configured:

- A fd00:10::/64 static route to the clients via the ingress router
- A default route to the internet via the egress router

Example:

```
add route6 fd00:10::/64 fd00:192:168:1::1

add route6 ::/0 fd00:192:168:2::1
```

Or using policy-based routing:

Example:

```
add ns pbr6 fromWirelessToInternetv6 ALLOW -vlan 100 -priority 10 -nextHop
fd00:192:168:2::1

add ns pbr6 fromInternetToWirelessv6 ALLOW -vlan 200 -priority 20 -nextHop
fd00:192:168:1::1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
apply ns pbr6
```

LACP Redundancy and Failover

In case of an HA configuration, it's recommended to leverage the throughput option to configure a low threshold for the LACP channel. For instance, consider a 25Gbps Gi-LAN and a 4x10GbE channel between each NetScaler appliance in the HA pair and the upstream switch to provide N+1 link redundancy:

Example:

```
set interface LA/1 –haMonitor ON –throughput 29000
```

In case of a double-link failure between the primary appliance and the upstream switch the maximum Gi-LAN throughput that can be supported would fall to 20Gbps. A 29Gbps low threshold per the example above would result in a redundancy switchover event to the secondary appliance (which has not suffered similar link failures) so that Gi-LAN traffic is not affected.

Route Monitors

In addition to LACP redundancy, route monitor checks might be configured and associated with the HA pair configuration. Route monitor checks can be useful to detect failures between the NetScaler appliance and the next-hop routers, especially if said routers are not directly connected but through an upstream switch.

A typical HA route monitor configuration per the sample Gi-LAN in section 2.5.1 is outlined below:

```
add route 192.168.1.0 255.255.255.0 192.168.1.1 -msr ENABLED -monitor arp

add route 192.168.2.0 255.255.255.0 192.168.2.1 -msr ENABLED -monitor arp

bind HA node -routeMonitor 192.168.1.0 255.255.255.0

bind HA node -routeMonitor 192.168.2.0 255.255.255.0
```

TCP optimization configuration

Before configuring TCP optimization, apply the following basic configuration settings on the NetScaler appliance:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Initial configuration:

```
enable ns feature LB IPv6PT

enable ns mode FR L3 USIP MBF Edge USNIP PMTUD

disable ns feature SP

disable ns mode TCPB

set lb parameter -preferDirectRoute NO

set lb parameter -vServerSpecificMac ENABLED

set l4param -l2ConnMethod Vlan

set rsskeytype -rsstype SYMMETRIC

set ns param -useproxyport DISABLED
```

NOTE

Restart the NetScaler appliance if you change the rsskeytype system parameter.

TCP termination

For NetScaler T1 to apply TCP optimization it needs to first terminate incoming TCP traffic. Towards this end, a wildcard TCP vserver should be created and configured to intercept ingress traffic and then forward it to the Internet router.

Static or dynamic routing environment

For environments with static or dynamic routing in place, vserver can rely on routing table info to forward packets towards internet router. Default route must point to the internet router and also routing entries for client subnets towards wireless router should be in place:

Example:

```
add lb vserver vsrv-wireless TCP * * -persistenceType NONE -Listenpolicy
"CLIENT.VLAN.ID.EQ(100) && SYS.VSERVER(\"vsrv-wireless\").STATE.EQ(UP)" -m
IP -cltTimeout 9000
```

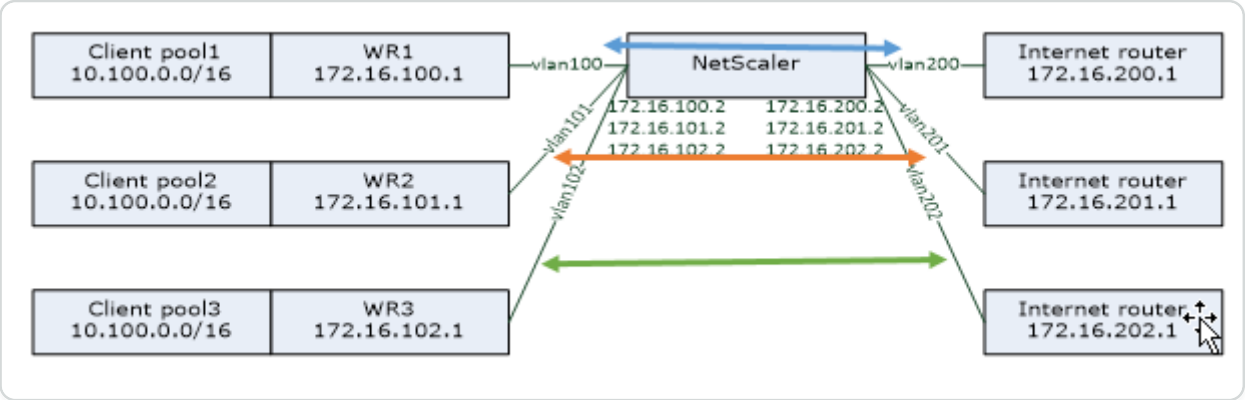
© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add route 0.0.0.0 0.0.0.0 192.168.2.1

add route 10.0.0.0 255.0.0.0 192.168.1.1
```

VLAN-to-VLAN (PBR) environment

There are customer environments where subscriber traffic is segmented to multiple flows and needs to be forwarded to different routers based on incoming traffic parameters. Policy Based Routing (PBR) can be used to route packets based on incoming packet parameters, such as VLAN, MAC address, Interface, source IP, source port, destination IP address, and destination port.



Example:

```
add lb vserver vsrv-wireless TCP * * -m IP -l2Conn ON -listenpolicy
"CLIENT.VLAN.ID.EQ(100) || CLIENT.VLAN.ID.EQ(101) ||
CLIENT.VLAN.ID.EQ(102)"

add ns pbr pbr-vlan100-to-vlan200 ALLOW -vlan 100 -nexthop 172.16.200.1

add ns pbr pbr-vlan101-to-vlan201 ALLOW -vlan 101 -nexthop 172.16.201.1

add ns pbr pbr-vlan102-to-vlan202 ALLOW -vlan 102 -nexthop 172.16.202.1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Using Policy Based Routing to route TCP optimized traffic is a new feature added in release 11.1 50.10. For previous releases, having multiple “mode MAC” vserver entities per VLAN is an alternative solution for multi-VLAN environments. Each vserver has a bound service representing the internet router for the particular flow.

Example:

```
add server internet_router_1 172.16.200.1

add server internet_router_2 172.16.201.1

add server internet_router_3 172.16.202.1

add service svc-internet-1 internet_router_1 TCP * -usip YES -useproxyport
NO

add service svc-internet-2 internet_router_2 TCP * -usip YES -useproxyport
NO

add service svc-internet-3 internet_router_3 TCP * -usip YES -useproxyport
NO

bind service svc-internet-1 -monitorName arp

bind service svc-internet-2 -monitorName arp

bind service svc-internet-3 -monitorName arp
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lb vserver vsrv-wireless-1 TCP * * -Listenpolicy
"CLIENT.VLAN.ID.EQ(100) && SYS.VSERVER(\"vsrv-wireless-1\").STATE.EQ(UP)"
-m MAC -l2Conn ON

add lb vserver vsrv-wireless-2 TCP * * -Listenpolicy
"CLIENT.VLAN.ID.EQ(101) && SYS.VSERVER(\"vsrv-wireless-2\").STATE.EQ(UP)"
-m MAC -l2Conn ON

add lb vserver vsrv-wireless-3 TCP * * -Listenpolicy
"CLIENT.VLAN.ID.EQ(102) && SYS.VSERVER(\"vsrv-wireless-3\").STATE.EQ(UP)"
-m MAC -l2Conn ON

bind lb vserver vsrv-wireless-1 svc-internet-1

bind lb vserver vsrv-wireless-2 svc-internet-2

bind lb vserver vsrv-wireless-3 svc-internet-3
```

NOTE:

The vserver mode is MAC in contrast to previous examples where it is mode IP. This is required to retain the destination IP information when we have service(s) bound to vserver. Also, the additional PBR configuration need to route non-optimized traffic.

TCP optimization

Out-of-the-box NetScaler TCP termination is configured for TCP pass-through functionality. TCP pass-through essentially means that NetScaler T1 may transparently intercept a client-server TCP

© 1997–2026 Citrix Systems, Inc. All rights reserved.

stream but does not retain separate client/server buffers or otherwise apply any optimization techniques.

To enable TCP optimization a TCP profile, named as nstcpprofile, is used to specify TCP configurations that is used if no TCP configurations are provided at the service or virtual server level and it should be modified as follows:

Command:

```
add ns tcpProfile nstcpprofile -WS ENABLED -SACK ENABLED -WSVal 8 -mss
1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -bufferSize
4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA ENABLED
-sendBuffsize 4000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED
-ecn ENABLED -frto ENABLED -maxcwnd 1000000 -fack ENABLED -rstMaxAck
enABLED -tcpmode ENDPOINT
```

NOTE:

If there is not any profile explicitly created and bound to vserver and service, the profile nstcp_default_profile is bound by default.

In case of multiple TCP profiles requirement, extra TCP profiles can be created and associated with the appropriate virtual server

Command:

```
add ns tcpProfile custom_profile -WS ENABLED -SACK ENABLED -WSVal 8 -mss
1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800 -bufferSize
4000000 -flavor BIC -dynamicReceiveBuffering ENABLED -KA ENABLED
-sendBuffsize 4000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED
-ecn ENABLED -frto ENABLED -maxcwnd 1000000 -fack ENABLED -rstMaxAck
enABLED -tcpmode ENDPOINT

set lb vserver vsrv-wireless -tcpProfileName custom_profile
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

For deployments with vserver -m MAC and service, same profile should be associated with service.

```
set service svc-internet -tcpProfileName custom_profile
```

TCP optimization capabilities

Most of the relevant TCP optimization capabilities of a NetScaler appliance are exposed through a corresponding TCP profile. Typical CLI parameters that should be considered when creating a TCP profile are the following:

1. **Window Scaling (WS)**: TCP Window scaling allows increasing the TCP receive window size beyond 65535 bytes. It helps improving TCP performance overall and specially in high bandwidth and long delay networks. It helps with reducing latency and improving response time over TCP.
2. **Selective acknowledgment (SACK)**: TCP SACK addresses the problem of multiple packet loss which reduces the overall throughput capacity. With selective acknowledgement the receiver can inform the sender about all the segments which are received successfully, enabling sender to only retransmit the segments which were lost. This technique helps T1 improve overall throughput and reduce the connection latency.
3. **Window Scaling Factor (WSVal)**: Factor used to calculate the new window size. It must be configured with a high value in order to allow the advertised window by NS to be at least equal to the buffer size.
4. **Maximum Segment Size (MSS)**: MSS of a single TCP segment. This value depends on the MTU setting on intermediate routers and end clients. A value of 1460 corresponds to an MTU of 1500.
5. **maxBurst**: Maximum number of TCP segments allowed in a burst.
6. **Initial Congestion Window size(initialCwnd)**: TCP initial congestion window size determines the number of bytes which can be outstanding in beginning of the transaction. It enables T1 to send those many bytes without bothering for congestion on the wire.
7. **Maximum OOO packet queue size(oooQSize)**: TCP maintains Out Of Order queue to keep the OOO packets in the TCP communication. This setting impacts system memory if the queue size is long as the packets need to be kept in runtime memory. Thus this needs to be kept at optimized level based on the kind of network and application characteristics.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

8. **Minimum RTO(minRTO)**: The TCP retransmission timeout is calculated on each received ACK based on internal implementation logic. The default retransmission timeout happens at 1 second to start with and this can be tweaked with this setting. For second retransmission of these packets RTO will be calculated by N*2 and then N*4 … N*8… goes on till last retransmission attempt.
9. **bufferSize/sendBuffsize**: these refer to the maximum amount of data that the T1 may receive from the server and buffer internally without sending to the client. They should be set to a value larger (at least double) than the Bandwidth Delay Product of the underlying transmission channel.
10. **flavor**: this refers to the TCP congestion control algorithm. Valid values are Default, BIC, CUBIC, Westwood and Nile.
11. **Dynamic receive buffering**: allows the receive buffer to be adjusted dynamically based on memory and network conditions. It will fill up the buffer as much as it's required to keep the client's download pipe full instead of filling up, by reading ahead from server, a fixed size buffer, as latter is specified in TCP profile and typically based on criteria such as 2*BDP, for a connection. NetScaler T1 monitors the network conditions to the client and estimates how much it should read ahead from the server.
12. **Keep-Alive (KA)**: Send periodic TCP keep-alive (KA) probes to check if peer is still up.
13. rstWindowAttenuate: Defending TCP against spoofing attacks. It will reply with corrective ACK when a sequence number is invalid.
14. **rstMaxAck**: Enable or disable acceptance of RST that is out of window yet echoes highest ACK sequence number.
15. **spoofSynDrop**: Drop of invalid SYN packets to protect against spoofing.
16. **Explicit Congestion Notification(ecn)**: It sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption.
17. **Forward RTO-Recovery**: In case of spurious retransmissions, the congestion control configurations are reverted to their original state.
18. **TCP maximum congestion window (maxcwnd)**: TCP maximum congestion window size that is user configurable.
19. **Forward acknowledgment (FACK)**: To avoid TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either T1 or a client) control the amount of data injected into the network during retransmission timeouts.
20. **tcpmode**: TCP optimization modes for specific profile. There are two TCP optimization modes - Transparent and Endpoint.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Endpoint. In this mode, the appliance manages the client and server connections seperately.
- Transparent. In the transparent mode the clients need to access the servers directly, with no intervening virtual server. The server IP addresses must be public because the clients need to be able to access them.

Silently dropping idle connections

In a telco network, almost 50 percent of a NetScaler appliance's TCP connections become idle, and the appliance sends RST packets to close them. The packets sent over radio channels activate those channels unnecessarily, causing a flood of messages that in turn cause the appliance to generate a flood of service-reject messages. The default TCP profile now includes DropHalfClosedConnOnTimeout and DropEstConnOnTimeout parameters, which by default are disabled. If you enable both of them, neither a half closed connection nor an established connection causes a RST packet to be sent to the client when the connection times out. The appliance just drops the connection.

```
set ns tcpProfile nstcpprofile  -DropHalfClosedConnOnTimeout ENABLED

set ns tcpProfile nstcpprofile  -DropEstConnOnTimeout ENABLED
```

Analytics and Reporting

The TCP Speed Reporting is a NetScaler feature which extracts TCP connection statistics, as a measure of TCP download and upload performance, and is utilized in TCP Insight reports of the NetScaler Application Delivery Management (ADM). To achieve this, NetScaler monitors each TCP connection, locates packet bursts on an idle time-out basis and reports key metrics (such as byte count, retransmitted byte count and duration) for the identified maximum burst. TCP Speed Reporting feature is enabled by default, support both TCP and HTTP vServers and depends on the Appflow/ULFD reporting infrastructure.

Real-time Statistics

The stat command might be used to verify that TCP optimization is properly applied:

Command:

```
> stat lb vserver vsrv-wireless

Virtual Server Summary
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```

```

The Total counters should constantly increase for an operational system. In addition, the Rate counters should be non-zero.

NOTE

The preceding output is from an operational yet idle lab system, explaining the zero rate.

SNMP

SNMP agent can be queried for system specific information from a remote device (SNMP Manager). Based on the query, the agent searches for the equal object identifier (OID) in the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

management information base (MIB) for the data requested and sends the information to the SNMP Manager. The following are the most useful SNMP OIDs for Telco deployments:

Memory

- **resMemUsage (1.3.6.1.4.1.5951.4.1.1.41.2)**

Percentage of memory utilization on NetScaler.

Packet Engine CPU

- **resCpuUsage (1.3.6.1.4.1.5951.4.1.1.41.1)**

CPU utilization percentage.

- **nsCPUTable (1.3.6.1.4.1.5951.4.1.1.41.6)**

This table contains information about each CPU in NetScaler.

Indexed on: nsCPUname

- **nsCPUname (1.3.6.1.4.1.5951.4.1.1.41.6.1.1)**

The name of the CPU.

- **nsCPUusage (1.3.6.1.4.1.5951.4.1.1.41.6.1.2)**

CPU utilization percentage.

Throughput

- **allNicTotRxMbits (1.3.6.1.4.1.5951.4.1.1.71.1)**

Number of megabits received by the NetScaler appliance.

- **allNicTotTxMbits (1.3.6.1.4.1.5951.4.1.1.71.2)**

Number of megabits transmitted by the NetScaler appliance.

- **ipTotRxPkts (1.3.6.1.4.1.5951.4.1.1.43.25)**

IP packets received.

- **ipTotRxMbits (1.3.6.1.4.1.5951.4.1.1.43.27)**

Megabits of IP data received.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **ipTotTxPkts (1.3.6.1.4.1.5951.4.1.1.43.28)**

IP packets transmitted.

- **ipTotTxMbits (1.3.6.1.4.1.5951.4.1.1.43.30)**

Megabits of IP data transmitted.

Connections

Active connections:

- **tcpActiveServerConn (1.3.6.1.4.1.5951.4.1.1.46.8)**

Connections to a server currently responding to requests.

Total connections:

- **tcpCurServerConn (1.3.6.1.4.1.5951.4.1.1.46.1)**

Server connections, including connections in the Opening, Established, and Closing state.

- **tcpCurClientConn (1.3.6.1.4.1.5951.4.1.1.46.2)**

Client connections, including connections in the Opening, Established, and Closing state.

Note: Because of SYN-Cookie, this doesn't include Client in Opening state

- **tcpTotZombieCltConnFlushed (1.3.6.1.4.1.5951.4.1.1.46.26)**

Client connections that are flushed because the client has been idle for some time.

- **tcpTotZombieSvrConnFlushed (1.3.6.1.4.1.5951.4.1.1.46.27)**

Server connections that are flushed because there have been no client requests in the queue for some time.

Errors

- **tcpErrSynGiveUp (1.3.6.1.4.1.5951.4.1.1.46.37)**

Attempts to establish a connection on the NetScaler that timed out.

- **tcpErrRetransmitGiveUp (1.3.6.1.4.1.5951.4.1.1.46.60)**

Number of times NetScaler terminates a connection after retransmitting the packet seven times on that connection. Retransmission happens when recieving end doesn't acknowledges the packet.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **ifInDiscards (1.3.6.1.2.1.2.2.1.13)**

The number of inbound packets which were chosen to be discarded even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space.

- **ifOutDiscards (1.3.6.1.2.1.2.2.1.19)**

The number of outbound packets which were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space.

- **ifErrTxOverflow (1.3.6.1.4.1.5951.4.1.1.54.1.36)**

Number of packets that have passed through the overflow queues, during transmission on the specified interface, since the NetScaler appliance was started or the interface statistics were cleared. This gets incremented only on congested ports.

Optimized/Bypass connections

- **tcpOptimizationEnabled (1.3.6.1.4.1.5951.4.1.1.46.131)**

Total number of connections enabled with TCP optimization.

- **tcpOptimizationBypassed (1.3.6.1.4.1.5951.4.1.1.46.132)**

Total number of connections bypassed TCP Optimization.

Technical Recipes

The NetScaler T1 models provide advanced features and a powerful policy configuration language that allow for evaluation of complex decision in runtime.

While it is not possible to evaluate all capabilities that are potentially unlocked by the T1000 features and policy configuration guide, technical receipes consider implementation of various requirements brought in by Telco operators. Feel free to re-use the “recipes” as is or adapt to your environment.

Per-user Connection Limit

The NetScaler T1 model can be configured to limit the number of connections per unique subscriber IP. With the below configuration, N concurrent TCP connections per IP (CLIENT.IP.SRC)

© 1997–2026 Citrix Systems, Inc. All rights reserved.

is allowed. For every attempt for connection beyond the configured threshold, T1 sends an RST. For maximum 2 concurrent connections per user:

Command:

```
add stream selector streamSel_usrlimit CLIENT.IP.SRC

add ns limitIdentifier limitId_usrlimit -threshold 2 -mode CONNECTION
-selectorName streamSel_usrlimit

add responder policy respPol_usrlimit
"SYS.CHECK_LIMIT(\"limitId_usrlimit\")" RESET

bind lb vserver vsrv-wireless -policyName respPol_usrlimit -priority 1
-gotoPriorityExpression END
```

Smooth Insertion/Deletion of Vserver

Many operators concern about TCP connections disruption when the NetScaler T1 model is activated inline for TCP optimization or when it is disabled for maintenance purposes. To avoid breaking existing connections when vserver is introduced, the following configuration needs to be applied before configuring or activating vserver for TCP optimization:

Command:

```
add ns acl acl-ingress ALLOW –vlan 100

add forwardingSession fwd-ingress –aclname acl-ingress

apply ns acls
```

Forwarding sessions are effective on top of routing (either static or dynamic or PBR) and create session entries for traffic that is routed (L3 mode). Any existing connection is handled by forwarding session due to corresponding sessions, and upon vserver introduction it starts capturing only new TCP connections.

ACLs can be configured to capture only specific ports like vserver, in order to avoid creating sessions for unnecessary traffic, which is memory consuming. Another option is to remove specific configuration after vserver activation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For maintenance purposes, vserver should be disabled and its state appears as OUT OF SERVICE. When this happens, the vserver terminates all connections immediately by default. To make vserver to still serve the existing connections and not accept new, the following configuration should be applied:

Command:

```
set lb vserver vsrv-wireless –downStateFlush DISABLED
```

New connections go through the routing table, and corresponding session entries are created due to forwarding sessions.

Policy-Based TCP Profiling

Policy-based TCP Profile selection allows operators to configure TCP profile dynamically for clients coming from different traffic domains (i.e. 3G or 4G). Some of the QoS metrics are different for these traffic domains, and in order to achieve better performance, you need to change some of the TCP parameter dynamically. Consider a case where clients coming from 3G and 4G hit same vserver and use same TCP profile, which have negative impact on some client's performance. AppQoE functionality can classify these clients and dynamically change TCP profile on vserver.

Example:

```
enable feature AppQoE

add ns tcpProfile nstcpprofile1 -WS ENABLED -SACK ENABLED -WSVal 8 -mss
1460 -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 800
-slowStartIncr 1 -bufferSize 4000000 -flavor BIC -KA ENABLED -sendBuffsize
4000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -frto ENABLED
-maxcwnd 1000000 -fack ENABLED -tcpmode ENDPOINT

add ns tcpProfile nstcpprofile2 -WS ENABLED -SACK ENABLED -WSVal 8 -mss
1460 -maxBurst 15 -initialCwnd 16 -oooQSize 15000 -minRTO 800
-slowStartIncr 1 -bufferSize 128000 -flavor BIC -KA ENABLED -sendBuffsize
6000000 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -frto ENABLED
-maxcwnd 64000 -fack ENABLED -tcpmode ENDPOINT
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add appqoe action action_1 -priority HIGH -tcpprofile nstcpprofile1

add appqoe action action_2 -priority HIGH -tcpprofile nstcpprofile2

add appqoe policy appqoe_4G -rule "CLIENT.VLAN.ID.EQ(100)" -action
action_1

add appqoe policy appqoe_3G -rule "CLIENT.VLAN.ID.EQ(200)" -action
action_2

bind lb vserver vsrv-wireless -policyName appqoe_4G -priority 100

bind lb vserver vsrv-wireless -policyName appqoe_3G -priority 110
```

The NetScaler T1 model is capable to receive the subscriber information dynamically through Gx or Radius or Radius and Gx interface and apply different TCP profile on a per-subscriber basis.

Command:

```
add appqoe action action_1 -priority HIGH -tcpprofile nstcpprofile1

add appqoe action action_2 -priority HIGH -tcpprofile nstcpprofile2

add appqoe policy appqoe_4G -rule "SUBSCRIBER.RULE_ACTIVE(\"3G\")" -action
action_1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add appqoe policy appqoe_3G -rule "SUBSCRIBER.RULE_ACTIVE(\"4G\")" -action
action_2
```

For integration of the NetScaler T1 model with operator control-plane network, see Telco Subscriber Management.

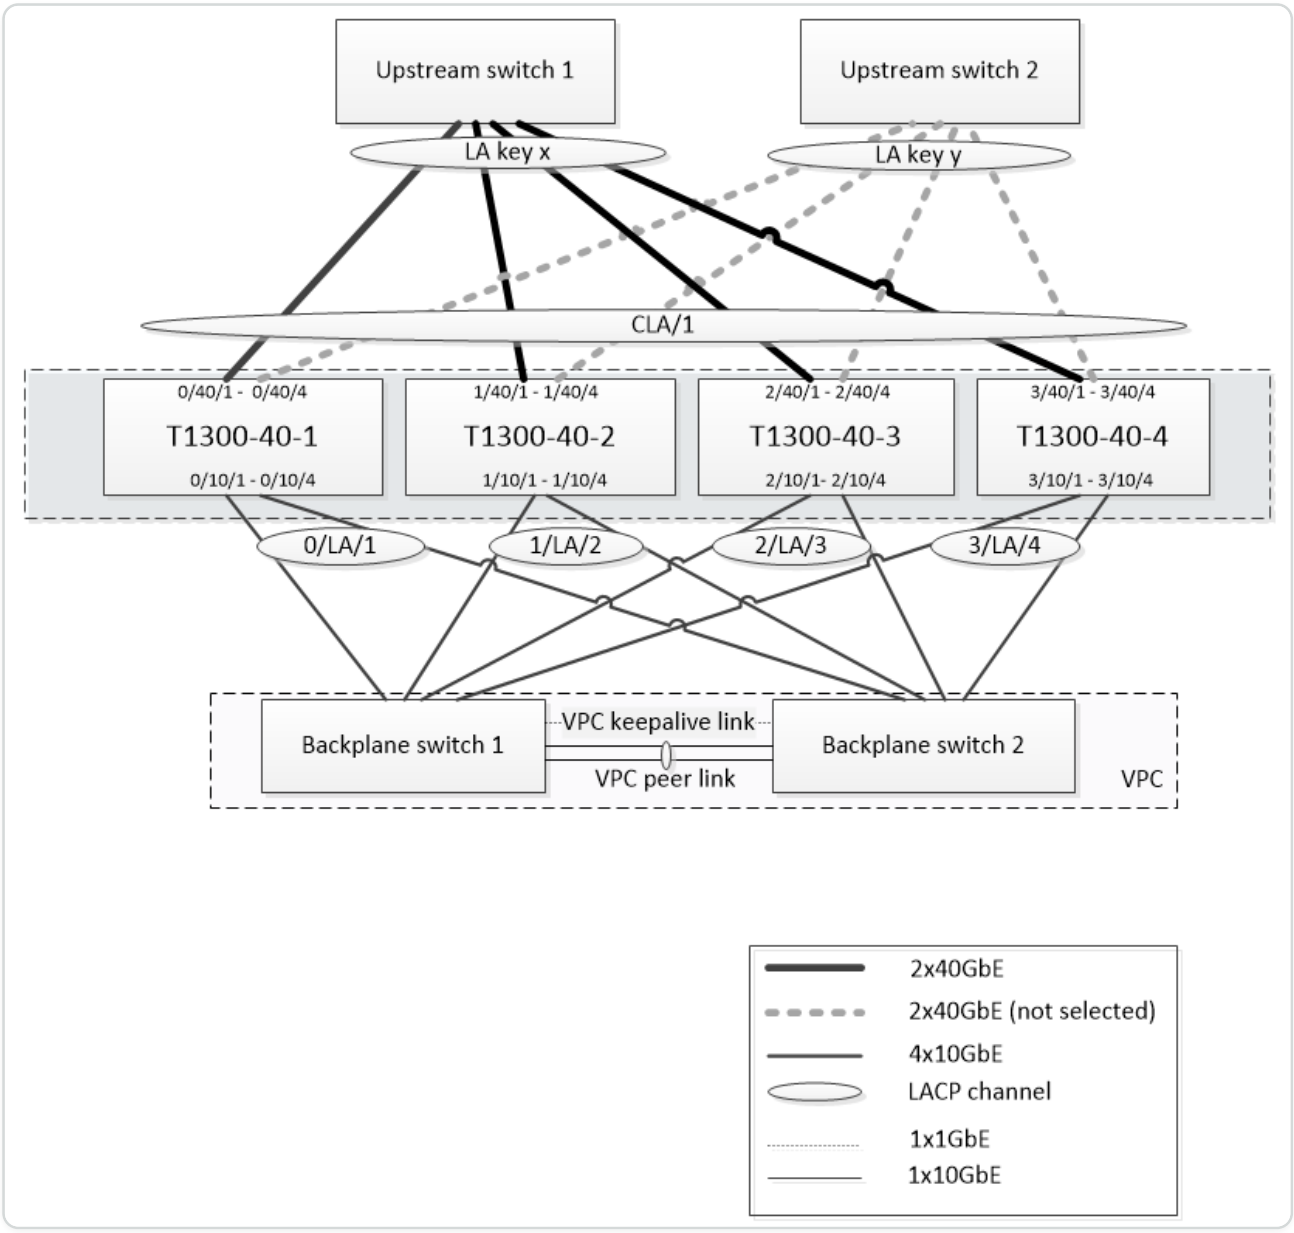
Scalability

Because TCP optimization is resource intensive, a single NetScaler appliance, even a high end – appliance, might not be able to sustain high Gi-LAN throughputs. To expand the capacity of your network, you can deploy NetScaler appliances in an N+1 cluster formation. In a cluster deployment, the NetScaler appliances work together as a single system image. The client traffic is distributed across the cluster nodes with the help of external switch device.

Topology

Figure 1 is an example of a cluster consisting of four T1300-40G nodes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The setup shown in Figure 1 has the following properties:

1. All cluster nodes belong to the same network (also known as an L2 cluster).
2. Data plane and backplane traffic are handled by different switches.
3. Assuming Gi-LAN throughput is 200 Gbps and that a T1300-40G appliance can sustain 80Gbps of throughput, we need three T1300-40G appliances. To provide redundancy in case of single cluster node failure, we deploy four appliances in total.
4. Each node will receive up to 67Gbps of traffic (50Gbps in normal operating conditions and 67Gbps in case of single cluster node failure), so it needs 2x40Gbps connections to the upstream switch. To provide redundancy in case of switch failure, we deploy a couple of upstream switches and double the number of connections.
5. Cluster Link Aggregation (CLAG) is used to distribute traffic across cluster nodes. A single CLAG handles both client and server traffic. Link Redundancy is enabled on the CLAG, so only

© 1997–2026 Citrix Systems, Inc. All rights reserved.

one "subchannel" is selected at any given time and handles the traffic. If some link fails or throughput falls below specified threshold, the other subchannel is selected.

6. The upstream switch performs symmetric port-channel load balancing (for example, source-dest-ip-only algorithm of Cisco IOS 7.0(8) N1(1)) so that forward and reverse traffic flows are handled by the same cluster node. This property is desirable because it eliminates packet reordering, which would degrade TCP performance.
7. Fifty percent of data traffic is expected to be steered to backplane, which means each node will steer up to 34Gbps to other cluster nodes (25Gbps in normal operating conditions and 34Gbps in case of single cluster node failure). Thus, each node needs at least 4x10G connections to the backplane switch. To provide redundancy in case of switch failure, we deploy a couple of backplane switches and double the number of connections. Link redundancy is not currently supported for backplane, so Cisco VPC or equivalent technology is desired to achieve switch-level redundancy.
8. MTU size of steered packets is 1578 bytes, so backplane switches must support an MTU more than 1500 bytes.

Note: The design depicted in Figure 1 is also applicable to T1120 and T1310 appliances. For T1310 we would use 40GbE interfaces for the backplane connections, since it lacks 10GbE ports.

Note: While this document uses Cisco VPC as an example, if working with non-Cisco switches alternate equivalent solutions could be used, such as Juniper’s MLAG.

Note: While other topologies such as ECMP instead of CLAG are possible, they are not currently supported for this particular use case.

Configuring TCP Optimization in a NetScaler T1000 Cluster

After physical installation, physical connectivity, software installation, and licensing are completed, you can proceed with the actual cluster configuration. The configurations described below apply to the cluster depicted in Figure 1.

Note: For more information about cluster configuration, see Setting up a NetScaler cluster.

Assume that the four T1300 nodes in Figure 1 have the following NSIP addresses:

Four T1300 nodes with NSIP address:

```
T1300-40-1: 10.102.29.60

T1300-40-2: 10.102.29.70
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
T1300-40-3: 10.102.29.80

T1300-40-4: 10.102.29.90
```

The cluster will be managed through the cluster IP (CLIP) address, which is assumed to be 10.78.16.61.

Setting Up the Cluster

To begin configuring the cluster shown in Figure 1, log on to the first appliance that you want to add to the cluster (for example, T1300-40-1) and do the following.

1. At the command prompt, enter the following commands:

   Command:

   ```
   > add cluster instance 1

   > add cluster node 0 10.102.29.60 -state ACTIVE

   > add ns ip 10.102.29.61 255.255.255.255 -type clip

   > enable cluster instance 1

   > save ns config

   > reboot –warm
   ```

2. After the appliance restarts, connect to the Cluster IP (CLIP) address and add the rest of the nodes to the cluster:

   Command:

   ```
   > add cluster node 1 10.102.29.70 -state ACTIVE

   > add cluster node 2 10.102.29.80 -state ACTIVE

   > add cluster node 3 10.102.29.90 –state ACTIVE

   > save ns config
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Connect to the NSIP address of each of the newly added nodes and join the cluster:

   Command:

   ```
   > join cluster -clip 10.102.29.61 -password nsroot

   > save ns config

   > reboot –warm
   ```

4. After the nodes restart, proceed with backplane configuration. On the cluster IP address, enter the following commands to create an LACP channel for the backplane link of each cluster node:

   Command:

   ```
   > set interface 0/10/[1-8] –lacpkey 1 –lacpmode ACTIVE

   > set interface 1/10/[1-8] –lacpkey 2 –lacpmode ACTIVE

   > set interface 2/10/[1-8] –lacpkey 3 –lacpmode ACTIVE

   > set interface 3/10/[1-8] –lacpkey 4 –lacpmode ACTIVE
   ```

5. Similarly, configure dynamic LA and VPC on the backplane switches. Make sure the MTU of the backplane switch interfaces is at least 1578 bytes.
6. Verify the channels are operational:

   Command:

   ```
   > show channel 0/LA/1

   > show channel 1/LA/2

   > show channel 2/LA/3

   > show channel 3/LA/4
   ```

7. Configure the cluster node backplane interfaces.

   Command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> set cluster node 0 -backplane 0/LA/1

> set cluster node 1 -backplane 1/LA/2

> set cluster node 2 -backplane 2/LA/3

> set cluster node 3 –backplane 3/LA/4
```

8. Check the cluster status and verify that the cluster is operational:

```
> show cluster instance

> show cluster node
```

For more information on cluster setup, see Setting up a NetScaler cluster

Distributing Traffic Across Cluster Nodes

After you have formed theNetScaler cluster, deploy Cluster Link Aggregation (CLAG) to distribute traffic across cluster nodes. A single CLAG link will handle both client and server traffic.

On the cluster IP address, execute the following commands to create the Cluster Link Aggregation (CLAG) group shown in Figure 1:

Command:

```
> set interface 0/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster

> set interface 1/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster

> set interface 2/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster

> set interface 3/40/[1-4] -lacpMode active -lacpKey 5 -lagType Cluster
```

Configure dynamic link aggregation on the external switches.

Then, enable Link Redundancy as follows:

Code:

```
> set channel CLA/1 -linkRedundancy ON -lrMinThroughput 240000
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Finally, check the channel status by entering:

Command:

```
> show channel CLA/1
```

The channel should be UP and the actual throughput should be 320000.

For more information about cluster link aggregation, see the following topics:

- Dynamic Cluster Link Aggregation
- Link Redundancy in a Cluster with LACP.

Because we will be using MAC-based forwarding (MBF), configure a linkset and bind it to the CLAG group as follows:

Command:

```
> add linkset LS/1

> bind linkset LS/1 -ifnum CLA/1
```

More information about linksets, see the following topics:

- Configuring Linksets
- Using Cluster LA Channel with Linksets

Configuring VLAN and IP Addresses

We will be using striped IP configuration, which means that IP addresses are active on all nodes (default setting). See Striped, Partially Striped, and Spotted Configurations for more information about this topic.

1. Add the ingress and egress SNIPs:

   Command:

   ```
   > add ns ip 172.16.30.254 255.255.255.0 –type SNIP

   > add ns ip 172.16.31.254 255.255.255.0 –type SNIP

   > add ns ip6 fd00:172:16:30::254/112 –type SNIP
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> add ns ip6 fd00:172:16:31::254/112 –type SNIP
```

2. Add the corresponding ingress and egress VLANs:

   Command:

```
> add vlan 30 -aliasName wireless

> add vlan 31 -aliasName internet
```

3. Bind VLANs with IPs and linkset:

   Command:

```
> bind vlan 31 -ifnum LS/1 -tagged

> bind vlan 30 -ifnum LS/1 -tagged

> bind vlan 30 -IPAddress 172.16.30.254 255.255.255.0

> bind vlan 31 -IPAddress 172.16.31.254 255.255.255.0

> bind vlan 30 -IPAddress fd00:172:16:30::254/112

> bind vlan 31 -IPAddress fd00:172:16:31::254/112
```

More ingress and egress VLANs can be added if needed.

Configuring TCP Optimization

At this point, we have applied all cluster specific commands. To complete the configuration, follow the steps described in TCP optimization configuration.

Configuring Dynamic Routing

A NetScaler cluster can be integrated into the dynamic routing environment of the customer's network. Following is an example of dynamic routing configuration using BGP routing protocol (OSPF is also supported).

1. From the CLIP address, enable BGP and dynamic routing on ingress and egress IP addresses:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Command:

```
> enable ns feature bgp

> set ns ip 172.16.30.254 –dynamicRouting ENABLED

> set ns ip 172.16.31.254 –dynamicRouting ENABLED
```

2. Open vtysh and configure BGP for the egress side:

   Code:

```
> shell

root@ns# vtysh

ns# configure terminal

ns(config)# router bgp 65531

ns(config-router)# network 10.0.0.0/24

ns(config-router)# neighbor 172.16.31.100 remote-as 65530

ns(config-router)# neighbor 172.16.31.100 update-source 172.16.31.254

ns(config-router)# exit

ns(config)# ns route-install propagate

ns(config)# ns route-install default

ns(config)# ns route-install bgp

ns(config)# exit
```

3. Configure the egress-side BGP peer to advertise the default route to the NetScaler cluster. For example:

   Command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
router bgp 65530

 bgp router-id 172.16.31.100

 network 0.0.0.0/0

 neighbor 172.16.31.254 remote-as 65531
```

4. Follow similar steps to configure the ingress side.
5. From vtysh verify that configuration is propagated to all cluster nodes, by entering:

   Command:

   ```
   ns# show running-config
   ```

6. Finally, log on to NSIP address of each cluster node and verify routes advertised from BGP peer:

   Command:

   ```
   > show route | grep BGP
   ```

Optimizing TCP Performance using TCP Nile

TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.

Congestion Control Strategies

The Transmission Control Protocol (TCP) has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NILE Algorithm

Citrix® Systems has developed a new congestion-control algorithm, NILE, a TCP optimization algorithm designed for high-speed networks such as LTE, LTE advanced and 3G. Nile addresses unique challenges caused by fading, random or congestive losses, link layer retransmissions and carrier aggregation.

The NILE algorithm:

- Bases queue-latency estimates on round-trip time measurements.
- Uses a congestion-window-increase function that is inversely proportional to the measured queue latency. This method results in approaching the network congestion point more slowly than does the standard TCP method, and reduces the packet losses during congestion.
- Can distinguish between random loss and congestion based loss on the network by using the estimated queue latency.

The telecom service providers can use the NILE algorithm in their TCP infrastructure to:

- Optimize mobile and long-distance networks— The NILE algorithm achieves higher throughput compared to standard TCP. This feature is especially important for mobile and long-distance networks.
- Decrease application perceived latency and enhance subscriber experience— The Nile algorithm uses packet loss information to determine whether the transmission-window size should be increased or decreased, and uses queuing delay information to determine the size of the increment or decrement. This dynamic setting of transmission-window size decreases the application latency on the network.

To configure NILE support using the command line interface

At the command prompt, type the following:

```
set ns tcpProfile <name> [-flavor NILE]
```

Configuring NILE support using the configuration utility

1. Navigate to **System** > **Profiles** > **TCP Profiles** and click **TCP profiles**.
2. From the **TCP Flavor** drop-down list, select **NILE**.

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set ns tcpProfile tcpprofile1 -flavor NILE
```

Proportional Rate Recovery (PRR) Algorithm

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

TCP Fast Open (TFO)

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP's initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a NetScaler appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the NetScaler appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using the TFO mechanism, you can reduce an application's network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

How TFO works

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the NetScaler appliance can include data in the SYN-ACK segment even though it has not received the final ACK segment of the three-way handshake. This saves up to one full round-trip compared to a normal TCP connection, which requires a three-way handshake before any data can be exchanged.

A client and a backend server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the NetScaler appliance.
2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client's IP address under a secret key) and responds to the client with a SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached Fast Open Cookie (as a TCP option) along with HTTP data.
5. The NetScaler appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with a SYN-ACK, TFO Cookie, and HTTP Response.

Note: If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the NetScaler appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.
2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the backend server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same backend server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the backend server.
6. The backend server acknowledges the event with both data and a SYN.

Note: If the server acknowledges the event with only a SYN segment, the NetScaler appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.

Configuring TCP Fast Open

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

To enable or disable TFO by using the command line

At the command prompt, type one of the following commands to enable or disable TFO in a new or existing profile.

Note: The default value is DISABLED.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED

set tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED

unset tcpprofile <TCP Profile Name> - tcpFastOpen
```

Examples:

add tcpprofile Profile1 – tcpFastOpen Set tcpprofile Profile1 – tcpFastOpen Enabled unset tcpprofile Profile1 – tcpFastOpen

To set TCP Fast Open cookie timeout value by using the command line interface

At the command prompt, type:

```
set tcpparam –tcpfastOpenCookieTimeout <Timeout Value>
```

Example:

```
set tcpprofile –tcpfastOpenCookieTimeout 30secs
```

To configure the TCP Fast Open by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **TCP Fast Open** checkbox.
3. Click **OK** and then **Done**.

To Configure the TCP Fast Cookie timeout value by using the GUI

Navigate to **Configuration** > **System** > **Settings** > **Change TCP Parameters** and then **Configure TCP Parameters** page to set the TCP Fast Open Cookie timeout value.

TCP Hystart

A new TCP profile parameter, hystart, enables the Hystart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If congestion is detected, Hystart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.

Configuring TCP Hystart

To use the Hystart feature, enable the Cubic Hystart option in the relevant TCP profile.

To configure Hystart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable Hystart in a new or existing TCP profile.

```
add tcpprofile <profileName> -hystart ENABLED

set tcpprofile <profileName> -hystart ENABLED

unset tcprofile <profileName> -hystart
```

Examples:

```
add tcpprofile Profile1 – tcpFastOpen

Set tcpprofile Profile1 – tcpFastOpen Enabled

unset tcpprofile Profile1 – tcpFastOpen
```

To configure Hystart support by using the GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Cubic Hystart** check box.
3. Click **OK** and then **Done**.

Optimization Techniques

TCP uses the following optimization techniques and methods for optimized flow controls.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Policy based TCP Profile Selection

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server's traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

Configuring Policy Based TCP Profile Selection

Configuring policy based TCP profile selection consists of the following tasks:

- Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.
- Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
- Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your NetScaler appliance can distinguish the connections and bind the correct AppQoE action to each policy.
- Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface:

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

```
enable ns feature appqoe

show ns feature
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind a TCP profile while creating an AppQoE action using the command line interface

At the command prompt, type the following AppQoE action command with tcpprofiletobind option.

Binding a TCP Profile:

```
add appqoe action <name> [-priority <priority>] [-respondWith ( ACS | NS )
[<CustomFile>] [-altContentSvcName <string>] [-altContentPath <string>] [-
maxConn <positive_integer>] [-delay <usecs>]] [-polqDepth
<positive_integer>] [-priqDepth <positive_integer>] [-dosTrigExpression
<expression>] [-dosAction ( SimpleResponse |HICResponse )] [-
tcpprofiletobind <string>]

show appqoe action
```

To configure an AppQoE policy by using the command line interface

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:

```
bind cs vserver cs1 -policyName <appqoe_policy_name> -priority <priority>

bind lb vserver <name> - policyName <appqoe_policy_name> -priority
<priority>

bind cr vserver <name> -policyName <appqoe_policy_name> -priority
<priority>
```

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle ENABLED
-maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minRTO 500 -slowStartIncr 1
-bufferSize 4194304 -flavor BIC -KA ENABLED -sendBuffsize 4194304
-rstWindowAttenuate ENABLED -spoofSynDrop ENABLED -dsack enabled -frto
ENABLED -maxcwnd 4000000 -fack ENABLED -tcpmode ENDPOINT

add appqoe action appact1 -priority HIGH -tcpprofile tcp1

add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -action
appact1

bind lb vserver lb2 -policyName apppol1 -priority 1
-gotoPriorityExpression END -type REQUEST

bind cs vserver cs1 -policyName apppol1 -priority 1
-gotoPriorityExpression END -type REQUEST
```

Configuring Policy based TCP Profiling using the GUI

To enable AppQoE by using the GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Configure Advanced Features**.
3. In the **Configure Advanced Features** dialog box, select the **AppQoE** check box.
4. Click **OK**.

To configure AppQoE policy by using the GUI

1. Navigate to **App-Expert** > **AppQoE** > **Actions**.
2. In the details pane, do one of the following:
3. To create a new action, click **Add**.
4. To modify an existing action, select the action, and then click **Edit**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

5. In the **Create AppQoE Action** or the **Configure AppQoE Action** screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):
    a. Name—name
    b. Action type—respondWith
    c. Priority—priority
    d. Policy Queue Depth—polqDepth
    e. Queue Depth—priqDepth
    f. DOS Action—dosAction
6. Click **Create**.

To bind AppQoE policy by using the GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select a server and then click **Edit**.
2. In the **Policies** section and click (+) to bind an AppQoE policy.
3. In the **Policies** slider, do the following:
    a. Select a policy type as AppQoE from the drop-down list.
    b. Select a traffic type from the drop-down list.
4. In the **Policy Binding** section, do the following:
    a. Click **New** to create a new AppQoE policy.
    b. Click **Existing Policy** to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click **Bind** to the policy to the virtual server.
6. Click **Done**.

SACK Block Generation

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgement (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

Note: A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

Client Reneging

A NetScaler appliance can handle client reneging during SACK based recovery.

Memory checks for marking end_point on PCB is not considering total available memory

In a NetScaler appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

Unnecessary retransmissions due to missing SACK blocks

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers additional retransmissions from the server.

SNMP for number of connections bypassed optimization because of overload

The following SNMP ids have been added to a NetScaler appliance to track number of connections bypassed TCP optimization due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.13 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.

Dynamic Receive Buffer

To maximize TCP performance, a NetScaler appliance can now dynamically adjust the TCP receive buffer size.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Troubleshooting Guidelines

Technical Support

All troubleshooting and escalation queries require a recent NetScaler techsupport bundle, which captures current configuration, firmware version installed, log files, outstanding cores, and others.

Example:

```
show techsupport

showtechsupport data collector tool - $Revision: #5 $!

...
```

All the data will be collected under

```
...

Archiving all the data into "/var/tmp/support/
collector_P_192.168.121.117_18Jun2015_09_53.tar.gz" ....

Created a symbolic link for the archive with /var/tmp/support/support.tgz

/var/tmp/support/support.tgz  ---- points to ---> /var/tmp/support/
collector_P_192.168.121.117_18Jun2015_09_53.tar.gz
```

After a techsupport bundle has been generated, it might be copied using SCP.

Traces

NetScaler TCP optimization issues normally require NetScaler traces to troubleshoot properly. Note that one should try to capture traces under similar conditions, i.e. on the same cell, during the same time of day, using the same user equipment and application, and others.

The start nstrace and stop nstrace commands might be used to capture traces:

- It’s strongly recommended that the appropriate filter is used to avoid capturing extraneous, unnecessary packets on the trace. For instance use start nstrace -filter 'IP == 10.20.30.40' to

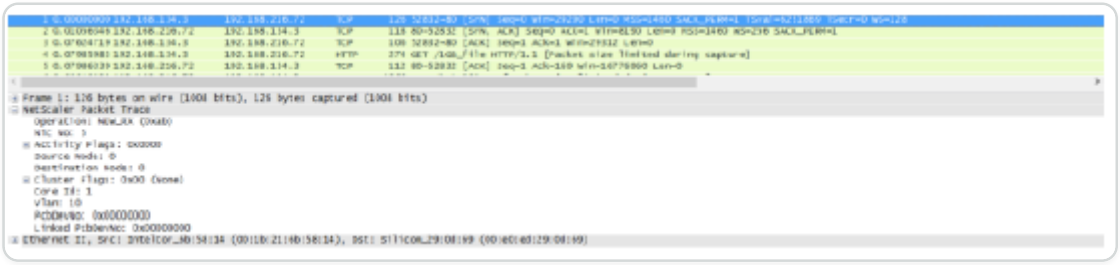
© 1997–2026 Citrix Systems, Inc. All rights reserved.

only capture packets being sent to or received from IP address 10.20.30.40, which is the user equipment IP address.

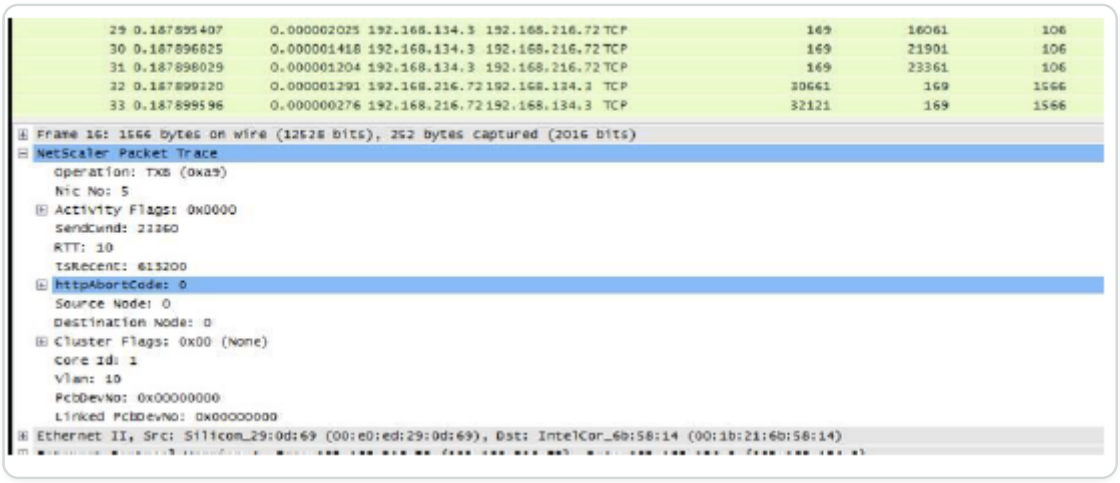
- Do not use the -tcpdump option, since it strips the nstrace headers which are required for debugging.

Trace Analysis

After a NetScaler trace has been captured, it might be viewed with Wireshark 1.12 or later. Verify that the captured traces include the appropriate NetScaler Packet Trace headers, as shown in the screen capture below:



The additional debug headers are also visible per the illustration below:



Connection Table

When the issue is related to TCP optimization and it can be reproduced or it's on-going, it is best to get also the connection table when the issue occurs from the primary T1 node.

To get the table you shall need to switch to the BSD shell and run the following command:

```
shell

...
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
nscli -U 127.0.0.1:nsroot:nsroot show connectiontable -detail full link
> /var/tmp/contable.log
```

NOTE

The command might be executed for a longer time and management CPU might be stressed at that time (depends on the number of connection table entries), but it's not service affecting.

Frequently Asked Questions

Timeouts

IMPORTANT

Before using *any nsapimgr* knob, consult with Citrix® Customer Support.

The following is a list of different idle connection timeouts that can be set on NetScaler T1 virtual servers and services. Idle timeout set for client or server connections at the vserver or service level are applicable only for the connections in TCP ESTABLISHED state and are idle.

- Load Balancing virtual server cltTimeout parameter specifies the time in seconds that a connection from a client to a Load Balancing virtual server must be idle, before the appliance closes the connection.
- Service svrTimeout parameter specifies the time in seconds that a connection from the appliance to a service or server must be idle, before the appliance closes the connection.
- Service cltTimeout parameter specifies the time in seconds that a connection from a client to a service must be idle, before the appliance closes the connection.

When a service is bound to a Load Balancing virtual server, then the cltTimeout for the Load Balancing virtual server takes precedence, and the service cltTimeout for service is ignored.

In case of there is not service bound to Load Balancing virtual server, global idle timeout, namely tcpServer, is used for server side connections. It can be configured as follows:

Command:

```
set ns timeout –tcpServer 9000
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Connections in other state have different timeout values:

- Half open connections idle timeout: 120 seconds (hardcoded value)
- TIME_WAIT connections idle timeout: 40 seconds (hardcoded value)
- Half close connections idle timeout. By default it is 10s and can be configured between 1s and 600s using the snippet

Command:

```
set ns timeout –halfclose 10
```

When half-close timeout is triggered, connection is moved to zombie state. When zombie timeout expires, zombie cleanup kicks in and T1 sends RST on both client and server side for given connection by default.

- Zombie timeout: Interval at which the zombie cleanup process must run to clean up inactive TCP connections. Default timeout value is 120s and can be configured between 1s and 600s.

Command:

```
set ns timeout –zombie 120
```

Maximum Segment Size Table

A NetScaler T1 appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted. Specific function is enabled by default without option to disable.

However, there is caveat as standard SYN cookies limit connections to the use of only eight Maximum Segment Size (MSS) values. If connection MMS does not match with any predefined value, it will pick up the next available lower value towards both client and server side.

The predefined TCP Maximum Segment Size (MSS) values are the following and can be configured through a new nsapimgr knob.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1460	1440	1330	1220	956	536	384	128

The new MSS table:

- Need not contain Jumbo-Frame support. Even though by default 8 values are reserved in the MSS table for jumbo frames, the table settings can be modified to include standard Ethernet-sized frames only.
- Should have 16 values
- Should have values in descending order
- Should include 128 as the last value

If the new MSS table is valid, the table is stored and the old values are switched out at the SYN-cookie rotation time. Otherwise the new table returns an error. Changes are applied to new connections while existing connections preserve the old MSS table until the connections expire or are terminated.

To display the current MSS table in a NetScaler appliance, type the following command.

Command:

```
>shell

#nsapimgr -d mss_table
```

Example:

```
#nsapimgr -d mss_table

MSS table

{9176,9156,8192,7168,6144,4196,3072,2048,1460,1440,1330,1212,956,536,384,1
28}
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Done.
```

To change the mss table, type the following command:

Command:

```
>shell

#nsapimgr -s mss_table=<16 comma seperated values>
```

Example:

```
#nsapimgr -ys
mss_table=9176,9156,8192,7168,6144,4196,3072,2048,1460,1400,1330,1212,956,
536,384,128

# nsapimgr -d mss_table

MSS table

{9176,9156,8192,7168,6144,4196,3072,2048,1460,1400,1330,1212,956,536,384,1
28}

Done.
```

An example using standard Ethernet-sized values is depicted below:

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
#nsapimgr -ys
mss_table=1460,1440,1420,1400,1380,1360,1340,1320,1300,1280,1260,1212,956,
536,384,128

# nsapimgr -d mss_table

MSS table

{1460,1440,1420,1400,1380,1360,1340,1320,1300,1280,1260,1212,956,536,384,1
28}

Done.
```

To make this change permanent even after the NetScaler appliance restarts, include the command `#nsapimgr -ys mss_table=<16 comma seperated values>` in the "/nsconfig/rc.netscaler" file. If the "rc.netscaler" file doesn't exist, create it under the "/nsconfig" folder, and then append the command.

Memory Overload Protection

A NetScaler Packet Processing Engine (PPE) starts bypassing connections from TCP optimization if the memory in use by that one PPE is more than a specified high watermark value. If a PPE memory utilization goes above ~2.6GB, then it starts bypassing *any new* connections from optimization. The existing connections (ones admitted for optimization previously) continues getting optimization. This watermark value has been purposefully selected and is not recommended for tuning.

NOTE

If you believe that there is a good reason to change that watermark value, contact Customer Support.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for Happy Eyeballs Clients

If the NetScaler appliance receives a SYN for a destination for which the state is unknown, the appliance first checks the reachability of the server and then acknowledges the client. This probing mechanism enables clients with dual IP stacks to discover the reachability of dual-stack internet servers. If the client discovers that both IPv6 and IPv4 access are available, it establishes a connection to the server that responds more quickly, and resets the other. For the connection for the NetScaler appliance receives a reset, it will reset the corresponding server side connection.

Note: This feature has no user configurable TCP settings to be disabled/enabled on the NetScaler appliance.

For more information on Happy Eyeballs support, see RFC 6555.

NetScaler Video Optimization

WARNING:

Video optimization is supported only for a forward proxy telco solution. Do not enable video optimization for any other type of use case. Video optimization is not supported on admin partition and cluster topologies.

The NetScaler appliance provides optimization techniques and capabilities to optimization ABR video traffic for video traffic over mobile networks. This improves user experience and reduces the overall network bandwidth consumption.

The section includes the following topics:

- Getting Started
- Licensing
- Configuring Video Optimization over TCP
- Configuring Video Optimization over UDP

Getting Started

Media files have been driving an increasing amount of traffic over mobile networks, and migration to faster networking technologies has dramatically increased the volume of encrypted video traffic. The traditional media delivery technology (Progressive Download) is failing to deliver acceptable quality of experience (QoE) at a high transmission rate. This has led to the introduction of the Adaptive Bit Rate (ABR) protocol. It can adapt the streaming bit rate to the available network

© 1997–2026 Citrix Systems, Inc. All rights reserved.

bandwidth and restrict streaming quality to match the capability of the handset receiving the video. However, the ABR protocol does not work as well in mobile networks as it does over the internet. Mobile operators must, therefore, optimize ABR traffic.

A NetScaler appliance has unique capabilities to detect incoming video traffic and selectively optimize ABR videos.

How NetScaler Video Optimization Works

A NetScaler appliance can identify and optimize encrypted ABR traffic (including Facebook video traffic) over TCP, and YouTube ABR traffic over QUIC. The appliance has the following capabilities:

1. Detect Progressive Download (PD) videos over HTTP.
2. Detect and optimize ABR videos over HTTP.
3. Detect and optimize ABR videos over HTTPS.
4. Detect and optimize YouTube ABR videos over QUIC.

Also, the appliance uses the following support domains for detecting video traffic over TCP and QUIC protocols.

- Unencrypted ABR videos over TCP. Appliance detects all standard compliant video streaming web sites. The appliance detects ABR sessions by inspecting the response video payload header, URL, and HTTP headers.
- Encrypted ABR video over TCP. Appliance detects ABR sessions using a generic and heuristic algorithm based on domain, SSL header and traffic patterns. Using this, the appliance has a built-in support to detect top video web sites, with 95 percent accuracy and we continue to add support for new video types. NetScaler also has a program to provide additional verification for top encrypted ABR sites for a region or country to ensure network coverage.
- Encrypted ABR videos over QUIC. The appliance detects ABR sessions for QUIC based video provider, such as YouTube. The detection algorithm is on the basis of a heuristic leveraging the QUIC headers and domain. NetScaler will continue to add support for newer video sites using QUIC.

Benefits

Optimizing the ABR video traffic can provide the following benefits:

- Manage the network during congestion in peak hours.
- Improve video play consistency and reduce video stalling.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Enable new video service offerings (for example, Binge-on video services).
- Enable customers to select the best sustainable video quality.
- Provide a consistent user experience for the subscriber.

Video Optimization over TCP

NetScaler optimization of ABR traffic over TCP works as follows:

1. HTTP or HTTPS traffic that the appliance receives over TCP is sent to the corresponding load balancing virtual server.
2. The built-in detection policies bound to the virtual server combined with other proprietary detection algorithms evaluate the traffic.
3. The policies use a set of built-in video detection signatures to detect the video type. The policy that matches traffic applies an action that categorizes the video type as one of the following:
    a. Clear-text PD
    b. Clear-text ABR
    c. Encrypted ABR

© 1997–2026 Citrix Systems, Inc. All rights reserved.

d. Other

4. The optimization policies bound to the same virtual server evaluate the traffic and determine the optimization bit rate to apply to the traffic.
5. The optimization bit rate is applied if the traffic is either clear-text ABR or encrypted ABR.

A mobile service provider can improve the quality of experience (QoE) by setting the download speed for 2G, 3G, and 4G mobile traffic. This reduces the video start times or buffering events. Optimization can also reduce the amount of network bandwidth consumed by video sessions.

The optimization techniques include dynamic burst control and random sampling.

Dynamic Burst Control

NetScaler ABR optimization adapts dynamically to changing network conditions. It allows an initial burst rate of 1.3 times the configured pacing rate for 15 seconds. The initial burst rate applies to the beginning of every optimized ABR video session, even when multiple sessions use the same TCP connection or group of TCP connections.

The appliance also supports recovery bursts in the event that the bit rate supported by the network drops below the configured pacing rate. For example, if the effective bit rate drops at the 7th second and recovers at 15th second of the initial burst, the appliance recovers the loss during the next burst cycle. By doing so, the appliance dynamically optimizes the network bandwidth for all subscribers so that the quality of video remains consistent per pixel.

Note: When a recovery burst happens during an initial burst, the pacing bit rate must not exceed the maximum recovery-burst and initial-burst rates (you must not add the Recovery Burst factor on top of the Initial Burst factor). Otherwise, it might be so fast that the media player shifts to a higher quality mode. However, if necessary, you can extend the duration of the Initial Burst to compensate the unused bandwidth.

Random Sampling

To estimate the savings from video optimization, the NetScaler appliance implements random sampling. With this technique, the appliance randomly selects a configurable percentage of the detected video traffic (the random sampling parameter is an integer number ranging from 0 to 100, so less than 1 percent is not possible). These randomly selected and non-optimized transactions (and sessions) become a reference group, and they are identified in the transaction logs (along with other characteristics, such as byte size and timer fields. The characteristics of the optimized sessions are also logged, and the reporting engine compares statistics of the optimized and

© 1997–2026 Citrix Systems, Inc. All rights reserved.

reference groups to estimate the savings from optimization (including the savings from ABR Optimization).

Video Optimization over UDP

Google has introduced a new transport protocol called QUIC. Google's QUIC protocol is very similar to TCP+TLS+HTTP/2 and is implemented on top of UDP. NetScaler can detect YouTube ABR videos streamed over the QUIC protocol, and apply ABR video optimization in a similar way as ABR over TCP.

Licensing

The Video Optimization feature works on Telco platforms with the purchase of a basic CBM license and CBM Premium license and for other NetScaler platforms, the feature works with the purchase of a CNS Premium license. Before you configure the video optimization feature, your appliance must have a suitable license.

License support for Telco platforms:

- **CBM_TXXX_SERVER_Retail.lic**
- **CBM_TPRE_SERVER_Retail.lic**
- **CNS_WEBF_SSERVER_Retail.lic**

Where XXX is the throughput, for example, NetScaler T1000.

License support for other NetScaler platforms:

- **CNS_XXX_SERVER_PLT_Retail.lic**

Where XXX is the throughput.

To upload a Premium license file, follow the steps given below:

1. A valid license file should be installed on the NetScaler appliance. The license should support at least as many Gbps as the expected maximum Gi-LAN throughput.

   License files should be copied through an SCP client to the /nsconfig/license of the appliance, as shown in the screen capture below.

   ```
   > shell ls /nsconfig/license/

   CNS_V3000_SERVER_PLT_Retail.lic ssl
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Do a warm restart to apply for the new license, as shown in the screen capture below.

```
> reboot -warm

Are you sure you want to restart NetScaler (Y/N)? [N]:y

 Done
```

3. After the restart completes, verify that the license has been properly applied, by using the show license CLI.

In the example below a Premium license with Premium edition has been successfully installed.

```
> show license

              License status:

                                    Video Optimization: YES

                                                ...

                                 Model Number ID: 110050

                                    License Type: Premium License
```

Configuring Video Optimization over TCP

WARNING:

As part of video optimization, the video pacing functionality is deprecated and will be removed from the NetScaler appliance in forthcoming releases.

To optimize video traffic over TCP, begin by enabling the video optimization feature. The appliance then activates the built-in detection policies to detect the incoming video traffic and identify the type of video. User configurable optimization policies for each video type specify the optimization bit rate needed for optimizing the traffic.

Configuring Video Optimization over TCP by using the CLI

To configure video optimization on a NetScaler appliance, you perform the following tasks:

1. Enable the video optimization feature.
2. Add virtual servers for HTTP and HTTPS traffic.
3. Bind all the built-in detection policies to a load balancing virtual server for HTTP traffic.
4. Bind all the built-in detection policies to an SSL-bridge load balancing virtual server for HTTPS traffic.
5. Add the desired optimization policies for HTTP and HTTPS traffic.
6. Bind optimization policies to a load balancing virtual server for HTTP Traffic.
7. Bind optimization policies to an SSL-bridge load balancing virtual server for HTTPS traffic.

Enabling Video Optimization

If you want the NetScaler appliance to detect, optimize, and report video traffic, you must enable the Video Optimization feature and set optimization to ON. After enabling the feature you can use built-in detection policies to identify the incoming video traffic, and you can configure optimization policies to optimize encrypted ABR traffic. To optimize ABR video traffic, you must configure the download bit rate (also called the *pacing rate*).

You must also enable the load balancing feature, and if you want to use video optimization for HTTPS traffic you must enable the SSL feature.

To enable the video optimization feature

At the command prompt, type the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
enable ns feature VideoOptimization
```

NOTE

If you want to monitor the video optimization performance and video insight reports you must enable the AppFlow feature and then access the Video Analytics feature on NetScaler Application Delivery Management (ADM). For more information, see Video Insight documentation.

Creating Virtual Servers for HTTP and HTTPS Video Traffic

A NetScaler appliance uses different virtual servers for detecting and optimizing the different types of incoming video traffic. The appliance supports the following types of virtual servers for TCP traffic.

- **HTTP Load Balancing virtual server**. For detecting HTTP video traffic, the appliance uses an HTTP load balancing virtual server. It manages HTTP video requests that the appliance receives from clients.
- **SSL-Bridge Load Balancing virtual server**. To detect encrypted video traffic, you must configure an SSL bridge virtual server on the appliance.

To add an HTTP Load Balancing virtual server for detecting HTTP video traffic

At the command prompt, type the following:

```
add lb vserver <name> HTTP * 80 -persistenceType NONE
```

Example:

```
add lb vserver ProxyVserver-HTTP HTTP * 80 -persistenceType NONE
-cltTimeout 120
```

To add an SSL Bridge virtual server for detecting HTTPS video traffic

At the command prompt, type the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add lb vserver <name> SSL_BRIDGE * 443 -persistenceType NONE
```

Example:

```
add lb vserver ProxyVserver-SSL SSL_BRIDGE * 443 -persistenceType NONE
-cltTimeout 180
```

Binding Built-In Detection Policies to an HTTP Load Balancing Virtual Server

To detect video traffic over an HTTP connection, you must bind all the built-in detection policies to a load balancing virtual server. You must bind the policies to either request-time or response-time processing, depending on the policy type.

NOTE:

The `ns_videoopt_http_body_detection` video optimization policy does not support the `CONNECT` HTTP request method.

To bind detection policies for different video types to an HTTP load balancing virtual server

At the command prompt, type the appropriate command for each type. The available commands are:

```
bind lb vserver <name> -policyName ns_videoopt_http_abr_netflix -priority
<integer> -type (REQUEST | RESPONSE)

bind lb vserver <name>   -policyName ns_videoopt_http_abr_netflix2
-priority <integer> -type (REQUEST | RESPONSE)

bind lb vserver <name>   -policyName ns_videoopt_http_abr_youtube
-priority <integer>  -type (REQUEST | RESPONSE)
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lb vserver <name>    -policyName ns_videoopt_http_pd_youtube
-priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver <name>    -policyName ns_videoopt_http_pd_youtube2  -
priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver  <name>   -policyName ns_videoopt_http_pd_youtube3
-priority <integer>  -type (REQUEST | RESPONSE)

bind lb vserver  <name>  -policyName ns_videoopt_http_abr_generic
-priority <integer> -type (REQUEST | RESPONSE)
```

Example:

```
bind lb vserver ProxyVserver-HTTP    -policyName
ns_videoopt_http_abr_netflix -priority 400  type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName
ns_videoopt_http_abr_netflix2 -priority 500 -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName
ns_videoopt_http_abr_youtube -priority 600  -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName
ns_videoopt_http_pd_youtube -priority 800  -type RESPONSE

bind lb vserver ProxyVserver-HTTP    -policyName
ns_videoopt_http_pd_youtube2 -priority 900 -type RESPONSE
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lb vserver  ProxyVserver-HTTP   -policyName
ns_videoopt_http_pd_youtube3 -priority 1000 -type REQUEST

bind lb vserver  ProxyVserver-HTTP   -policyName
ns_videoopt_http_abr_generic -priority 1100 -type RESPONSE
```

Binding the HTTP Body Content Detection Policy to Load Balancing Virtual Server

To detect video traffic over HTTP, you must bind the body content detection policy to the load balancing virtual server. You can use the following command:

```
bind lb vserver <name> -policyName ns_videoopt_http_body_detection
-priority <integer> -type (REQUEST | RESPONSE)
```

Example:

```
bind lb vserver ProxyVserver-HTTP -policyName
ns_videoopt_http_body_detection -priority 1500 -type REQUEST
```

Binding Built-In Detection Policies to an SSL-Bridge Load Balancing Virtual Server

To detect video traffic over an HTTPS connection, you must bind built-in detection policies to an SSL Bridge load balancing virtual server.

To bind a detection policy to an SSL bridge load balancing virtual server

At the command prompt, type the appropriate command for each type. The available commands are:

```
bind lb vserver <name> -policyName ns_videoopt_https_abr_netflix -priority
<positive_integer> -type (REQUEST | RESPONSE)
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lb vserver <name> -policyName ns_videoopt_https_abr_youtube -priority
<positive_integer> -type (REQUEST | RESPONSE)

bind lb vserver <name> -policyName ns_videoopt_https_abr_generic -priority
<positive_integer> -type (REQUEST | RESPONSE)
```

Example:

```
bind lb vserver ProxyVserver-SSL -policyName ns_videoopt_https_abr_netflix
-priority 120 -type REQUEST

bind lb vserver ProxyVserver-SSL -policyName ns_videoopt_https_abr_youtube
-priority 140 -type REQUEST

bind lb vserver ProxyVserver-SSL -policyName ns_videoopt_https_abr_generic
-priority 150 -type REQUEST
```

Adding Optimization Policies for Pacing ABR traffic

To optimize ABR traffic, you have to configure optimization policies and the associated actions. You then bind the policies to the same load balancing virtual servers to which you bound the detection policies. For each policy, create the action first, so that you can include it when you create the policy.

To add an optimization action

At the command prompt, type:

```
add videooptimization pacingaction <action Name> -rate <integer> [-comment
<string>]
```

Where the **rate** parameter specifies the rate in Kbps at which to send the traffic (the pacing rate).

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add videooptimization pacingaction MyOptAct2000 -rate 2000
```

To add an optimization policy

At the command prompt, type:

```
add videooptimization pacingpolicy <name> -rule <expression> -action
<string>
```

Example:

```
add videooptimization pacingpolicy myOptPolicy2000 -rule TRUE -action
MyOptAct2000
```

Binding Optimization Policies to an HTTP Load Balancing Virtual Server

To optimize ABR video traffic over an HTTP connection, you must bind the optimization policies to a load balancing virtual server to which the detection policies are bound.

To bind an optimization policy to a Load Balancing virtual server

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority
<positive_integer> -type  (REQUEST | RESPONSE)
```

Example:

```
bind lb vserver ProxyVserver-HTTP -policyName myOptPolicy2000 -priority
3400 -type  REQUEST
```

Binding Optimization Policies to SSL-bridge Virtual Servers

To optimize ABR video traffic over an HTTPS connection, you must bind the optimization policies to the SSL Bridge virtual server to which the built-in detection policies are bound.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind an optimization policy to SSL Bridge virtual server for pacing encrypted traffic

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority
<positive_integer> -type  (REQUEST |RESPONSE)
```

Example:

```
bind lb vserver ProxyVserver-SSL -policyName myOptPolicy2000 -priority
3400 -type  REQUEST
```

Setting video optimization pacing parameters

The CLI enables you to set the video optimization pacing parameters, such as random sampling percentage.

To set the random sampling percentage

At the command prompt, type the following command:

```
set videooptimization parameter –RandomSamplingPercentage <realNumber>
```

Where, a realNumber is a value from 0.0 to 100.0.

Example:

```
set videooptimization parameter -RandomSamplingPercentage 50
```

Configuring Video Optimization over TCP by using the GUI

The GUI enables you to:

- Enable video optimization feature.
- Create HTTP load balancing virtual server.
- Create SSL-bridge load balancing virtual server.
- Bind built-in detection policies to HTTP load balancing virtual server.
- Bind built-in detection policies to SSL-bridge load balancing virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Create an optimization policy.
- Create an optimization action.
- Configuring optimization pacing parameter.
- Bind optimization policy to load balancing virtual server for HTTP traffic.
- Bind optimization policy to SSL-bridge load balancing virtual server for HTTPS traffic.

To enable video optimization feature

1. In the navigation pane, expand **System**, and then click **Settings**.
2. On the **Settings** page, click the **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select the **Video Optimization** check box.
4. Click **OK**, and then click **Close**.

To create load balancing virtual server for HTTP traffic

1. Sign in to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the Load Balancing Virtual Server screen, set the following parameters:
    a. **Name**. Name of the load balancing virtual server.
    b. **Protocol**. Select protocol type as HTTP
    c. **IP Address Type**. IP address type: IPv4 or IPv6.
    d. **IP Address**. IPv4 or IPv6 address assigned to the virtual server.
    e. **Port**. Port number of the virtual server.
4. Click **OK** to continue with configuration of other, optional, parameters. For more information, see Creating a Virtual Server.
5. Click **Create** and **Close**.

To create load balancing virtual server for HTTPS traffic

1. Sign in to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. **Name**. Name of the load balancing virtual server.

b. **Protocol**. Select protocol type as SSL-bridge.

c. **IP Address Type**. IP address type: IPv4 or IPv6.

d. **IP Address**. IPv4 or IPv6 address assigned to the virtual server.

e. **Port**. Port number of the virtual server.

4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.
5. Click **Create** and then **Close**.

To bind a built-in detection policy to a load balancing virtual server

1. Sign in to the NetScaler appliance and navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the load balancing virtual server and click **Edit**.

a. In the **Advanced Setting** section, click **Policies**.

b. In the **Policies** section, click the **+** icon to access the **Policies** slider.

c. In the **Policies** section, set the following parameters.

d. Choose Policy. Select a video optimization detection policy from the drop-down list.

e. Choose Type. Select the policy type as Request.

f. Click **Continue**.

3. Select the video detection policy from the list and click **Close**.

To bind a built-in detection policy to a SSL-bridge load balancing virtual server

1. Log on to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.

a. Choose Policy. Select video optimization detection policy from the drop-down list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. Choose Type. Select the policy type as Request.

6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

To create a video optimization action

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Actions**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Action** page, set the following parameters.
   a. **Name**. Name of the optimization action.
   b. **ABR Optimization Rate (Kbps).** Pacing rate at which to send the ABR video traffic. The default rate for ABR optimization is 1000 Kbps. The minimum value is 1, and the maximum value is 2147483647.
   c. **Comment**. A short description of the action.
4. Click **Create** and **Close**.

To create a video optimization policy

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Policies**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Policy** page, set the following parameters.
   a. **Name**. Name of the optimization policy
   b. **Expression**. Custom regex expressions that implement the policy.
   c. **Action**. Optimization action associated with the policy to handle the incoming video traffic.
   d. **UNDEF Action.** Undefined event if the incoming request does not match the optimization policy.
   e. **Comment**. A short description of the policy.
   f. **Log Action.** Select the audit log action that creates the desired log messages.
4. Click **Create**, and then click **Close.**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To set video optimization pacing parameters

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization.**
2. In the **Video Optimization** page, click **Change Video Optimization Settings** link.
3. In the **Video Optimization Settings** page, set the following parameter.
    a. **Random Sampling Percentage (%)**. Percentage of packets selected for random sampling.
4. Click **OK** and **Close**.

To bind a video optimization policy to an HTTP load balancing virtual server

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.
2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. Set the following parameters.
    a. **Bind Point**. The point at which to apply the optimization policy during request or response processing.
    b. **Connection Type**. Connection type as Request or Response.
    c. **Virtual Server**. The load balancing virtual server to which to bind the policy.
    d. Click **Continue**.
4. In the **Bind Point** section, do one of the following:
    a. Select a policy from the list.
    b. Click **Add Binding** to access the **Policies Binding** slider.
        i. Select an existing policy or add a new policy.
        ii. Enter binding details and click **Bind**.
5. Click **Close**.

To bind a video optimization policy to an SSL-bridge load balancing virtual server

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. On the **Video Optimization Policy Manager** page, set the following parameters.
    a. Bind Point. The point at which to apply the optimization policy during request/response processing.
    b. Connection Type. Connection type as Request or Response.
    c. Virtual Server. The SSL-bridge load balancing virtual server to which to bind the policy.
4. Click **Continue**.
5. In the **Bind Point** section, do one of the following:
    a. Select a policy binding from the list.
    b. Click **Add Binding** to access the **Policies Binding** slider.
        i. Select an existing policy or add a new policy.
        ii. Enter binding details and click **Bind**.
6. Click **Close**.

Configuring Video Optimization over UDP

To optimize QUIC ABR video traffic over UDP, begin by enabling the video optimization feature. After you complete the configuration, the appliance detects QUIC based ABR video traffic and applies the optimization bit rate that is configured on the appliance.

Configuring video optimization for QUIC by using the CLI

To configure video optimization for QUIC video traffic over UDP, you must perform the following tasks:

1. Enable Video Optimization.
2. Create a QUIC service.
3. Create a QUIC load balancing virtual server.
4. Bind QUIC web service to the loading balancing virtual server.
5. Create video optimization policy for pacing QUIC based UDP traffic.
6. Bind optimization policy to a QUIC based load balancing virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Enabling video optimization for QUIC traffic

If you want the NetScaler appliance to detect, optimize, and report video traffic, you must enable the Video Optimization feature and set optimization ON.

NOTE

If you want to use video optimization for QUIC traffic, you must enable the load balancing and AppFlow® features.

To enable the video optimization

At the command prompt, type the following command:

```
enable ns feature VideoOptimization
```

Creating a service for QUIC traffic

A NetScaler appliance uses a QUIC service for the load balancing virtual server to connect to the egress router in the static routing mode.

NOTE

Currently, dynamic routing is not supported.

To create a load balancing web service for QUIC video traffic

At the command prompt, type:

```
add service <name> <router-IP> <serviceType> <port> -usip yes
-useproxyport  [yes | no]
```

Example:

```
add service svc-quic 10.102.29.200 QUIC 443 –usip yes –useproxyport no

where IP address is the internet router address.
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Creating a load balancing virtual server for QUIC traffic

A NetScaler appliance uses a load balancing virtual server for detecting and optimizing QUIC video traffic over UDP.

To create a load balancing virtual server for QUIC video traffic

At the command prompt, type:

```
add lb vserver <name> <serviceType> <ip> <port> -m MAC
```

Example:

```
add lb vserver vs-quic QUIC * 443 -persistenceType NONE -m MAC -cltTimeout
120
```

Binding a QUIC web service to the load balancing virtual server

After you have created the web services and load balancing virtual server for QUIC traffic, you must bind the services to the virtual server.

To bind a web service to load balancing virtual server for QUIC video traffic

At the command prompt, type:

```
bind lb vserver <name> <serviceName>
```

Example:

```
bind lb vserver vs-quic svc-quic
```

Creating Video Optimization Policy for QUIC based UDP traffic

To optimize QUIC based UDP traffic, you have to configure optimization pacing policies and its actions. You must then, bind the policies to QUIC based load balancing virtual servers. For each policy, create an action first so that you can associate it to the policy.

To add an optimization action

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add videooptimization pacingaction <action Name> -rate <integer> [-comment
<string>]
```

Where, the **rate** parameter specifies the rate in Kbps at which to send the traffic (the pacing rate).

Example:

```
set videooptimization parameter -QUICPacingRate 1000
```

where 1000 represents the desired pacing rate in Kbits/sec.

To add an optimization policy

At the command prompt, type:

```
add videooptimization pacingpolicy <name> -rule <expression> -action
<string>
```

Example:

```
add videooptimization pacingpolicy myOptPolicy2000 -rule TRUE -action
MyOptAct2000
```

Binding Optimization Policies to a QUIC Load Balancing Virtual Server

To optimize QUIC video traffic over a UDP connection, you must bind the optimization policies to a QUIC load balancing virtual server.

To bind an optimization policy to a QUIC Load Balancing virtual server

At the command prompt, type the following command:

```
bind lb vserver <name> -policyName <policy_name> -priority
<positive_integer> -type (REQUEST)
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

The pacing policies must be bound to a QUIC load balancing virtual server only at request time.

Example:

```
bind lb vserver vs-quic -policyName myOptPolicy2000 -priority 3400 -type
 REQUEST
```

Configuring video optimization for QUIC by using the GUI

To configure the feature on the appliance through the GUI, you must perform the following tasks:

1. Enable video optimization
2. Configure a QUIC servers
3. Configure QUIC service
4. Configure a QUIC load balancing virtual server
5. Bind the QUIC web service to the load balancing virtual server
6. Create optimization policy.
7. Create optimization action.
8. Configuring optimization pacing parameter.
9. Bind optimization policy to load balancing virtual server for QUIC traffic.

To enable video optimization

1. Log on to the NetScaler appliance and navigate to **System** > **Settings.**
2. On the details page, select **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select the **Video Optimization** check box.

To create a QUIC servers

1. Log on to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Servers** screen.
2. In the details pane, click **Add**.
3. On the **Create Server** page, set the following parameters:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Name. Name of the QUIC server.

b. IP address. IP address of the QUIC server

c. Traffic Domain. Domain name of the server.

d. Enabling after creating. Initial state of the server.

e. Comments. Brief information about the server.

4. Click **Create.**

To create a QUIC service

1. Log on to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Services screen**.
2. In the details pane, click **Add**.
3. On the **Load Balancing Service** page, set the following parameters:

   a. **Service Name**. Name of the QUIC service.

   b. **IP address**. IP address assigned to the QUIC service.

   c. **Protocol**. Select protocol as QUIC.

   d. **Port**. Port number of the web service.

4. Click **OK** to continue. You can then configure other, optional, parameters. For more, see Configuring Services.
5. Once you configure the optional parameters, click **OK** and **Close**.

To create a load balancing virtual server

1. Log on to the NetScaler appliance and navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page, set the following parameters:

   a. **Name**. Name of the load balancing virtual server.

   b. **Protocol**. The protocol used by the service to send QUIC requests.

   c. IP Address Type. IP address type: IPv4 or IPv6.

   d. **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.

   e. **Port**. Port number of the virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Click OK to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.

To bind a load balancing virtual server to a QUIC service

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click **Services and Service Groups** to access the **Load Balancing Virtual Server Service Binding** screen.
3. Select a QUIC based web service and click **Bind**.
4. Click **Done**.

To bind a load balancing virtual server to a QUIC service

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, and select a virtual server.
2. Click **Services and Service Groups** to access the **Load Balancing Virtual Server Service Binding** screen.
3. Select a QUIC based web service and click **Bind**.
4. Click **Done**.

To create a video optimization action for QUIC traffic

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Actions**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Action** page, set the following parameters.
    a. **Name**. Name of the optimization action.
    b. **ABR Optimization Rate (Kbps).** Pacing rate at which to send the ABR video traffic. The default rate for ABR optimization is 1000 Kbps. The minimum value is 1, and the maximum value is 2147483647.
    c. **Comment**. A short description of the action.
4. Click **Create** and **Close**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To create a video optimization policy for QUIC traffic

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Pacing** > **Policies**.
2. In the details pane, click **Add**.
3. On the **Create Video Optimization Pacing Policy** page, set the following parameters.
    a. Name. Name of the optimization policy
    b. Expression. Custom regrex expressions that implement the policy.
    c. Action. Optimization action associated with the policy to handle the incoming video traffic.
    d. UNDEF Action. Undefined event if the incoming request does not match the optimization policy.
    e. Comment. A short description of the policy.
    f. Log Action. Select the audit log action that creates the desired log messages.
4. Click **Create**, and then click **Close**.

To bind a video optimization policy to an QUIC load balancing virtual server

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization**.
2. On the **Video Optimization** page, click the **Video Optimization Pacing Policy Manager** link.
3. On the **Video Optimization Policy Manager** page, set the following parameters.
    a. Bind Point. The point at which to apply the optimization policy during request processing. **Note**: The pacing policies must be bound to a QUIC load balancing virtual server only at request time.
    b. Connection Type. Connection type as Request or Response.
    c. Virtual Server. The load balancing virtual server to which to bind the policy.
4. Click **Continue**.
5. In the **Bind Point** section, do one of the following:
    a. Select a policy from the list.
    b. Click **Add Binding** to access the **Policies Binding** slider.
        i. Select an existing policy or add a new policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

ii. Enter binding details and click **Bind**.

6. Click **Close**.

NetScaler URL Filtering

NOTE:

URL categorisation in the URL filtering feature is deprecated in this release.

URL Filtering provides policy-based control of websites by using the information contained in URLs. This feature helps network administrators monitor and control user access to malicious websites on mobile networks.

As an administrator, you can configure a URL filtering policy by using either the URL Categorization feature or the URL List feature.

URL List. Controls access to blacklisted websites and webpages by blocking access to URLs that are in a URL set imported into the appliance.

URL Categorization. Controls access to websites and webpages by filtering traffic based on a predefined list of categories.

URL List

The URL List feature enables you to control access to customized URL lists (up to one million entries). The feature filters websites by applying a URL filtering policy bound to a virtual server.

As an administrator, you must import the URL List into the NetScaler appliance. This imported list is internally stored as a Policy data set called a *URL Set*. The appliance then applies a unique fast URL matching algorithm to the incoming URL requests. If the incoming URL request matches an entry in the set, the appliance applies the associated policy action to control access.

URL List Types

Each entry in a URL set can include a URL and, optionally, its metadata (URL category, category groups, or any other related data). For URLs with a metadata, the appliance uses a policy expression that evaluates the metadata. For more information, see URL Sets.

Custom URL List. You can create a customized URL set of up to 1,000,000 URL entries and import it as a text file into your appliance. The list can contain URLs with or without metadata

© 1997–2026 Citrix Systems, Inc. All rights reserved.

(which could be like a URL category). TheNetScaler platform automatically detects whether metadata is present. It also supports storing the imported lists securely. For more information, see URL Set.

You can host the URL list and configure the NetScaler appliance to periodically update the list without requiring manual intervention. Once the URL list is updated, the appliance can automatically detect the metadata and the categories by using policy expressions to evaluate each incoming URL and then apply actions such as allow, block, redirect, or notify the user.

URL List Policy Expressions

The following table describes the basic expressions you can use to evaluate incoming traffic. After you import an URL List to the appliance, it is called a *URL Set*.

EXPRESSION	OPERATION
`<URL expression>.URLSET_MATCHES_ANY(<URLSET>)`	Evaluates to TRUE if the URL exactly matches any entry in the URL set.
`<URL expression>.GET_URLSET_METADATA(<URLSET>)`	The GET_URLSET_METADATA() expression returns the associated metadata if the URL exactly matches any pattern within the URL set. An empty string is returned if there is no match.
`<URL expression>.GET_URLSET_METADATA(<URLSET>).EQ(<METADATA>)`	Evaluates to TRUE if the matched metadata is equal to `<METADATA>`.
`<URLexpression>.GET_URLSET_METADATA(<URLSET>).TYPECAST_LIST_T(‘,’).GET(0).EQ(<CATEGORY>)`	Evaluates to TRUE if the matched metadata is at the beginning of the category. This pattern can be used to encode separate fields within metadata, but match only the `1<sup>st</sup>` field.
HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL)	Joins the host and URL parameters, which can then be used as a `<URL expression>` for matching.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

URL List Policy Actions

The most common enforcement action for URLs that match a URL list is to restrict access. Create a URL list policy with a desired URL list matching expression and enforcement action. The policy group usage depends upon the incoming traffic type (HTTP or HTTPS) and the virtual server configured on the appliance. You can use a Responder policy for HTTP traffic or a Video Optimization policy for HTTPS traffic. Specify actions to apply to the URLs that match the expressions in the policies. The following table lists the available actions.

ACTION TYPE	POLICY	DESCRIPTION
ALLOW	Responder	Allow the request to access the target URL.
REDIRECT	Responder	Redirect the request to the URL specified as the target.
DENY	Responder	Deny the request.
RESET	Responder, VideoOptimization	Reset the connection.
DROP	Responder, VideoOptimization	Drop the connection.

Prerequisites

To configure URL List feature, make sure you have configured the following server.

DNS Server for DNS Requests

You must configure a DNS server if you import a URL Set from a hostname URL.

At the command prompt, type:

```
add dns nameServer ((<IP> [-local]) | <dnsVserverName>) [-state (ENABLED |
DISABLED )] [-type <type>] [-dnsProfileName <string>]
```

Example:

```
add dns nameServer 10.140.50.5
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Importing a custom URL list

To import a URL set, see URL Set topic.

Configuring a URL List for HTTP traffic

The NetScaler appliance supports HTTP and HTTPS traffic. To configure a load balancing virtual server for HTTP traffic and bind URL list policies to the server, do the following:

- Add URL List actions.
- Add URL List policies.
- Add an HTTP load balancing virtual server for HTTP traffic
- Bind the URL List policies to the HTTP load balancing virtual server for HTTP traffic

To add a URL list action

At the command prompt, type the following:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment
<string>] [-responseStatusCode <positive_integer>] [-reasonPhrase
<string>]
```

To add a HTTP load balancing virtual server for HTTP traffic

At the command prompt, type the following:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT imeout
<secs>]
```

Example:

```
add lb vserver vsrv-HTTP HTTP * 80 -persistenceType NONE -cltTimeout 120
```

To bind URL list policy to HTTP load balancing virtual server

At the command prompt, type the following:

```
bind lb vserver <vServerName> -policyName <string> [-priority
<positive_integer>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring URL List for HTTPS traffic

The NetScaler appliance supports HTTP and HTTPS traffic. To configure a SSL-bridge load balancing virtual server for HTTPS traffic and bind URL list policies to the server, do the following:

- Add URL List actions.
- Add URL List policies.
- Add a SSL-bridge load balancing virtual server for HTTP traffic
- Bind the URL List policies to the SSL-bridge load balancing virtual server for HTTP traffic

To add a URL List policy for HTTPS traffic

At the command prompt, type:

```
add videooptimization detectionpolicy <name> -rule <expression> -action
<string> [-undefAction <string>] [-comment <string>] [-logAction <string>]
```

To add a SSL-bridge load balancing virtual server

At the command prompt type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT imeout
<secs>]
```

Example:

```
add lb vserver vsrv-HTTPS SSL_BRIDGE * 443 -persistenceType NONE
-cltTimeout 180
```

To bind URL List policy with SSL-bridge load balancing by using the CLI

At the command prompt type:

```
bind lb vserver <vServerName> -policyName <string> [-priority
<positive_integer>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring a URL List by using the GUI

The GUI enables you to:

- Import a URL list.
- Add a URL list.
- Configure URL list actions.
- Configure URL list policies for HTTP traffic.
- Add an HTTP load balancing virtual server for HTTP traffic.
- Add an SSL-bridge load balancing virtual server for HTTPS traffic.
- Bind URL list policies to the HTTP load balancing virtual server.
- Bind a URL list policies to the SSL-bridge load balancing virtual server.

To import a URL list

1. In the navigation pane, expand **AppExpert** > **URL Sets**.
2. In the details pane, click **Import**.
3. On the **Configure URL Set** page, set the following parameters.
    a. **Name**. Name of the URL set.
    b. **URL**. Web address of the location at which to access the URL Set.
    c. **Overwrite**. Overwrite a previously imported URL set.
    d. **Delimiter**. Character sequence that delimits a CSV file record.
    e. **Row Separator**. Row separator used in the CSV file. A single character value is permitted for example "/n".
    f. **Interval**. Interval in seconds, rounded off to the nearest 15 minutes, at which the URL set is updated.
    g. **Private Set.** Option to prevent exporting the URL set
    h. **Canary URL**. Internal URL for testing whether the content of the URL set is to be kept confidential. The maximum length of the URL is 2047 characters
4. Click **Create**, and then **Close**.

To add a URL list

1. In the navigation pane, expand **AppExpert** > **URL Sets**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. In the details pane, click **Add**.
3. On the **Create URL Set** page, set the following parameters.
    a. **Name**. The name of the URL set that was given when it was imported.
    b. **Comments**. A short description about the URL set.
4. Click **Create**.

To configure a URL list action

1. Log on to the NetScaler appliance and navigate to **Configuration** tab page.
2. In the menu pane, navigate to **AppExpert** > **Responder** > **Actions**.
3. In the details pane, click **Add**.
4. On the **Create Responder Action** page, set the following parameters.
    a. **Name**. Name of the URL List policy action.
    b. **Type**. Select an action type.
    c. **Expression**. Use the expression editor to create the policy expression.
    d. **Comments**. A short description about the policy action.
5. Click **Create** and **Close**.

To configure a URL list policy

1. In the navigation pane, expand **AppExpert** > **Responder** > **Policies**.
2. In the details pane, click **Add**.
3. On the **Create Responder Policy** page, set the following parameters.
    a. **Name**. Name of the URL List policy action.
    b. **Action**. Select the URL List action that you prefer to associate with the policy.
    c. **Log Action**. Select the log action.
    d. **AppFlow®**. Select an AppFlow action.
    e. **Expression**. Use the expression editor to create the policy expression.
    f. **Comments**. A short description about the policy.
4. Click **Create** and **Close**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To add an HTTP load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:
    a. **Name**. Name of the load balancing virtual server.
    b. **Protocol**. Choose protocol type as HTTP.
    c. **IP Address Type**. IP addressable type.
    d. **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.
    e. **Port**. Port number of the virtual server.
4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see Creating a Virtual Server.

To bind a URL List policy to the HTTP load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.
    a. Choose Policy. Select a URL categorization policy from the drop-down list.
    b. Choose Type. Select the policy type as Request.
6. Click **Continue**.
7. In the Policies page, select the URL List policy from the list and click **Select**.
8. In the **Policies** slider, click **Bind** and **Close**.

To add URL List policy for HTTPS traffic

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Detection**.
2. On the **Detection** page, click the **Video Optimization Detection Policies** link.
3. On the **Video Optimization Detection Policies** page, click **Add**.
4. On the **Create Video Optimization Detection Policy** page, set the following parameters.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. **Name**. Name of the optimization policy
b. **Expression**. Configure policy using custom expressions.
c. **Action**. Optimization action associated with the policy to handle the incoming video traffic.
d. **UNDEF Action**. Undefined event if the incoming request does not match the optimization policy.
e. **Comment**. A short description of the policy.
f. **Log Action**. Select an audit log action that specifies the action to be performed for the log messages.

5. Click **Create** and **Close**.

To add a SSL-bridge load balancing virtual server for HTTPS traffic

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** screen, set the following parameters:

a. **Name**. Name of the load balancing virtual server.
b. **Protocol**. Select protocol type as SSL-bridge.
c. **IP Address Type**. IP address type: IPv4 or IPv6.
d. **IP Address**. IPv4 or IP6vIP address assigned to the virtual server.
e. **Port**. Port number of the virtual server.

4. Click **OK** to continue with the configuration of other, optional, parameters. For more information, see "Creating a Virtual Server" topic.

To bind a URL List Policy to the SSL-bridge load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. Set the following parameters.

a. **Choose Policy.** Select video detection policy from the drop-down list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

b. **Choose Type**. Select the policy type as Request.

6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

Configuring Audit Log Messaging

Audit logging enables you to review a condition or a situation in any phase of URL List process. When a NetScaler appliance receives an incoming URL, if the responder policy has an URL Set advanced policy expression, the audit log feature collects URL Set information in the URL and stores the details as a log message for any target allowed by audit logging.

The log message contains the following information:

1. Timestamp.
2. Log message type.
3. The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency).
4. Log message information, such as URL set name, policy action, URL.

To configure audit logging for URL List feature, you must complete the following tasks:

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging.

URL List Semantics

The following table lists the URL Match patterns and describes how the URLs within a URL list are matched against the incoming-request URLs. For example, the pattern `www.example.com/bar` matches only with one page at `www.example.com/bar`. To match all the pages whose URL starts with `www.example.com/bar`, you would add an asterisk (*) to the end of the URL.

SEMANTICS	URL PATTERN	MATCHED	UNMATCHED
Subdomain matching	domain.com	domain.com; `www.domain.com`; sub.one.domain.com	yourdomain.com; wwwdomain.com

© 1997–2026 Citrix Systems, Inc. All rights reserved.

SEMANTICS	URL PATTERN	MATCHED	UNMATCHED
URL matching, exact path	domain.com/example/bar/index.html	domain.com/example/bar/index.html; `www.domain.com/example/bar/index.html`; s.domain.com/example/bar/index.html	wwwdomaincom/example/bar/index.html; domain.com/example/bar/index.html/one.jpg
URL matching, exact path	domain.com/example/bar/index.html	domain.com/example/bar/index.html?key=value; `www.domain.com/example/bar/index.html?`; s.domain.com/example/bar/index.html	wwwdomaincom/example/bar/index.html; domain.com/example/bar/index.html/one.jpg
URL matching, subpath matching	domain.com/example/bar/	domain.com/example/bar/;domain.com/example/bar/index.html; `www.domain.com/example/bar/index.html`; domain.com/example/bar/index.html/one.jpg	wwwdomaincom/example/bar/index.html

URL Categorization

NOTE:

URL categorisation in the URL filtering feature is deprecated in this release.

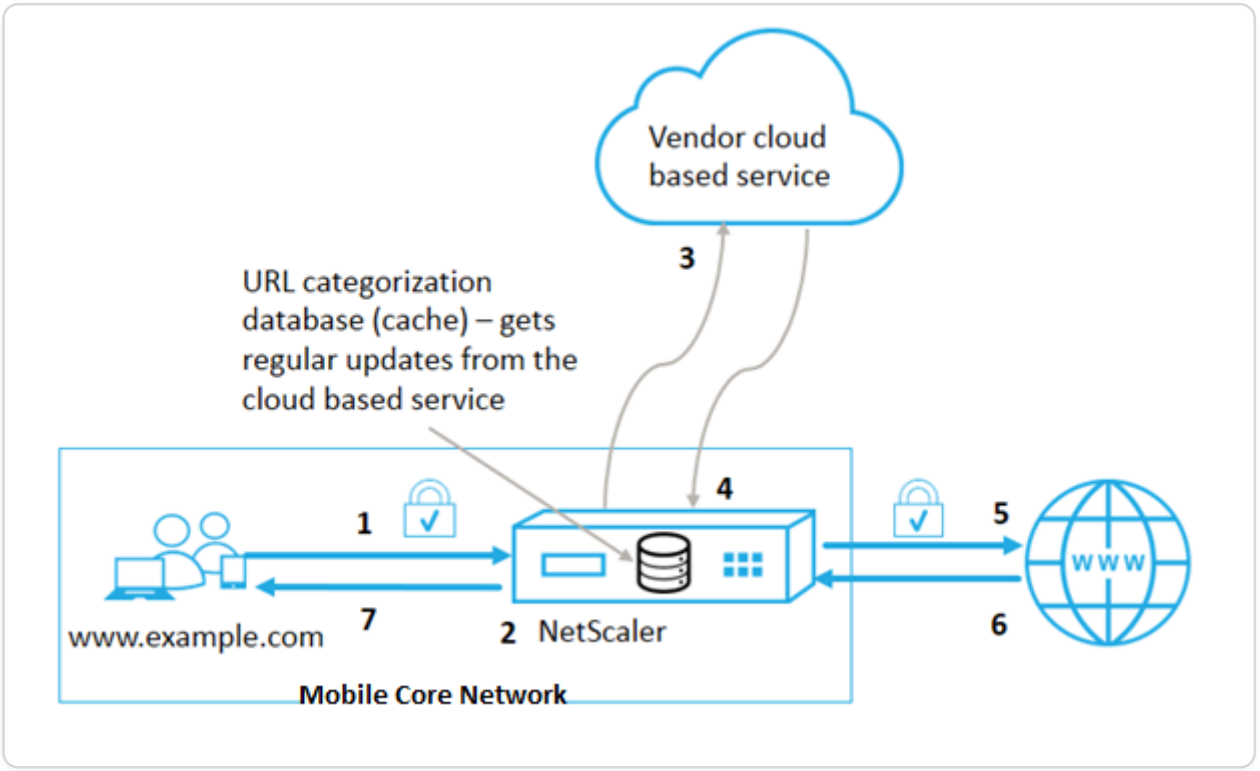
© 1997–2026 Citrix Systems, Inc. All rights reserved.

URL Categorization restricts user access to specific websites and website categories. As a subscribed service in collaboration with `NetSTAR`, the feature enables enterprise customers to filter web traffic using a commercial categorization database. The `NetSTAR` database has a vast number (billions) of URLs classified into different categories, such as social networking, gambling, adult content, new media, and shopping. In addition to categorization, each URL has a reputation score kept up to date based on the site's historical risk profile. We can use `NetSTAR` data to filter the traffic by configuring advanced policies based on categories, category groups (such as Terrorism, Illegal drugs), or site-reputation scores.

For example, you might block access to dangerous sites, such as sites infected with malware, or selectively restrict access to adult content or entertainment streaming media.

How URL Categorization Works

The following figure shows how the NetScaler URL Filtering service is integrated with a commercial URL Categorization database and cloud services for frequent updates.



The components interact as follows:

1. Client sends internet bound URL request.
2. A NetScaler policy attempts to evaluate the request in terms of categorization details (such as category, category group, and site-reputation score) retrieved from the URL categorization database. If the database returns the category details, the process jumps to step 5.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. If the database does not return categorization details, the request is sent to a cloud-based lookup service maintained by a URL categorization vendor. However, the appliance does not wait for a response. Instead, it marks the URL as Uncategorized and jumps to step 5. However, it continues to monitor the cloud query feedback and uses it to update the cache so that future requests can benefit from the cloud lookup.
4. The NetScaler appliance receives the URL category details (category, category group, and reputation score) from the cloud-based service and stores it in the cloud cache.
5. If the policy allows the URL, the request is sent to the origin server. Otherwise, the appliance drops or redirects the request, or responds with a custom HTML page.
6. The origin server responds with the requested data to the NetScaler appliance.
7. The appliance sends the response to the client.

You can use the URL filtering feature to detect sites that violate safe internet usage mandates issued by the government and implement policies to block these sites. Sites that host adult content, streaming media, or social networking identified as unsafe for children or banned as illegal.

Prerequisites

The feature works on Telco platforms with the purchase of a basic CBM license and CBM Premium license and for other NetScaler platforms, the feature works with the purchase of a CNS Premium license.

Note: In addition to a Basic CBM license and a CBM Premium license, the appliance must have a URL Threat Intelligence license with a subscription service for 1 year or 3 years. Before enabling and configuring the feature, you must install the following licenses:

License support for Telco platforms:

- **CBM_TXXX_SERVER_Retail.lic**
- **CBM_TPRE_SERVER_Retail.lic**
- **CNS_WEBF_SSERVER_Retail.lic**

Where XXX is the throughput, for example, NetScaler T1000.

License support for other NetScaler platforms:

- **CNS_XXX_SERVER_PLT_Retail.lic**

Where XXX is the throughput.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

URL Categorization Policy Expressions

The following table lists the different URL categorization policy expressions for identifying incoming URLs and applies a configured action.

EXPRESSION	OPERATION
`<text>. URL_CATEGORIZE (<min_reputation>, <max_reputation>)`	Returns a URL_CATEGORY object. Reputation score is a number from 1 to 4. To get objects all reputation scores use 0.0 as `<min reputation>` and <max_reputation>. If <min_reputation> is greater than 0, the returned object does not contain a category with reputation lower than <min_reputation>. If <max_reputation> is greater than 0, the returned object does not contain a category with reputation higher than <max_reputation>. If the category fails to resolve in a timely manner, the undef value is returned.
<url_category>. CATEGORY	Returns the category string for this object. If the URL does not have a category, or if the URL is malformed, the returned value is "Uncategorized".
<url_category>. GROUP	Returns a string identifying the object's category group. This is a higher level grouping of categories, which is useful in operations that require less detailed information about the URL category. If the URL does not have a category, or if the URL is malformed, the returned value is "Uncategorized".
<url_category>. REPUTATION	Returns the reputation score as a number from 1 to 4, where 4 indicates the riskiest reputation. If the category is "Uncategorized," the reputation value is 2.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Sample Policy Expressions

POLICY	POLICY EXPRESSIONS
Policy to select requests for URLs that are in the Search Engine category	add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ .URL).URL_CATEGORIZE(0,0). CATEGORY.EQ("Search Engine")
Policy to select requests for URLs that are in the Adult category group	add responder policy p1 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ .URL).URL_CATEGORIZE(0,0). GROUP.EQ("Adult")'
Policy to select requests for Search Engine URLs with a reputation score equal to 4.	add responder policy p2 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ .URL).URL_CATEGORIZE(4,0). CATEGORY.EQ("Search Engine")'
Policy to select requests for Search Engine and Shopping URLs	add policy patset good_categories; bind policy good_categories "Search Engine"; bind policy good_categories "Shopping"; add responder policy p3 'HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ .URL).URL_CATEGORIZE(0,0). CATEGORY .EQUALS_ANY("good_categories ")
Policy to select requests for Search Engine URLs with a reputation score equal to 4.	add responder policy p5 'CLIENT.SSL.DETECTED_DOMAIN.URL_CAT EGORIZE(4,0). CATEGORY.EQ("Search Engine")

URL Categorization Policy Actions

A URL filtering policy evaluates the traffic to identify requests belonging to a particular category. The following table lists the actions that you can assign to a URL filtering policy.

POLICY ACTION	POLICY GROUP	DESCRIPTION
ALLOW	Responder	Allow the incoming request to access the target URL

© 1997–2026 Citrix Systems, Inc. All rights reserved.

POLICY ACTION	POLICY GROUP	DESCRIPTION
REDIRECT	Responder	Redirect the incoming request to the URL specified as the target.
DENY	Responder	Deny incoming request.
RESET	Responder, VideoOptimization	Reset connection.
DROP	Responder, VideoOptimization	Drop connection.

NOTE

For encrypted traffic, the VideoOptimization policy includes actions that implement the URL Filtering actions.

Configuring URL Categorization

To configure URL categorization, begin by enabling the URL Filtering feature. You must then configure the cache memory limits, categorization policy, and virtual servers for HTTP and HTTPS traffic. Configuring URL Categorization by using the CLI.

To use the CLI configure URL categorization on a NetScaler appliance, do the following:

- Set up URL Categorization.
  - Enable the URL Filtering feature.
  - Configure shared memory to limit cache memory.
  - Configure URL categorization parameters.
- Configure URL categorization for HTTP traffic.
  - Add URL categorization actions.
  - Add URL categorization policies.
  - Add a load balancing virtual server for HTTP traffic.
  - Bind URL categorization policies to the load balancing virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Configure URL categorization for HTTPS traffic.
    - Add URL categorization policies.
    - Add a SSL-Bridge load balancing virtual server.
    - Bind URL categorization policies to the load balancing virtual server.

Setting up URL Categorization

To set up the feature, you must enable the URL Categorization feature, configure the filtering parameters and set the shared memory limit.

To enable URL Filtering feature

At the command prompt, type:

```
enable ns feature URLFiltering VideoOptimization Responder IC SSL AppFlow
```

To configure shared memory limit

At the command prompt, type:

```
set cache parameter [-memLimit <megaBytes>]
```

Where memLimit is the memory limit for caching.

Example:

```
set cache parameter -memLimit 10
```

To configure URL categorization parameters

At the command prompt, type:

```
set urlfiltering parameter [-HoursBetweenDBUpdates <positive_integer>] [-
TimeOfDayToUpdateDB <HH:MM>]
```

***Example:**

```
set urlfiltering parameter -HoursBetweenDBUpdates 3 -TimeOfDayToUpdateDB 03:00
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring URL categorization for HTTP traffic

To configure the URL categorization feature for HTTP traffic, you must configure a loading balancing virtual server, add URL categorization policies and bind the policies to the virtual server. By doing so, the virtual server receives the HTTP traffic and based on policy evaluation, the system assigns a filtering action.

To add URL categorization action for HTTP traffic

At the command prompt, type:

```
add responder action <name> <type> (<target> | <htmlpage>) [-comment <string>] [-responseStatusCode <positive_integer>] [-reasonPhrase <string>]
```

Example:

```
add responder action act_url_categorize respondwith "\"HTTP/1.1 200 OK\r\n\r\n\" + HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).CATEGORY + \"\n\""
```

To add URL categorization policy for HTTP traffic

At the command prompt, type:

```
add responder policy <name> <rule> <action> [<undefAction>] [-comment <string>] [-logAction <string>] [-appflowAction <string>]
```

Example:

```
add responder policy pol_url_categorize_http "HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).GROUP.EQ(\"Adult\") || HTTP.REQ.HOSTNAME.APPEND(HTTP.REQ.URL).URL_CATEGORIZE(0,0).GROUP.EQ(\"Gambling\")" RESET
```

To add an HTTP load balancing virtual server

If a virtual server for HTTP traffic is not already configured, at the command prompt, type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-clt Timeout <secs>]
```

Example:

```
add lb vserver vsrv-HTTP HTTP * 80 -persistenceType NONE -cltTimeout 120
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind URL categorization policy with load balancing virtual server

At the command prompt, type:

```
bind lb vserver <name> -policyName <string> [-priority <positive_integer>]
```

Example:

```
bind lb vserver vsrv-HTTP -policyName pol_url_categorize_http -priority 10
-gotoPriorityExpression END -type REQUEST
```

Configuring URL categorization for HTTPS traffic

To configure the URL categorization feature for HTTPS traffic, you must configure a SSL-bridge loading balancing virtual server, add URL categorization policies and bind the policies to the SSL-bridge virtual server. By doing so, the server receives the HTTPS traffic and based on policy evaluation, the system assigns a filtering action.

To add URL categorization policy for HTTPS traffic

At the command prompt, type:

```
add videooptimization detectionpolicy <name> -rule <expression> -action <string>
[-undefAction <string>] [-comment <string>] [-logAction <string>]
```

Example:

```
add videooptimization detectionpolicy pol_url_categorize_https_block_adult –rule
"CLIENT.SSL.DETECTED_DOMAIN.URL_CATEGORIZE(0,0).CATEGORY.EQ("Adult")' –action
RESET
```

To add SSL-Bridge load balancing virtual server

At the command prompt, type:

```
add lb vserver <name> [-td <positive_integer>] <serviceType> [-cltT imeout
<secs>]
```

Example:

```
add lb vserver vsrv-HTTPS SSL_BRIDGE * 443 -persistenceType NONE -cltTimeout
180
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind categorization policy with SSL-Bridge virtual server

At the command prompt, type:

```
bind lb vserver <name> -policyName <string> [-priority <positive_integer>]
```

Example:

```
bind lb vserver vsrv-HTTPS -policyName pol_url_categorize_https_block_adult
-priority 20 -type REQUEST
```

Configuring URL Categorization by using the GUI

The GUI enables you to:

- Enable the URL Categorization feature.
- Add URL Categorization actions for HTTP traffic.
- Add URL Categorization policies for HTTP traffic.
- Add URL Categorization policies for HTTPS traffic.
- Add a load balancing virtual server for HTTP traffic.
- Add an SSL bridge load balancing virtual server for HTTPS traffic.
- Bind URL Categorization policies to the load balancing virtual server.
- Bind URL Categorization policies to the SSL-Bridge load balancing virtual server.
- Configure shared memory limit.
- Configure URL categorization parameters.

To enable URL categorization

1. In the navigation pane, expand **System** and then click **Settings**.
2. On the **Settings** page, click **Configure Advanced Features** link.
3. On the **Configure Advanced Features** page, select **URL Filtering** check box.
4. Click **OK** and **Close**.

To add a URL categorization action

1. In the navigation pane, expand **AppExpert** > **Responder** > **Action**.
2. In the details pane, click **Add**.
3. On the **Create Responder Action** page, set the following parameters.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. **Name**. Name of the URL categorization policy action.

b. **Type**. Select an action type.

c. **Expression**. Use the expression editor to create the policy expression.

d. **Comments**. A short description of the policy action.

4. Click **Create** and **Close**.

To add a URL categorization policy for HTTP traffic

1. In the navigation pane, expand **AppExpert** > **Responder** > **Policies**.
2. On the details pane, click **Add**.
3. On the **Create Responder Policy** page, set the following parameters.

a. **Name**. Name of the URL categorization policy action.

b. **Action**. Select the URL Categorization action that you prefer to associate with the policy.

c. **Log Action**. Select the log action.

d. **AppFlow®**. Select an AppFlow action.

e. **Expression**. Use the expression editor to create the policy expression.

f. **Comments**. A short description about the policy action.

4. Click **Create** and **Close**.

To add a categorization policy for HTTPS traffic

1. Log on to the NetScaler appliance and navigate to **Configuration** > **Optimization** > **Video Optimization** > **Detection**.
2. On the **Detection** page, click the **Video Optimization Detection Policies** link.
3. On the Video Optimization Detection Policies page, click **Add**.
4. On the **Create Video Optimization Detection Policy** page, set the following parameters.

a. **Name**. Name of the optimization policy

b. **Expression**. Configure policy using custom expressions.

c. **Action**. Optimization action associated with the policy to handle the incoming video traffic.

d. **UNDEF Action**. Undefined event if the incoming request does not match the optimization policy.

e. **Comment**. A short description about the policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

f. **Log Action.** Select an audit log action that specifies the action to be performed for the log messages.

5. Click **Create** and **Close**.

To add a load balancing virtual server for HTTP traffic

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. In the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page set the following parameters:

   a. **Name**. Name of the load balancing virtual server.

   b. **Protocol**. Choose protocol type as HTTP.

   c. **IP Address Type.** IPv4 or IPv6.

   d. **IP Address.** IPv4 or IPv6, VIP address assigned to the virtual server.

   e. **Port**. Port number of the virtual server.

4. Click **OK** to continue with the configuration of other, optional, parameters.
5. Click **Create** and **Close**.

To add an SSL-bridge load balancing virtual server

1. Navigate to the **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. On the details pane, click **Add**.
3. On the **Load Balancing Virtual Server** page, set the following parameters:

   a. **Name**. Name of the load balancing virtual server.

   b. **Protocol**. Select protocol type as SSL-bridge.

   c. **IP Address Type**. IP addressable type.

   d. **IP Address**. IP 4 or IP6 IP address assigned to the virtual server.

   e. **Port**. Port number of the virtual server.

4. Choose **OK** to continue configuration other optional parameters.
5. Click **Create** and then **Close**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To bind a URL categorization policy to the HTTP load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** page.
2. On the details pane, select the load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click the **+** icon to access the **Policies** slider.
5. Set the following parameters.
    a. **Choose Policy**. Select URL categorization policy from the drop-down list.
    b. **Choose Type**. Select the policy type as Request.
6. Click **Continue**.
7. Select the URL categorization policy from the list and click **Close**.

To bind a categorization policy to the SSL-bridge load balancing virtual server

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers** screen.
2. In the details pane, select the SSL-bridge load balancing virtual server and click **Edit**.
3. In the **Advanced Setting** section, click **Policies**.
4. In the **Policies** section, click **+** icon to access the **Policies** slider.
5. In the **Policies** section, set the following parameters.
    a. **Choose Policy**. Select video detection policy from the drop-down list.
    b. **Choose Type**. Select the policy type as Request.
6. Click **Continue**.
7. Select the video detection policy from the list and click **Close**.

To configure the shared memory limit

1. Sign on to the appliance and navigate to **Optimization** > **Integrated Caching**.
2. In the details pane, click **Change cache settings** link.
3. On the **Cache Global Settings** page, set the following parameters.
    a. **Memory Usage Limit (MB).**
    b. **Active memory Usage Limit**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. **Via Header**.

d. **Maximum Post Body Length to be Cached**

e. **Global Undefined-Result Action**

f. **Enable HA Object Persist**

g. **Verify Cached Object Persist**

h. **Prefetches**

4. Click **OK** and **Close**.

To configure URL categorization parameters

1. Sign to the appliance and navigate to **Security**.
2. On the details pane, click **Change URL filtering settings** link.
3. In the **Configuring URL Filtering Params** page, set the following parameters.

   a. Hours Between DB Updates. URL Filtering hours between database updates. Minimum value: 0 and Maximum value: 720.

   b. Time of Day to Update DB. URL Filtering time of day to update the database.

4. Click **OK** and **Close.**

Configuring Audit Log Messaging

When a NetScaler appliance receives an incoming URL, if the responder policy has a URL Filtering expression, the audit log feature collects categorization information and displays it as log messages to any target audit log server that is configured. The info is logged.

- Source IP address (the IP address of the client that made the request).
- Destination IP address (the IP address of the requested server).
- Requested URL containing the schema, the host, and the domain name (`http://www.example.com`).
- URL category that the URL filtering framework returns.
- URL category group that the URL filtering framework returned.
- URL reputation number that the URL filtering framework returned.
- Audit log action taken by URL Categorization policy.

To configure audit logging for the URL List feature, you must complete the following tasks:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Enable Audit Log.
2. Create Audit Log message action.
3. Set URL List responder policy with Audit Log message action.

For more information, see Audit Logging topic.

Storing Failure Errors Using SYSLOG Messaging

At any stage of the URL Filtering process, if there is a system-level failure, the NetScaler appliance uses the audit log mechanism to store logs in the ns.log file. The errors are stored as text messages in SYSLOG format so that, an administrator can view it later in a chronological order of event occurrence. These logs are also sent to an external SYSLOG server for archival.

For example, if a failure occurs when you initialize the URL Filtering SDK, the error message is stored in the following messaging format.

Oct 3 15:43:40 `<local0.err>` ns URLFiltering: Error initializing NetStar SDK (SDK error=-1). (status=1).

The NetScaler appliance stores the error messages under four different failure categories:

- Download failure. If an error occurs when you try to download the categorization database.
- Integration failure. If an error occurs when you integrate an update into the existing categorization database.
- Initialization failure. If an error occurs when you initialize the URL Categorization feature, set categorization parameters, or end a categorization service.
- Retrieval failure. If an error occurs when the appliance retrieves the categorization details of the request.

URL Reputation Score

The URL Categorization feature provides policy-based control to restrict blacklisted URLs. You can control access to websites based on URL category, reputation score, or URL category and reputation score. If a network administrator monitors a user accessing highly risky websites, he or she can use a responder policy bound to the URL reputation score to block such risky websites.

Upon receiving an incoming URL request, the appliance retrieves the category and reputation score from the URL categorization database. Based on the reputation score returned by the database, the appliance assigns a reputation rating for websites. The value can range from 1 to 4, where 4 is the riskiest type of websites, as shown in the following table.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

URL REPUTATION RATING	REPUTATION COMMENT
1	Clean site.
2	Unknown site.
3	Potentially dangerous or affiliated to dangerous site.
4	Malicious site.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

FAQs

This section provides the FAQ on the following NetScaler features

- Authentication, Authorization, and Auditing
- Admin Partition
- AppFlow
- Call Home
- Clustering
- Connection Management
- Content Switching
- Debugging
- Hardware
- High Availability
- Integrated Caching
- Installing, Upgrading, and Downgrading
- Load Balancing
- NetScaler GUI
- SSL

Authentication, Authorization, and Auditing

Web Application Firewall protection

- Is it necessary to upgrade NetScaler to a version that addresses security vulnerabilities if the Web Application Firewall protection feature is enabled?

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Yes, because the Web Application Firewall protection feature does not resolve security vulnerabilities on NetScaler. It only offers protection against malicious attacks. We recommend you to always upgrade NetScaler to the latest version as it contains the latest security fixes.

- What are the licensing requirements for the Web Applciation Firewall feature?

  This feature is available with all the licenses (Standard, Enterprise, and Premium).

Admin Partition

Where can I get the NetScaler configuration file for a partition?

The configuration file (*ns.conf*) for the default partition is available in the */nsconfig* directory. For admin partitions, the file is available in the */nsconfig/partitions/\<partitionName>* directory.

How can I configure integrated caching in a partitioned NetScaler appliance?

NOTE

Integrated caching in admin partitions is supported from NetScaler 11.0 onwards.

To configure integrated caching (IC) on a partitioned NetScaler, after defining the IC memory on the default partition, the superuser can configure the IC memory on each admin partition such that the total IC memory allocated to all admin partitions does not exceed the IC memory defined on the default partition. The memory that is not configured for the admin partitions remains available for the default partition.

For example, if a NetScaler appliance with two admin partitions has 10 GB of IC memory allocated to the default partition, and the IC memory allocation for the two admin partitions is as follows:

- Partition1: 4 GB
- Partition2: 3 GB

Then, the default partition has 10 - (4 + 3) = 3 GB of IC memory available for use.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

If all IC memory is used by the admin partitions, no IC memory is available for the default partition.

What is the scope for L2 and L3 parameters in admin partitions?

NOTE

- Applicable from NetScaler 11.0 onwards.
- For ARP to work in non-default partition, you must enable the "proxyArp" parameter in the "set l2param" command.

On a partitioned NetScaler appliance, the scope of updating the L2 and L3 parameters is as follows:

- For L2 parameters that are set by using the "set L2Param" command, the following parameters can be updated only from the default partition, and their values are applicable to all the admin partitions:

  maxBridgeCollision, bdgSetting, garpOnVridIntf, garpReply, proxyArp, resetInterfaceOnHAfailover, and skip_proxying_bsd_traffic.

  The other L2 parameters can be updated in specific admin partitions, and their values are local to those partitions.
- For L3 parameters that are set by using the "set L3Param" command, all parameters can be updated in specific admin partitions, and their values are local to those partitions. Similarly, the values that are updated in the default partition are applicable only to the default partition.

How to enable dynamic routing in an admin partition?

NOTE

Dynamic routing in admin partitions is supported from NetScaler 11.0 onwards.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

While dynamic routing (OSPF, RIP, BGP, ISIS, BGP+) is by default enabled on the default partition, in an admin partition, it must be enabled by using the following command:

```
> set L3Param -dynamicRouting ENABLED
```

NOTE

A maximum of 63 partitions can run dynamic routing (62 admin partitions and 1 default partition).

On enabling dynamic routing on an admin partition, a virtual router (VR) is created.

- Each VR maintains its own vlan0 which will be displayed as vlan0_\<partition-name>.
- All unbound IP addresses that are exposed to ZebOS are bound to vlan0.
- The default VR (of the default partition) shows all the VRs that are configured.
- The default VR shows the VLANs that are bound to these VRs (except default VLANs).

Where can I find the logs for a partition?

NetScaler logs are not partition-specific. Log entries for all partitions must be stored in the */var/log/* directory.

How can I get audit logs for an admin partition?

In a partitioned NetScaler, you cannot have specific log servers for a specific partition. The servers that are defined at the default partition are applicable across all admin partitions. Therefore, to view the audit logs for a specific partition, you have to use the "show audit messages" command.

NOTE

The users of an admin partition do not have access to the shell and therefore are not able to access the log files.

How can I get web logs for an admin partition?

You can get the web logs for an admin partition as follows:

- **For NetScaler 11.0 and later versions**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The web logging feature must be enabled on each of the partitions that require web logging. Using the NetScaler Web Logging (NSWL) client, the NetScaler retrieves the web logs for all the partitions with which the user is associated.

- **For versions prior to NetScaler 11.0**

  Web logs can be obtained only by `nsroot` and other superusers. Also, even though web logging is enabled on the default partition, the NetScaler Web Logging (NSWL) client fetches web logs for all the partitions.

To view the partition for each log entry, customize the log format to include the %P option. You can then filter the logs to view the logs for a specific partition.

How can I get the trace for an admin partition?

You can get the trace for an admin partition as follows:

- **For NetScaler 11.0 and later versions**

  In a partitioned NetScaler appliance, the `nstrace` operation can be performed on individual admin partitions. The trace files are stored in the */var/partitions/\<partitionName>/nstrace/ *directory.

  Note: You cannot get the trace of an admin partition by using the GUI. You must use the CLI.

- **For versions prior to NetScaler 11.0**

  The `nstrace` operation can only be performed on the default partition. Therefore, packet captures are available for the entire NetScaler system. To get partition-specific packet captures, use VLAN-ID based filters.

How can I get the technical support bundle specific to an admin partition?

To get the tech support bundle for a specific partition, run the following command from the default partition:

```
> show techsupport -scope partition <partitionName>
```

Note: This command also gives system-specific information.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

AppFlow®

- **Which build of NetScaler supports AppFlow?**

  AppFlow is supported on NetScaler appliances running version 9.3 and above with nCore build.

- **What is the format used by AppFlow to transmit data?**

  AppFlow transmits information in the Internet Protocol Flow Information eXport (IPFIX) format, which is an open Internet Engineering Task Force (IETF) standard defined in RFC 5101. IPFIX (the standardized version of Cisco's NetFlow) is widely used to monitor network flow information.

- **What do AppFlow records contain?**

  AppFlow records contain standard NetFlow or IPFIX information, such as time stamps for the beginning and end of a flow, packet count, and byte count. AppFlow records also contain application-level information (such as HTTP URLs, HTTP request methods and response-status codes, server response time, and latency). IPFIX flow records are based on templates that must be sent before sending flow records.

- **After an upgrade to NetScaler Version 9.3 Build 48.6 Cl, why does an attempt to open a virtual server from the GUI result in the error message "The AppFlow feature is only available on NetScaler Ncore"?**

  AppFlow is supported only on nCore appliances. When you open the virtual server configuration tab, clear the **AppFlow** check box.

- **What does the transaction ID in an AppFlow records contain?**

  A transaction ID is an unsigned 32-bit number identifying an application-level transaction. For HTTP, a transaction corresponds to a request and response pair. All flow records that correspond to this request and response pair have the same transaction ID. A typical transaction has four flow records. If the NetScaler generates the response by itself (served from the integrated cache or by a security policy), there might be only two flow records for the transaction.

- **What is an AppFlow action ?**

  An AppFlow action is a set of collectors to which the flow records are sent if the associated AppFlow policy matches.

- **What commands can I run on the NetScaler appliance to verify that the AppFlow action is a hit?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The show AppFlow action. For example:

```
> show appflow action

1) Name: aFL-act-collector-1

  Collectors: collector-1

  Hits: 0

  Action Reference Count: 2

 2) Name: apfl-act-collector-2-and-3

  Collectors: collector-2, collecter-3

  Hits: 0

  Action Reference Count: 1

 3) Name: apfl-act-collector-1-and-3

  Collectors: collector-1, collecter-3

  Hits: 0

  Action Reference Count: 1
```

- **What is an AppFlow collector?**

A collector receives flow records generated by the NetScaler appliance. To be able to send flow records, you must specify at least one collector. You can specify up to four. You can remove unused collectors.

- **What NetScaler verison is required for using AppFlow?**

  Use NetScaler version 9.3.49.5 or higher, and remember that AppFlow is available in only the nCore builds.

- **What transport protocol does AppFlow use?**

  AppFlow uses UDP as the transport protocol.

- **What ports needs to be opened if I have a firewall in the network?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Port 4739. It is the default UDP port the AppFlow collector uses for listening on IPFIX messages. If the user changes the default port, that port must be opened on the firewall.

- **How can I change the default port AppFlow uses?**

  When you add an AppFlow collector by using the add appflowCollector command, you can specify the port to be used.

  ```
  > add appflowCollector coll1 -IPAddress 10.102.29.251 -port 8000

   Done
  ```

- **What does setting clientTrafficOnly do?**

  NetScaler generates AppFlow records only for client-side traffic.

- **How many collectors can be configured at a time?**

  You can configure up to four AppFlow collectors at a time on the NetScaler appliance. Note that the maximum number of collectors that can be configured on a NetScaler appliance is four.

Call Home

- **What is Call Home on a NetScaler appliance?**

  Call Home monitors, and notifies critical events on a NetScaler appliance. By enabling Call Home, you can automate the error notification process. You not only avoid calling NetScaler support, raise a service request, and upload system data before NetScaler support can troubleshoot the issue, but also identify and resolve issues before it occurs.

- **Is Call Home enabled by default on a NetScaler appliance?**

  Yes, Call Home is enabled by default on the appliance. If you upgrade to the latest software from an older version where Call Home was disabled by default, the upgrade process automatically enables the feature. If you later choose to disable it, the updated setting is remembered for all further upgrades. For information, see Call Home.

- **What are the pre-requisites for Call Home to work?**

  Access to an Internet connection.

  Note: If your NetScaler appliance does not have an Internet connectivity, you can configure a proxy server through which NetScaler can generate System Logs and upload it to the Citrix technical support server (CIS).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **What are the benefits of using Call Home?**
  - Monitor hardware and software error conditions.
  - Notify about the occurrence of critical events that impact your network.
  - Send performance data and System Logs to Citrix® to:
    - Analyze and improve product quality.
    - Provide real-time troubleshooting information for proactive issue identification, and faster issue resolution.
- **Which release of NetScaler software supports Call Home?**

  NetScaler release 10.0 and later.
- **What NetScaler platform models support Call Home?**

  Call Home feature is enabled by default on all NetScaler platforms and all appliance models (MPX, VPX, and SDX).
  - NetScaler MPX: All MPX models.
  - NetScaler VPX: All VPX models. In addition, it is supported on VPX appliances that obtain their licenses from external or central licensing pools. However, the feature remains the same as for a standard VPX appliance.
  - NetScaler SDX: Monitors the disk drive and assigned SSL chips for any errors or failures. The VPX instances, however, do not have access to the Power Supply Unit (PSU) and therefore their status is not monitored. In an SDX platform, you can configure Call Home either directly on an individual instance or through the SVM.
- **Should I configure SNMP alarm for Call Home to notify error conditions?**

  No, you need not configure SNMP for Call Home to monitor error conditions, because SNMP and Call Home uploads are independent of each other. If you want to be notified each time an error condition occurs, you can configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever a Call Home upload happens. The SNMP alert notifies the local administrator about the occurrences of critical events.
- **How do I contact a technical support?**

  For all critical hardware-related events, Call Home automatically creates a service request to NetScaler. For other errors, after you review the System Logs, you can contact the NetScaler

© 1997–2026 Citrix Systems, Inc. All rights reserved.

technical support team to open a service request for further investigation. To contact support, visit https://www.netscaler.com/resources/support.

- **What error conditions does Call Home monitor in a NetScaler appliance?**

  Call Home supports monitoring of the following events in a NetScaler appliance:

  - Compact flash drive errors
  - Hard disk drive errors
  - Power supply unit failure
  - SSL card failure
  - Warm restart
  - Memory anomalies
  - Rate limit drops

- **Do you need a separate license for Call Home?**

  No, Call Home does not require a separate license. You can enable it in all NetScaler platform licenses.

- **What data does Call Home send to NetScaler® support server and how frequently is it sent?**

  Call Home collects and sends two types of data to the CIS. They are:

  - Basic System information (running NetScaler version, deployment mode (standalone, HA, cluster), hardware details and so on). It is sent at the time of Call Home registration and as part of periodic heartbeats. The heartbeat is sent once every 30 days, but you can configure this interval anywhere from 1 to 30 days. However, a value of less than 5 days is not recommended, because frequent uploads are usually not very useful.
  - An abbreviated version of the `show tech support bundle` when there is an error condition. It is sent upon the first occurrence of a particular error condition since the appliance was last started. That is, a reoccurrence of the same error condition does not trigger another upload unless the appliance was rebooted after the previous occurrence.

- **Can Call Home generate and upload system logs through a proxy server?**

  Yes. If your NetScaler appliance does not have direct Internet connectivity, you can configure a proxy server and upload System Logs to the Citrix technical support server (CIS).

- **Can I review Call Home data before it is sent to CIS?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Unfortunately, you cannot review Call Home data before it is sent to CIS. Call Home does not collect any other data in addition to the data that you will provide when contacting the NetScaler support team.

- **How secure and private are the Call Home uploads?**

  Call Home provides data security and privacy in the following ways:

  - Uses a secure SSL/TLS channel to transfer data to Citrix servers.
  - Uploaded data is reviewed only by authorized personnel and is not shared with any third party.

Clustering

Click here for FAQs on clustering.

Connection Management

- **What is an admin connection?**

  An admin connection establishes a connection to the NSIP address and allows administrators to configure and monitor the NetScaler appliance.

- **What are the types of admin connections?**

  There are two types of admin connections:

  - SSH connection – Admin users use an SSH client to log on through the NSIP address.
  - NITRO API connection – Admin users use NITRO APIs to automate the logon process to the NetScaler appliance.

NOTE

Admin users can also log on through the GUI to log on, by using a browser to connect to the NSIP address. The GUI internally opens a NITRO API connection. Therefore, a GUI session is equivalent to a NITRO API connection, and FAQs related to the NITRO API apply to GUI.

- **How many concurrent admin connections are allowed on a NetScaler appliance?**

  The appliance allows up to 20 concurrent admin connections.

- **Which login credentials are required for an admin logon?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Admin logon requires a user name and a password.

Note: An authentication key can be used instead of a password.

- **Which external authentication methods does a NetScaler appliance support?**

  The appliance supports the following external authentication methods:

  - RADIUS
  - LDAP
  - TACACS

- **What is a client?**

  A client is a device (laptop or desktop), used by the admin user to open an admin connection.

- **What is a session token?**

  A session token is a unique identifier that the NetScaler appliance issues to a client that sends a NITRO API logon request.

  - API clients can reuse the session token, if it has not expired, for subsequent API requests on new TCP connections
  - GUI clients internally open NITRO API connections and keep the session token active during the GUI session.

- **What is an active session on a NetScaler appliance?**

  A CLI session is considered active if the session has not expired and has an open SSH connection with a NetScaler appliance.

  A NITRO API session is considered active if the session token timeout has not expired on the NetScaler appliance.

- **How does NetScaler enforce the concurrent connection limit?**

  Every time the NetScaler appliance receives an admin connection request (SSH or NITRO API), it checks the number of admin connections it has open. If the number is lower than 20, a new connection is opened.

- **Which counter reflects the number of admin connections on a NetScaler appliance?**

  The connection counter (nsconfigd_cur_clients) reflects the number of active connections. This counter is incremented when a client opens new connection to the appliance, and is decremented when a connection is closed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Which counter reflects the number of active tokens on the NetScaler appliance?**

  The *configd_cur_tokens* counter reflects the number of active tokens on the NetScaler appliance.

- **How does NetScaler appliance handle errors on a connection?**

  The NetScaler appliance immediately closes the client (CLI, API, and GUI) connection if it encounters errors on a connection.

- **Does a CLI or GUI session on a connection to the management address count against the admin connection limit?**

  Yes, all CLI and GUI connections are TCP based connections, and every TCP connection to the management address counts against the admin connection limit.

- **Does a NITRO session count against the admin connection limit?**

  A NITRO session counts against the admin connection limit if there is an open TCP connection using the session token issued by the NetScaler appliance.

- **What is the default timeout period for API, GUI, and CLI sessions on NetScaler appliance?**

  The following table lists the default timeout period for API, GUI, and CLI sessions on the NetScaler appliance:

NETSCALER RELEASES	CLI DEFAULT TIMEOUT PERIOD (MIN)	API DEFAULT TIMEOUT PERIOD (MIN)	GUI DEFAULT TIMEOUT PERIOD (MIN)
NetScaler 9.3	None	30 Minutes	30 Minutes
NetScaler 10.1	None	30 Minutes	30 Minutes
NetScaler 10.5 Onwards	15 Minutes	30 Minutes	15 Minutes

- **How can you set the CLI sessions time out on a NetScaler appliance?**

  The CLI session timeout can be configured by running the following command at the CLI prompt:

  ```
  set cli mode -timeout \<xx seconds>
  ```

- **How do you override the default timeout period when using the NITRO API?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

You can override the default timeout period for a NITRO API by setting the timeout duration in the "timeout" field of the login object. If the session timeout is set to zero, the session token has an infinite timeout.

Note: An infinite timeout is not advisable, because sessions that do not time out continue to count against the admin connection count.

- **What happens if a user account is deleted from the NetScaler appliance after an admin session is created?**

  For internal system users, the NetScaler appliance closes the existing CLI or NITRO API session.

  For external system users, the session remains active until it expires.

- **Can NITRO API clients use a single session token to open multiple admin connections on the NetScaler appliance?**

  Yes. Each such connection counts against the admin connection limit.

- **If management access is enabled for a SNIP address, do admin connections to that address count against the limit for the number of admin connections?**

  Yes, admin connections to management address (SNIP) count against the admin connection limit on NetScaler.

- **Can a NetScaler admin log on to the NetScaler appliance after the maximum connections limit is reached?**

  Yes. One more admin connection is allowed after the maximum connection limit is reached.

- **Can NITRO API endpoints open multiple admin connections on NetScaler the appliance?**

  Yes, NITRO API endpoints can open multiple admin connections and exhaust the concurrent admin connection limit on a NetScaler appliance. In such situations, an extra SSH/CLI connection is allowed and the admin can force closure of old API sessions, or reduce the session timeout duration for the existing API sessions.

- **Can same client open multiple API sessions on a NetScaler appliance?**

  Yes, a client can open multiple API sessions by repeatedly logging on. For example, the client might log back on after a reboot. Note: Repeated client logons count against the admin connection limit on NetScaler appliance.

- **Can API clients use the entire API session token limit?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Yes, API clients can use the entire API session token limit, provided by repeatedly logging on without using a previously issued token.

Note: If a client's session timeout is zero, the token is valid forever. Repeated logons using new session tokens can count against the limit for API session tokens.

- **Do CLI sessions count against the API session token limit?**

  No, CLI sessions are not counted against the API session token limit.

- **Can admin users use telnet to open a CLI session?**

  No. Only an SSH client can open a CLI session.

- **What is connection limit and API session limit applicable for various NetScaler releases?**

  The following table lists the maximum concurrent admin connection and active API session limits applicable for various NetScaler releases:

NETSCALER RELEASES	9.3	10.1 (BEFORE 130.X)	10.1 (BEFORE 130.10)	10.1 (FROM 130.10)
Maximum number of concurrent admin connections	20	20	20	20
Maximum number of active API sessions*	1000	20	1000	1000

  Note:

  - API sessions are considered active if they have not timed out. For example, if 500 API sessions were created but 100 have expired, 400 API sessions are active.
  - An API session need not open a TCP connection to the NetScaler appliance.

Content Switching

- **I have installed a non-NetScaler load balancing appliance on the network. However, I would like to use the content switching feature of the NetScaler appliance to direct the client requests to the load balancing appliance. Is it possible to use the Content**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

switching feature of the NetScaler appliance with a non-NetScaler load balancing appliance?

Yes. You can use the Content switching feature of the NetScaler appliance with the load balancing feature of the NetScaler appliance or a non-NetScaler load balancing appliance. However, when using the non-NetScaler load balancing appliance, make sure that you create a load balancing virtual server on the NetScaler appliance and bind it to the non-NetScaler load balancing appliance as a service.

- **How is a Content switching virtual server different from a load balancing virtual server?**

  A Content switching virtual server is capable only of sending the client requests to other virtual servers. It does not communicate with the servers.

  A Load balancing virtual server balances the client load among servers and communicates with the servers. It monitors server availability and can be used to apply different load balancing algorithms to distribute the traffic load.

  Content switching is a method used to direct client requests for specific types of content to targeted servers by way of load balancing virtual servers. You can direct the client requests to the servers best suited to handle them. This result in reduced overheads to process the client requests on the servers.

- **I want to implement the Content switching feature of the NetScaler appliance to direct the client requests. What types of client request can I direct by using the Content switching feature?**

  You can direct only HTTP, HTTPS, FTP, TCP, Secure TCP, and RTSP client requests by using the Content switching feature. To direct HTTPS client requests, you must configure the SSL offload feature on the appliance.

- **I want to create Content switching rules on the NetScaler appliance. What are the various elements of the client request on which I can create a content switching rule?**

  You can create the content switching rules based on the following elements and their values in the client request:

  - URL
  - URL tokens
  - HTTP version
  - HTTP Headers
  - Source IP address of the client

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Client version
- Destination TCP port

- **I understand that the content switching feature of the NetScaler appliance helps enhance the performance of the network. Is this correct?**

  Yes. You can direct the client requests you the servers best suited to handle them. The result is reduced overhead for processing the client requests on the servers.

- **Which feature of the NetScaler appliance should I configure on the NetScaler appliance to enhance the site manageability and response time to the client requests?**

  You can configure the content switching feature of the NetScaler appliance to enhance the site manageability and response time to the client request. This feature enables you to create content groups within the same domain name and IP address. This approach is flexible, unlike the common approach of explicitly partitioning the content into different domain names and IP addresses, which are visible to the user.

  Multiple partitions dividing a website into various domain names and IP addresses force the browser to create a separate connection for each domain it finds when rendering and fetching the content of a webpage. These additional WAN connections degrade the response time for the webpage.

- **I have hosted a web site on a web server farm. What advantages does the NetScaler content switching feature offer for this type of setup?**

  The content switching feature provides the following advantages on a NetScaler appliance in a site that is based in a web server farm:

  - Manage the site content by creating a content group within the same domain and IP address.
  - Enhance the response time to client requests by using the content group within the same domain and IP address.
  - Avoid the need for full content replication across domains.
  - Enable application-specific content partitioning. For example, you can direct client requests to a server that handles only dynamic content or only static content, as appropriate for the request.
  - Support multi-homing of multiple domains on the same server and use the same IP address.
  - Reuse connections to the servers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **I want to implement the content switching feature on the NetScaler appliance. I want to direct the client requests to the various servers after evaluating the various parameters of each request. What approach should I follow to implement this setup when configuring the content switching feature?**

  You can use policy expressions to create policies for the content switching feature. An expression is a condition evaluated by comparing the qualifiers of the client request to an operand by using an operator. You can use the following parameters of the client request to create an expression:

  - **Method**- HTTP request method.
  - **URL**- URL in the HTTP header.
  - **URL TOKENS**- Special tokens in the URL.
  - **VERSION**- HTTP request version.
  - **URL QUERY**- Contains the URL Query LEN, URL LEN, and HTTP header.
  - **SOURCEIP**- IP address of the client.

  Following is a complete list of the operators that you can use to create an expression:

  - \== (equals)
  - \!= (not equals)
  - EXISTS
  - NOT EXISTS
  - CONTAINS
  - NOT CONTAINS
  - GT (greater than)
  - LT (less than)

  You can also create various rules, which are logical aggregations of a set of expressions. You can combine multiple expressions to create rules. To combine expressions, you can use the && (AND) and || (OR) operators. You can also use parenthesis to create nested and complex rules.

- **I want to configure a rule based policy along with a URL based policy for the same content switching virtual server. Is it possible to create both types of policies for the same content switching virtual server?**

  Yes. You can create both type of policies for the same content switching virtual server. However, be sure to assign priorities to set an appropriate precedence for the policies.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **I want to create content switching policies that evaluate the domain name, along with a prefix and suffix of a URL, and direct the client requests accordingly. Which type of content switching policy should I create?**

  You can create a Domain and Exact URL policy. When this type of policy is evaluated, the NetScaler appliance selects a content group if the complete domain name and the URL in the client request match the ones configured. The client request must match the configured domain name and exactly match the prefix and suffix of the URL if they are configured.

- **I want to create content switching policies that evaluate the domain name, along with a partial prefix and suffix of URL, and direct the client requests accordingly. Which type of content switching policy should I create?**

  You can create a Domain and Wildcard URL policy for the content switching virtual server. When this type of policy is evaluated, the NetScaler appliance selects a content group if the request matches the complete domain name and partially matches the URL prefix.

- **What is a Wildcard URL policy?**

  You can use wildcards to evaluate partial URLs in client requests to the URL you have configured on the NetScaler appliance. You can use wildcards in the following types of URL-based policies:

  - Prefix only. For example, the /sports/* expression matches all URLs available under the /sports URL. Similarly, the /sports* expression matches all URLs whose prefix is /sports.
  - Suffix only. For example the /*.jsp expression matches all URLs with a file name extension of jsp.
  - Prefix and Suffix. For example, the /sports/*.jsp expression matches all URLs under the /sports/ URL that also have the jsp file name extension. Similarly, the /sports*.jsp expression matches all URLs with a prefix of /sports* and a file name extension of jsp.

- **What is a Domain and Rule policy?**

  When you create a Domain and Rule policy, the client request must match the complete domain and the rule configured on the NetScaler appliance.

- **What is the default precedence set for evaluating policies?**

  By default, the rule based policies are evaluated first.

- **If some of the content is the same for all client requests, what type of precedence should I use for evaluating policies?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If some of the content is the same for all the users and different content must be served on the basis of client attributes, you can use URL-based precedence for policy evaluation.

- **What policy expression syntaxes are supported in content switching?**

  Content switching supports two types of policy expressions:

  - **Classic Syntax-** Classic syntax in content switching starts with the keyword REQ and is more advanced than the Advanced policy. Classic policies cannot be bound to an action. Therefore, the target load balancing virtual server can be added only after binding the content switching virtual server.
  - **Advanced policy:** Advanced policy generally starts with the key word HTTP and is easier to configure. A target load balancing virtual server action can be bound to a Advanced policy, and the policy can be used on multiple content switching virtual servers.

- **Can I bind a single content switching policy to multiple virtual servers?**

  Yes. You can bind a single content switching policy to multiple virtual servers by using policies with defined actions. Content switching policies that use an action can be bound to multiple content switching virtual servers because the target load balancing virtual server is no longer specified in the content switching policy. The ability to bind a single policy to multiple content switching virtual servers helps to further reduce the size of the content switching configuration.

  For more information, see the following Knowledge Center articles and NetScaler® documentation topics:

  - See CTX122918 - How to Bind the Same Content Switching Policy to Two Content Switching virtual server on a NetScaler Appliance.
  - See CTX122736 - How to Bind the Same Advanced Policy to Multiple Content Switching Virtual Servers using Policy Labels.
  - Configuring Basic Content Switching.

- **Can I create an action based policy using classic expressions?**

  No. As of now NetScaler does not support policies using classic syntax expressions with actions. The target load balancing virtual server must be added when binding the policy instead of defining it in an action.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Debugging

- **How can I determine the interface (CLI, GUI, or API) through which an operation was performed?**

  The NetScaler keeps track of the interfaces through which operations are performed. You can view this information in syslogs (in the GUI, navigate to Configuration > System > Auditing > Audit Messages > Syslog messages) or in the ns.log (located at the /var/log/ directory) file.

  For example, operations that are performed through the API are flagged as "API CMD_EXECUTED."

Hardware

Click here for FAQs about MPX hardware.

High Availability

Click here for FAQs about High Availability.

Integrated Caching

Content Groups

- **How is a DEFAULT content group different from other content groups?**

  The behavior of the DEFAULT content group is the same as any other group. The only attribute that makes the DEFAULT content group special is that if an object is being cached and no content group has been created. The object is cached in the DEFAULT group.

- **What is the 'cache-Control' option of the content group level?**

  You can send any cache-control header the browser. There is a content group level option, -cacheControl, which enables you to specify the cache-control header that you want to be inserted in the response to the browser.

- **What is the 'Minhit' option in content group level?**

  `Minhit` is an integer value specifying the minimum number of select to a cache policy before the object is cached. This value is configurable at the content group level. Following is the syntax to configure this value from the CLI.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add/set cache contentGroup \<Content_Group_Name> [-minHits \<Integer>]
```

- **What is the use of the expireAtLastByte option?**

  The expireAtLastByte option enables the integrated cache to expire the object when it is downloaded. Only requests that are outstanding requests then are served from the cache. any new requests are sent to the server. This setting is useful when the object is frequently modified, as in the case of stock quotes. This expiry mechanism works along with the Flash Cache feature. To configure a expireAtLastByte option, run the following command from the CLI:

  ```
  add cache contentGroup \<Group_Name> –expireAtLastByte YES
  ```

Cache policy

- **What is a caching policy?**

  Policies determine which transactions are cacheable and which are not. Also, policies add or override the standard HTTP caching behavior. Policies determine an action, such as CACHE or NOCACHE, depending on the specific characteristics of the request or response. If a response matches the policy rules, the object in the response is added to the content group configured in the policy. If you have not configured a content group, the object is added to the DEFAULT content group.

- **What is a policy hit?**

  A select occurs when a request or response matches a cache policy.

- **What is a miss?**

  A miss occurs when a request or response does not match any cache policy. A miss can also occur if the request or response matches a cache policy but some override of RFC behavior prevents the object from being stored in the cache.

- **I have configured Integrated Caching feature of the NetScaler appliance. When adding the following policy, an error message appears. Is there any error in the command?**

  ```
  add cache policy image_caching -rule exp1 | ns_ext_not_jpeg –action cache
  ```

  ```
  \> ERROR: No such command
  ```

  In the preceding command, the expression must be within the quotation marks. Without quotation marks, the operator is considered to be the pipe operator.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Memory Requirements

- **What are the commands that I can run on the NetScaler appliance to check the memory allocated to cache?**

  To display the memory allocated for cache in the NetScaler appliance, run any of the following commands from the CLI:

  - `show cache parameter`

    In the output, check the value of the Memory usage limit parameter. This is the maximum memory allocated for cache.

  - `show cache \<Content_Group_Name>`

    In the output, check the values of the Memory usage and Memory usage limit parameters indicating the memory used and allocated for the individual content group.

- **My NetScaler appliance has 2 GB of memory. Is there any recommended memory limit for cache?**

  For any model of the NetScaler appliance, you can allocate half of the memory to the cache. However, Citrix recommends allocating a little less than half of the memory, because of internal memory dependency. You can run the following command to allocate 1 GB of memory to the cache:

  `set cache parameter -memLimit 1024`

- **Is it possible to allocate memory for individual content groups?**

  Yes. Even though you allocate memory for the integrated cache globally by running the set cache parameter –memlimit\<Integer>, you can allocate memory to individual content groups by running the set cache \<Content_Group_Name> –memLimit \<Integer> command. The maximum memory you can allocate to content groups (combined) cannot exceed the memory you have allocated to the integrated cache.

- **What is the dependency of memory between integrated cache and TCP buffer?**

  If the NetScaler appliance has 2 GB memory, then the appliance reserves approximately 800 MB to 900 MB of memory and the remaining is allocated to the FreeBSD operating system. Therefore, you can allocate up to 512 MB of memory to the integrated cache and the rest is allocated to the TCP buffer.

- **Does it affect the caching process if I do not allocate global memory to the integrated cache?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you do not allocate memory to the integrated cache, all requests are sent to the server. To make sure that you have allocated memory to the integrated cache, run the show cache parameter command. Actually no objects are cached if the global memory is 0, so it must be set first.

Verification commands

- **What are the options for displaying cache statistics?**

  You can use either of the following options to display the statistics for cache:

  - `stat cache`

    To display the summary of the cache statistics.

  - `stat cache –detail`

    To display the full details of the cache statistics.

- **What are the options for displaying the cached content?**

  To display the cached content, you can run the `show cache object` command.

- **What is the command that I can run to display the characteristics of an object stored in cache?**

  If the object stored in the cache is, for example, GET //10.102.12.16:80/index.html, you can display the details about the object by running the following command from the CLI of the appliance:

  `show cache object -url '/index.html' -host 10.102.3.96 -port 80`

- **Is it mandatory to specify the group name as a parameter to display the parameterized objects in cache?**

  Yes. It is mandatory to specify the group name as a parameter to display the parameterized objects in the cache. For example, consider that you have added the following policies with the same rule:

  ```
  add cache policy p2 -rule ns_url_path_cgibin -action CACHE –
  storeInGroup g1
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add cache policy p1 -rule ns_url_path_cgibin -action CACHE
-storeInGroup g2
```

In this case, for the multiple requests, if policy p1 is evaluated, its select counter is incremented and the policy stores the object in the g1 group, which has select parameters. Therefore, you have to run the following command to display the objects from the cache:

`show cache object -url "/cgi-bin/setCookie.pl" -host 10.102.18.152 groupName g1`

Similarly, for another set of multiple requests, if policy p2 is evaluated, its select counter is incremented and the policy stores the object in the g2 group, which does not have select parameters. Therefore, you have to run the following command to display the objects from the cache:

`show cache object -url "/cgi-bin/setCookie2.pl" -host 10.102.18.152`

- **I notice that there are some blank entries in the output of the nscachemgr command. What are those entries?**

  Consider the following sample output of the `nscachemgr` command. The blank entries in this output are highlighted in bold face for your reference:

```
root@ns# /netscaler/nscachemgr -a

//10.102.3.89:80/image8.gif

//10.102.3.97:80/staticdynamic.html

//10.102.3.97:80/

//10.102.3.89:80/image1.gif

//10.102.3.89:80/file5.html

//10.102.3.96:80/

//10.102.3.97:80/bg_logo_segue.gif

//10.102.3.89:80/file500.html

//10.102.3.92:80/
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
//10.102.3.96:80/cgi-bin/rfc/ccProxyReval.pl

Total URLs in IC = 10
```

The blank entries in the output are due to the default caching properties for GET / HTTP/1.1.

Flushing Objects

- **How can I flush a selective object from the cache?**

  You can identify an object uniquely by its complete URL. To flush such an object, you can perform any of the following tasks:

  - Flush cache
  - Flush content group
  - Flush the specific object

  To flush the specific object, you have to specify the query parameters. You specify the invalParam parameter to flush the object. This parameter applies only to a query.

- **Does any change in the cache configuration trigger flushing of cache?**

  Yes. When you change to the cache configuration, all the SET cache commands inherently flush the appropriate content groups.

- **I have updated the objects on the server. Do I need to flush the cached objects?**

  Yes. When you update objects on the server, you must flush the cached objects, or at least the relevant objects and content groups. The integrated cache is not affected by an update to the server. It continues to serve the cached objects until they expire.

Flash Cache

- **What is Flash Cache feature of the NetScaler appliance?**

  The phenomenon of Flash crowds occurs when many clients access the same content. The result is a sudden surge in traffic toward the server. The Flash Cache feature enables the NetScaler appliance to improve performance in such a situation by sending only one request to the server. All other requests are queued on the appliance and the single response is served to the requests. You can use either of the following commands to enable the Fast Cache feature:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `add cache contentGroup \<Group_Name> -flashCache YES`
- `set cache contentGroup \<Group_Name> -flashCache YES`

- **What is the limit for Flash Cache clients?**

  The number of Flash Cache clients depends on the availability of resources on the NetScaler appliance.

Default Behavior

- **Does the NetScaler appliance proactively receive objects upon expiry?**

  The NetScaler appliance never proactively receives objects on expiry. This is true even for the negative objects. The first access after expiry triggers a request to the server.

- **Does the integrated cache add clients to the queue for serving even before it starts receiving the response?**

  Yes. The integrated cache adds clients to the queue for serving even before it starts receiving the response.

- **What is the default value for the Verify cached object using parameter of the cache configuration?**

  HOSTNAME_AND_IP is the default value.

- **Does the NetScaler appliance create log entries in the log files?**

  Yes. The NetScaler appliance creates log entries in the log files.

- **Are compressed objects stored in the cache?**

  Yes. Compressed objects are stored in the cache.

Interoperability with other features

- **What happens to objects that are currently stored in cache and are being accessed through SSL VPN?**

  Objects stored in the cache and accessed regularly are served as cache, select when accessed through the SSL VPN.

- **What happens to objects stored in the cache when accessed through SSL VPN and later accessed through a regular connection?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The objects stored through the SSL VPN access are served as a select when accessed through the regular connection.

- **When using web logging, how do I differentiate entries that indicate response served from cache from those served by the server?**

  For responses served from the integrated cache, the server log field contains the value IC. For responses served from a server, the server log field contains the value sent by the server. Following is a sample log entry for an integrated caching transaction:

  ```
  "10.102.1.52 - "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 4.0; .NET CLR 1.0.3705)" "GET /" 200 0 "IC" 10.102.1.45"
  ```

  Along with a client request, the response logged is the one sent to the client and not necessarily the one sent by the server.

NOTE

When using the web logging, the responses from the integrated cache contains the value IC in the server log field. The server log field is present in the NSWL client with “%o1” format specifier.

Miscellaneous

- **What do you mean by configuring relexpiry and absexpiry?**

  By configuring `relexpiry` and `absexpiry`, it means that you are overriding the header irrespective of what appears in the header. You can configure a different expiry setting and the content group level. With `relexpiry`, the expiration of the header is based on the time at which the object is received by the NetScaler. With `absexpiry`, expiration is based on the time configured on the NetScaler. `Relexpiry` is configured in terms of seconds. `Absexpiry` is a time of day.

- **What do you mean by configuring weakpos and heuristic?**

  The `weakpos` and heuristic are like fallback values. If there is an expiry header, it is considered only if the last-modified header is present. The NetScaler appliance sets expiry based on the last-modified header and the heuristic parameter. The heuristic expiry calculation determines the time to expiry by checking the last-modified header. Some percentage of the duration since the object was last modified is used as time to expiry. The heuristic of an object that remains unmodified for longer periods of time and is likely to have longer expiry periods.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The –heurExpiryParam specifies what percentage value to use in this calculation. Otherwise, the appliance uses the `weakpos` value.

- **What should I consider before configuring dynamic caching?**

  If there is some parameter that is in name-value form and does not have the full URL query, or the appliance receives the parameter in a cookie header or POST body, consider configuring dynamic caching. To configure dynamic caching, you have to configure the hitParams parameter.

- **How is hexadecimal encoding supported in the parameter names?**

  On the NetScaler appliance, the %HEXHEX encoding is supported in the parameter names. In the names that you specify for hitParams or invalParams, you can specify a name that contains %HEXHEX encoding in the names. For example, name, name%65, and n %61m%65 are equivalent.

- **What is the process for selecting a hitParam parameter?**

  Consider the following excerpt of an HTTP header for a POST request:

```
POST /data2html.asp?param1=value1&param2=&param3&param4=value4

HTTP/1.1

Accept: image/gif, image/x-xbitmap, image/jpeg, image/pjpeg,

application/vnd.ms-powerpoint, application/vnd.ms-excel,

application/msword, application/x-shockwave-flash, */*

Referer: http://10.102.3.97/forms.html

Accept-Language: en-us

Content-Type: application/x-www-form-urlencoded

Accept-Encoding: gzip, deflate

User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1)

Host: 10.102.3.97

Content-Length: 153
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Connection: Keep-Alive

Cache-Control: no-cache

Cookie: ASPSESSIONIDQGQGGRNY=NNLLKDADEENOAFLCCDGFGDMO

S1=This+text+is+only+text%2C+not+more+and+not+less%2C+
%0D%0Ajust+text+to+be+itself%2C+namely+%22Text%22+to+be+posted+as+text+
%28what+else...%29&B1=Submit
```

In the preceding request, you can use S1 and B1, highlighted in bold face for your reference, as hitParams depending on your requirements. Also, if you use -matchCookies YES in the ASPSESSIONIDQGQGGRNY content group, then you can also use these parameters as hitParams.

- **What happens to the queued clients if the response is not cacheable?**

  If the response is not cacheable, all the clients in the queue receive the same response that the first client receives.

- **Can I enable the Poll every time (PET) and Flash Cache features on the same content group?**

  No. You cannot enable PET and Flash Cache on the same content group. The integrated cache does not perform the AutoPET function on Flash Cache content groups. The PET feature ensures that the integrated cache does not serve a stored object without consulting the server. You can configure PET explicitly for a content group.

- **When are the log entries created for the queued clients?**

  The log entries are created for the queued clients soon after the appliance receives the response header. The log entries are created only if the response header does not make the object non-cacheable.

- **What is the meaning of the DNS, HOSTNAME, and HOSTNAME_AND_IP values of the Verify cached object using parameter of the cache configuration?**

  The meanings are as follows:

  - `set cache parameter -verifyUsing HOSTNAME`

    The command ignores the destination IP address.

  - `set cache parameter -verifyUsing HOSTNAME_AND_IP`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The command matches the destination IP address.

- `set cache parameter -verifyUsing DNS`

  The command uses the DNS server.

- **I have set weakNegRelExpiry to 600, which is 10 minutes. I noticed that 404 responses are not getting cached. What is the reason?**

  This completely depends on your configuration. By default, 404 responses are cached for 10 minutes. If you want all 404 responses to be fetched from the server, specify–weakNegRelExpiry 0. You can fine-tune the –weakNegRelExpiry to a desired value, such as higher or lower to get the 404 responses cached appropriately. If you have configured –absExpiry for positive responses, then it might not yield the desired results.

- **When the user accesses the site by using the Mozilla Firefox browser, the updated content is served. However, when the user accesses the site by using the Microsoft Internet Explorer browser, stale content is served. What could be the reason?**

  The Microsoft Internet Explorer browser might be taking the content from its local cache instead of the NetScaler integrated cache. The reason can be that the Microsoft Internet Explorer browser is not respecting the expiry related header in the response.

  To resolve this issue, you can disable the local cache of the Internet Explorer and clear the offline content. After clearing the offline content, the browser must display the updated content.

- **What if Hits are zero?**

  Check to see if the server time and NS time are in sync. And the weakPosrelexpiry limit set must bear the time difference between NS and server as following:

  ```
  root@ns180\# date

  Tue May 15 18:53:52 IST 2012
  ```

- **Why are policies getting hits but nothing is being cached?**

  Verify that memory is allocated to the integrated cache and that the allocation is greater than zero.

- **Is it possible to zero the cache counters?**

  There is no command line or GUI option for setting the cache counters to zero, and flushing the cache does not do so either. Rebooting the box automatically sets these counters to zero.

Install, upgrade, and downgrade

Install and upgrade

How to download a specific NetScaler release build package?

For information on downloading a specific NetScaler release build package, see Download a NetScaler release package.

How to upgrade the system software of a NetScaler appliance?

For information on upgrading the system software of a NetScaler appliance, see Upgrade a NetScaler standalone appliance.

Where do I find the release notes for a NetScaler release build?

The release notes document for a NetScaler release build lists the following for the release build:

- Enhancements
- Fixed issues
- Known issues

The release notes document for a NetScaler release build is found at the following locations:

- NetScaler firmware or virtual appliance downloads page of a specific release build.
- ADC release notes page in NetScaler docs site

Where do I find security updates for NetScaler appliances?

NetScaler security team regularly releases security bulletins on Common Vulnerabilities and Exposures (CVE) for all related NetScaler products. This information can be found at security bulletin. Alternatively, you can search for a specific CVE at NetScaler support site.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

What is the use of the zebos.conf file available in a NetScaler release?

A NetScaler appliance uses ZebOS as the routing suite. The zebos.conf file available in a NetScaler release is the configuration file for ZebOS.

I want to change the SSH port (22) on the NetScaler appliance to some other port. Is it possible to change the SSH port on the appliance?

Yes. You can change the SSH port on the NetScaler appliance by editing the sshd_config file in the "/nsconfig" directory. If the file does not exist in the /nsconfig directory, copy it from the "/etc" directory.

In the sshd_config file, edit the entry for Port 22 to Port \<Number>, where \<Number> is the target port number. If you do not want to restart the appliance and make the changes effective, terminate the `sshd` process by using the kill command, and then restart the process.

NOTE:

Some features such as config synchronization, file synchronization, and HA synchronization don't work after you customize the default SSH port.

The flash directory is missing from the NetScaler appliance. What procedure must I follow to mount the flash directory?

To mount the flash directory, do the following:

1. Start the NetScaler appliance in single-user mode.

   When the appliance starts, the following message appears:

   Select to boot immediately, or any other key for the command prompt. Booting in 10 seconds...” Select space and you must see the following prompt:

   Type '?' for a list of commands, 'help' for more detailed help.
2. Enter the following command to start FreeBSD in single-user mode:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

boot –s

After the appliance starts, the following message appears:

Enter full pathname of shell or RETURN for /bin/sh:

3. Press Enter to display the # prompt.
4. Run the following command to mount the flash directory:

```
mount /dev/ad0s1a /flash

Note: If the preceding command displays an error message about
permissions, run the following command to check the disk for
consistency:

fsck /dev/ad0s1a

Run the mount command again to mount the flash directory.
```

5. Restart the appliance.
6. From the shell prompt, run the following command to verify that the flash directory is mounted:

```
df -kh
```

I want to log on to the NetScaler appliance without entering the password. Is it possible to configure SSH on the appliance to allow that?

Yes. You can configure SSH on the NetScaler appliance to log on without a password. However, you must provide your user name. To configure SSH for logging in without a password, do the following:

1. Run the following command to generate the public and private keys:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
&num; ssh-keygen -t rsa
```

2. Run the following command to copy the id_rsa.pub file to the .ssh directory of the remote host that you want to log on to:

```
&num; scp id_dsa.pub \&lt;user>@\&lt;remote_host>/.ssh/id_dsa.pub
```

3. Log on to the remote host.
4. Change to the .ssh directory.
5. Run the following commands to add the public key of the client to the known public keys:

```
&num; cat id_dsa.pub >> authorized_keys2

&num; chmod 640 authorized_keys2

&num; rm id_dsa.pub
```

What is the procedure to reset the NetScaler appliance BIOS? Under what circumstances must I reset the BIOS?

To reset the BIOS of the NetScaler appliance, complete the following procedure:

1. Connect to the appliance through the serial port.
2. Start the appliance and press Delete when the boot-up process starts.

   Pressing Delete during the POST process displays the appliance's BIOS settings.
3. Activate the Exit page of the BIOS settings.
4. Select the Load Optimal Defaults option. The Load Optimal Settings message box appears.
5. Select OK.
6. Make the following changes to the BIOS settings on the various tabs:

   Tab
7. Activate the Exit page of the BIOS settings.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

8. Select Save changes and Exit.
9. Select OK to confirm.
10. Verify that the appliance starts cleanly and the serial console displays output after the appliance starts.

    You must reset BIOS when the serial console does not respond. This usually happens after you upgrade the appliance and the serial console is disabled. However, you can still access the appliance by using the telnet or SSH utility.

I need to reset the NetScaler appliance to the factory defaults. What procedure must I follow?

To reset the NetScaler appliance to the factory defaults, you need to reset two environments: the NetScaler application environment and the base FreeBSD environment. To reset the NetScaler application environment of the appliance to the factory defaults, do the following:

1. Make a backup of the appliance's /nsconfig/ns.conf.
2. Delete the /nsconfig/ns.conf file.
3. Restart the appliance. To reset the FreeBSD environment of the appliance to the factory defaults, do the following:

    a. Install a fresh NetScaler code image on the appliance. This overwrites several FreeBSD-level configuration files with default values.
    b. Delete any users and groups that are added to the appliance, that is, all except the default users.
    c. Delete the /etc/resolv.conf file.
    d. Delete the entries that you have added to the /etc/hosts file.
    e. If the /etc/rc.netscaler file exists, delete it.
    f. Open the /etc/nsperm_group_suser file and make sure that all IOCTL entries are comment entries.
    g. Open the /etc/rc.conf file and make sure that the syslogd_enable=NO entry is not changed to syslogd_enable=YES.
    h. Open the /etc/syslog.conf file and make sure that there are no additional entries in the file.
    i. Delete the contents of the /var/nslog, /var/nstrace, and /var/crash files.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

j. If the syslog process is enabled on the appliance and the appliance creates log files locally, delete the contents of the log files listed in the /etc/syslog.conf file. The files are created in the /var/log directory. For example, if the syslog process writes system events to the /var/log/events file, and `sslvpn` access events to the /var/log/sslvpnevents file, delete these files.

The appliance displays a message similar to the “Jun 21 12:20:18 ns /flash/ns-10.0-47.15: dc0: NIC hangs condition #663: TX 10000/10000, RX 0, HF 0” message on the console. What is the meaning of this message?

The message consists of the following components (shown here as examples):

- #663: Number of times this condition has occurred on the appliance.
- TX 10000/10000: Number of packets that the appliance attempted to transmit, and number of packets transmitted. If both numbers are the same, as in this example, the NIC transmitted all the packets that the appliance attempted to transmit.
- RX 0: Number of packets received. In this example, no packet was received.
- HF0: Number of hardware issues reported by the NIC. In this example, the NIC did not report any hardware issue.

If the appliance does not receive any packets, it reports a hang condition, because on a network it is unlikely not to receive any packets. However, if the appliance is plugged into quite the interface, you can ignore this error message.

After I upgraded the NetScaler release on the appliance, the appliance still displays the earlier release/build. What can be the reason?

The appliance displays the software version number from the /flash/boot/loader.conf file. If the kernel entry for the current NetScaler release is missing from that file, the appliance displays the last NetScaler release version for which the entry was available. To resolve this issue, do the following:

1. Verify that the kernel file exists in the /nsconfig directory.
2. Check the /flash/boot/loader.conf file for an entry for the kernel.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

(You can expect the entry for the kernel of the release/build that you installed to be missing from the file.)

3. Open the loader.conf file in a text editor, such as the vi editor, and update the kernel entry for the new release/build.
4. Save and close the file.
5. Repeat step 2 through step 4 for the /flash/boot/loader.conf.local file.
6. Update the release/build entry in the ns.conf file.
7. Restart the appliance.

Since I upgraded the NetScaler release on the appliance, the LCD display on the front panel of the appliance displays the out of service message or does not display anything. How can I resolve this issue?

Run the following command from the appliance's shell prompt:

```
/netscaler/nslcd –k
```

I have upgraded the NetScaler release/build. However, after the upgrade process, the appliance fails to start. Can I downgrade the appliance's software to the previous release/build?

Yes. You can start the appliance with the kernel.old kernel file. When you restart the appliance, press the F1 key when the appliance console displays the Press F1 message. Type kernel.old and press **Enter**.

After upgrading the NetScaler release on the appliance, I accidentally deleted the kernel file from the /flash directory. As a result, I am not able to start the appliance. Is there a method for starting the appliance in this situation?

Yes. You can start the appliance by using the `kernel.GENERIC` kernel file, as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. When you restart the appliance, press the F1 key when the appliance console displays the Press F1 message.
2. Type kernel. GENERIC and press Enter.
3. Log in as the root user.
4. Reinstall the NetScaler release.
5. Restart the appliance.

After upgrading the appliance software, I am not able to log on to the appliance, and the following message appears. I tried to resolve this issue by using the password recovery procedure, but I was not successful. Have I done something incorrectly?

```
```

```
login: nsroot

Password:

connect: No such file or directory

nsnet_connect: No such file or directory

Login incorrect
```

```
```

You cannot resolve this issue by using the password recovery procedure. NetScaler release 12.1 or later use the new licensing system, based on the `Imgrd` daemon, which runs during the startup procedure. For this daemon to work properly, the host name of NetScaler appliance, which is set in the /nsconfig/rc.conf file, must be resolved by a name server to the NSIP address. Alternately, you can create a hosts file in the /nsconfig directory and add the 127.0.0.1 \<Host_Name> entry in file.

Also, make sure that you have copied the license files to the /nsconfig/license/ directory.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

During an upgrade of a high availability pair, the following message appears repeatedly. What can be the reason?

\<auth.err> ns sshd: error: Invalid user name or password

This error message appears when the appliances involved in the high availability pairing have either a different NetScaler release or a different build of the same release installed. The appliances can have different version installed if you have upgraded or downgraded one appliance but not the other.

I want to change the netmask of the NSIP address on a NetScaler appliance. Can I do so without causing an outage?

Changing the netmask of the NetScaler IP might result in a short outage. Make sure that you change the netmask on the secondary appliance, and then break the high availability pairing. Check the functionality of the appliance. If everything works as expected, rebuild the high availability pairing.

To change the netmask on the appliance, run the `config ns` command from the CLI prompt, and then choose the second option in the menu.

I have configured a High Availability pair of NetScaler appliances. After upgrading the software release from a preview release to a final release, I noticed that some of the appliance configurations are missing. Can I retrieve the lost configurations?

You can use the following procedure to restore the configuration:

1. Log on to the NetScaler command line of the primary appliance.
2. Run the following commands:

```
save config

shell
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
&num;cp /nsconfig/ns.conf /nsconfig/ns.conf.bkup

The ns.conf.bkup file is a backup for the running configuration.
```

3. Upgrade software of both the appliances to the final release.
4. Log on to the NetScaler command line of the primary appliance.

Can the primary appliance and secondary appliance have separate builds?

Recommended practice is to use the same version and build number on both the primary and the secondary appliance.

Can both the appliances in a High Availability (HA) pair be upgraded at the same time?

No. In an HA pair, first upgrade the secondary node and then upgrade the primary node.

For details, refer Upgrading a High Availability Pair.

Does NetScaler support firmware upgrades in the Amazon Web Services cloud?

Yes.

Can I upgrade the NetScaler instance independently of the SDX version?

It is not required to upgrade the SDX version when the NetScaler appliance is upgraded. However, some features might not work.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Can I use the FTP server to upgrade the NetScaler appliance?

No. You must first download the firmware from the NetScaler site, save it on your local computer, and then upgrade the appliance.

Is the procedure for upgrading the NetScaler appliance with GSLB configurations different from an upgrade of an appliance that is not involved in GSLB?

No. The upgrade procedure is similar to the basic upgrade procedure. The only difference is that you can upgrade the standalone or HA appliances on different sites in a phased manner.

Upgrade fails with a warning "Many deprecated features, parameters, and functionalities, and use of classic expressions have been removed". How do I fix this issue?

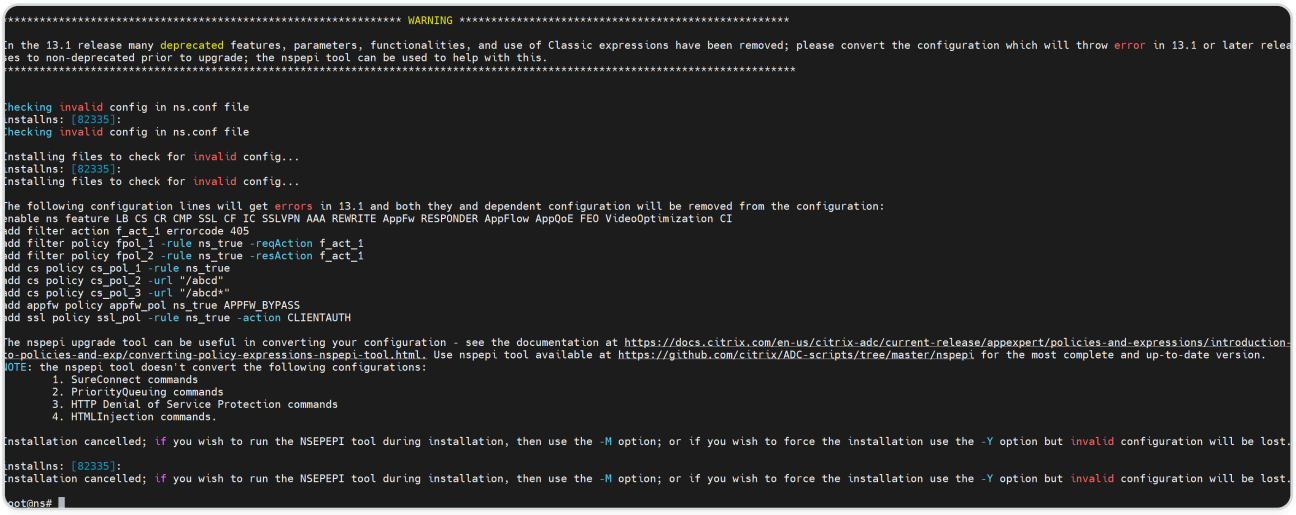
Starting from NetScaler 13.1 release, classic expressions aren't supported in some features. Similarly, some deprecated features are also removed. For more information on deprecated features and commands, see Notice of Status Change Announcement for NetScaler Classic Policy Based Features and Functionalities.

If the configuration contains any command related to the removed features, then the upgrade fails. The removed commands throw errors in releases 13.1 or later and therefore configuration can be lost. Use the `nspepi` tool to convert the invalid or classic configuration to valid or advanced configuration. For information on the `nspepi` tool, see Converting policy expressions using the NSPEPI tool.

NOTE:

If you see an invalid configuration error, we recommend you to use the `-M` option to convert classic policies to advanced policies.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



We do **NOT** recommend you to use the **Y** option while running the `installns` script. If you use the **Y** option, then configuration check does not happen and the invalid configuration can be lost.

Downgrade

I have received a NetScaler appliance with the latest NetScaler release installed on it. However, I want to downgrade the software release. Can I do so?

No. If you attempt to downgrade the software release, the appliance might not work as expected, because the ns.conf file of the later release might not be compatible with the earlier release, and the appliance might restore to the factory settings.

When downgrading the NetScaler release, I followed the instructions. However, the appliance displays the following message. How is the rollback procedure performed on a NetScaler appliance?

```
root@LBCOL03B# ./installns

installns version (10.0-47.7) kernel (ns-10.0-47.7.gz)

Note:

Installation may pause for up to 3 minutes while data is written to the
flash.

Caution:
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Do not interrupt the installation process.

Doing so may cause the system to become unusable.

Installation will proceed in 5 seconds, CTRL-C to abort

No Valid NetScaler Version Detected

root@LBCOL03B#
```

The rollback procedure is similar to the basic upgrade procedure. Select the target build that you want to roll back to and perform the downgrade. Before rolling back to a different release, it is recommended that you create a copy of your current configuration files. To downgrade from a release, see Downgrading a NetScaler Standalone Appliance.

Load Balancing

- **What are the various load balancing policies I can create on the NetScaler appliance?**

  You can create the following types of load balancing policies on the NetScaler appliance:

  - Least Connections
  - Round Robin
  - Least response time
  - Least bandwidth
  - Least packets
  - URL hashing
  - Domain name hashing
  - Source IP address hashing
  - Destination IP address hashing
  - Source IP - Destination IP hashing
  - Token
  - LRTM

- **Can I achieve the Web farm security by implementing load balancing using the NetScaler appliance?**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Yes. You can achieve Web farm security by implementing load balancing using the NetScaler appliance. NetScaler appliance enables you to implement the following options of the load balancing feature:

- IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the NetScaler appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the NetScaler appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

- **What are various devices that I can use to load balance with a NetScaler appliance?**

  You can load balance the following devices with a NetScaler appliance:

  - Server farms
  - Caches or Reverse Proxies
  - Firewall devices
  - Intrusion detection systems
  - SSL offload devices
  - Compression devices
  - Content Inspection servers

- **Why should I implement the load balancing feature for the website?**

  You can implement the Load balancing feature for the website to take the following advantages:

  - Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the back-end server that is not available.

- **Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?**
  - If you enable the MBF option, the NetScaler appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen for the return traffic.
  - Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

- **What are the various persistence types available on the NetScaler appliance?**

  The NetScaler appliance supports the following persistence types:

  - Source IP
  - Cookie insert
  - SSL session ID
  - URL passive
  - Custom Server ID
  - Rule
  - DESTIP

GUI

- **When I use Firefox to compare two NetScaler configurations, the browser seems to freeze?**

  Firefox eventually displays the difference in the configurations, but the process takes a considerable amount of time if there are more than 1000 differences. Use Chrome for a faster response.

- **I am using a MAC Safari browser to upgrade a NetScaler. On the upgrade wizard, when I click the Browse button to choose the build file from the appliance, the dialog box does**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

not show any files or folders. Also, when I navigate back to the root folder, the dialog box displays the top level folder, but I cannot browse it. What should I do?

On the Safari browser, click the Settings icon and navigate to **Preferences > Security > Manage Website Settings > Java**. Change the value of the **When visiting other websites** setting to Run in unsafe mode.

- **What should I do before accessing the GUI?**

  Before accessing a new version of the NetScaler software:

  - Clear browser cache including cookies.
  - Access GUI in browser incognito mode.
  - Access GUI in some other browser.
  - Clear the **Use software acceleration** option in setting and restart the browser.
  - Access **chrome: extensions**, clear the **Enable** box and restart the Chrome browser.

- **Which port should I open to access GUI using HTTP or HTTPS?**

  The following lists the default port numbers for HTTP and HTTPS management services (GUI) in the NetScaler MPX and VPX appliances:

  - NetScaler MPX and VPX appliances: 80 (HTTP) and 443 (HTTPS)

  Also, you can configure ports for HTTP and HTTPS management services (GUI) other than port 80 and 443. For more information, see Configure HTTP and HTTPS management ports.

- **With which browsers is the GUI compatible for different operating systems?**

  The following table lists the compatible browsers for NetScaler GUI version 12.1, 13.0, and 13.1:

OPERATING SYSTEM	BROWSER	VERSIONS
Windows 10 and later	Edge	110.1587.63 and later
Windows 10 and later	Mozilla Firefox	102 and later
Windows 10 and later	Chrome	108 and later
MAC	Mozilla Firefox	110.0.1 and later
MAC	Safari	15.5 and later

SSL

Click here for FAQs about SSL.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Authentication, authorization, and auditing application traffic

Many companies restrict website access to valid users only, and control the level of access permitted to each user. The authentication, authorization, and auditing feature allows a site administrator to manage access controls with the NetScaler appliance instead of managing these controls separately for each application. Doing authentication on the appliance also permits sharing this information across all websites within the same domain that are protected by the appliance.

To use authentication, authorization, and auditing, you must configure authentication virtual servers to handle the authentication process and traffic management virtual servers to handle the traffic to web applications that require authentication. You also configure your DNS to assign FQDNs to each virtual server. After configuring the virtual servers, you configure a user account for each user that will authenticate via the NetScaler appliance, and optionally you create groups and assign user accounts to groups. After creating user accounts and groups, you configure policies that tell the appliance how to authenticate users, which resources to allow users to access, and how to log user sessions. To put the policies into effect, you bind each policy globally, to a specific virtual server, or to the appropriate user accounts or groups. After configuring your policies, you customize user sessions by configuring session settings and binding your session policies to the traffic management virtual server. Finally, if your intranet uses client certs, you set up the client certificate configuration.

To understand how authentication, authorization, and auditing works in a distributed environment, consider an organization with an intranet that its employees access in the office, at home, and when traveling. The content on the intranet is confidential and requires secure access. Any user who wants to access the intranet must have a valid user name and password. To meet these requirements, the ADC does the following:

- Redirects the user to the login page if the user accesses the intranet without having logged in.
- Collects the user's credentials, delivers them to the authentication server, and caches them in a directory that is accessible through the Lightweight Directory Access Protocol (LDAP). For more information, see Determining Attributes in Your LDAP Directory.
- Verifies that the user is authorized to access specific intranet content before delivering the user's request to the application server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Maintains a session timeout after which users must authenticate again to regain access to the intranet. (You can configure the timeout.)
- Logs the user accesses, including invalid login attempts, in an audit log.

Supported authentication types

- Local
- LDAP
- RADIUS
- SAML
- TACACS+
- Client certificate authentication (including smart card authentication)
- Web
- Advanced authentication
- Forms based authentication
- 401 based authentication
- Native OTP
- Push notification
- Email OTP
- reCaptcha

NetScaler Gateway also supports RSA SecurID, Gemalto Protiva, and SafeWord. You use a RADIUS server to configure these types of authentication.

Before configuring authentication, authorization, and auditing, you must be familiar with and understand how to configure load balancing, content switching, and SSL on the NetScaler appliance.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Authentication without authorization

Authorization specifies the network resources to which users have access when they log on to the appliance. The default setting for authorization is to deny access to all network resources. Citrix® recommends using the default global setting and then creating authorization policies to define the network resources users can access.

You configure authorization on the appliance by using an authorization policy and expressions. After you create an authorization policy, you can bind it to the users or groups that you configured on the appliance.

You can configure the appliance to use authentication only, without authorization. When you configure authentication without authorization, the appliance does not perform a group authorization check. The policies that you configure for the user or group are assigned to the user.

Enabling authentication, authorization, and auditing

To use the authentication, authorization, and auditing feature, you must enable it. You can configure authentication, authorization, and auditing entities—such as the authentication and traffic management virtual servers—before you enable the authentication, authorization, and auditing feature, but the entities do not function until the feature is enabled.

To enable authentication, authorization, and auditing by using the CLI

At the command prompt, type the following commands to enable authentication, authorization, and auditing and verify the configuration:

```
enable ns feature AAA
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To enable authentication, authorization, and auditing by using the GUI

1. Navigate to **System > Settings**.
2. In the details pane, under **Modes and Features**, click **Change Basic Features**.
3. In the **Configure Basic Features** dialog box, select the **Authentication, Authorization and Auditing** check box.
4. Click **OK**.

Disabling Authentication

If your deployment does not require authentication, you can disable it. You can disable authentication for each virtual server that does not require authentication.

IMPORTANT:

Important: Citrix recommends disabling authentication with caution. If you are not using an external authentication server, create local users and groups to allow the appliance to authenticate users. Disabling authentication stops the use of authentication, authorization, and accounting features that control and monitor connections to the appliance. When users type a web address to connect to the appliance, the logon page does not appear.

To disable authentication

1. Navigate to **Configuration > NetScaler Gateway > Virtual Servers**.
2. In the details pane, click a virtual server, and then click **Open**.
3. In the **Basic Settings** page, clear the **Enable Authentication** check box.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How authentication, authorization, and auditing works

Authentication, authorization, and auditing provides security for a distributed internet environment by allowing any client with the proper credentials to connect securely to protected application servers from anywhere on the Internet. This feature incorporates the three security features of authentication, authorization, and auditing. Authentication enables the NetScaler to verify the client's credentials, either locally or with a third-party authentication server, and allow only approved users to access protected servers. Authorization enables the ADC to verify which content on a protected server it allows each user to access. Auditing enables the ADC to keep a record of each user's activity on a protected server.

To understand how authentication, authorization, and auditing works in a distributed environment, consider an organization with an intranet that its employees access in the office, at home, and when traveling. The content on the intranet is confidential and requires secure access. Any user who wants to access the intranet must have a valid user name and password. To meet these requirements, the ADC does the following:

- Redirects the user to the login page if the user accesses the intranet without having logged in.
- Collects the user's credentials, delivers them to the authentication server, and caches them in a directory that is accessible through LDAP. For more information, see Determining Attributes in Your LDAP Directory.
- Verifies that the user is authorized to access specific intranet content before delivering the user's request to the application server.
- Maintains a session timeout after which users must authenticate again to regain access to the intranet. (You can configure the timeout.)
- Logs the user accesses, including invalid login attempts, in an audit log.

Configure authentication authorization and auditing policies

After you set up your users and groups, you next configure authentication policies, authorization policies, and audit policies to define which users are allowed to access your intranet, which resources each user or group is allowed to access, and what level of detail authentication, authorization, and auditing will preserve in the audit logs. An authentication policy defines the type of authentication to apply when a user attempts to log on. If external authentication is used, the policy also specifies the external authentication server. Authorization policies specify the network

© 1997–2026 Citrix Systems, Inc. All rights reserved.

resources that users and groups can access after they log on. Auditing policies define the audit log type and location.

You must bind each policy to put it into effect. You bind authentication policies to authentication virtual servers, authorization policies to one or more user accounts or groups, and auditing policies both globally and to one or more user accounts or groups.

When you bind a policy, you assign a priority to it. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer. In the NetScaler operating system, policy priorities work in reverse order: the higher the number, the lower the priority. For example, if you have three policies with priorities of 10, 100, and 1000, the policy assigned a priority of 10 is performed first, then the policy assigned a priority of 100, and finally the policy assigned an order of 1000. The authentication, authorization, and auditing feature implements only the first of each type of policy that a request matches, not any additional policies of that type that a request might also match, so policy priority is important for getting the results you intend.

You can leave yourself plenty of room to add other policies in any order, and still set them to evaluate in the order you want, by setting priorities with intervals of 50 or 100 between each policy when you bind the policies. You can then add additional policies at any time without having to reassign the priority of an existing policy.

For additional information about binding policies on the NetScaler appliance, see the NetScaler product documentation.

Configure the No_Auth policy to bypass certain traffic

You can now configure No_Auth policy to bypass certain traffic from authentication when 401-based authentication is enabled on traffic management virtual server. For such traffic, you must bind a “No_Auth” policy.

To configure the No_Auth policy to bypass certain traffic by using the CLI

At the command prompt, type:

```
add authentication policy <name> -rule <expression> -action <string>
```

Example:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication policy ldap -rule ldapAct1 -action No_Auth
```

Basic components of authentication, authorization, and auditing configuration

The basic components of the authentication, authorization, and auditing configuration are as follows:

- **Authentication virtual server** - All authentication requests are redirected by the traffic management virtual server (load balancing or content switching) to the authentication virtual sever. This virtual server processes the associated authentication policies and accordingly provides access to the application. For details, see Authentication virtual server.
- **Authentication profiles** - An authentication profile specifies the authentication virtual server, the authentication host, the authentication domain, and an authentication level.

You can create one or more authentication profiles to specify different authentication settings and bind these authentication profiles to relevant traffic management servers based on your requirements. For details, see Authentication profiles.

- **Authentication policies** - When users log on to the NetScaler or NetScaler Gateway appliance, they are authenticated according to a policy that you create. An authentication policy comprises of an expression and an action. Authentication policies use NetScaler expressions. For details, see Authentication policies.
- **Authorization policies** - When you configure an authorization policy, you can set it to allow or deny access to network resources in the internal network. For details, see Authorization policies.
- **Users and groups:** - After configuring the authentication, authorization, and auditing basic setup, you create users and groups. You first create a user account for each person who will authenticate via the NetScaler appliance. If you are using local authentication controlled by the NetScaler appliance itself, you create local user accounts and assign passwords to each of those accounts. For details, see Users and groups.

Authentication virtual server

The traffic management virtual server (load balancing or content switching) redirects all authentication requests to the authentication virtual server. This virtual server processes the associated authentication policies and accordingly provides access to the application.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Note: You cannot bind traffic management policies to authentication, authorization, and auditing virtual servers.

Set up authentication virtual server

The steps involved in setting up an authentication virtual server are;

1. Enable the authentication, authorization, and auditing feature.

   ```
   enable ns feature AAA
   ```

2. Configure an authentication virtual server. It must be of type SSL and make sure to bind the SSL certificate-key pair to the virtual server.

   ```
   add authentication vserver <name> SSL <ipaddress> <port>

   bind ssl certkey <auth-vserver-name> <certkey>
   ```

3. Specify the FQDN of the domain for the authentication virtual server.

   ```
   set authentication vserver <name> -authenticationDomain <FQDN>
   ```

4. Associate the authentication virtual server to the relevant traffic management virtual server.

   Points to Note:

   - The FQDN of the traffic management virtual server must be in the same domain as the FQDN of the authentication virtual server for the domain session cookie to function correctly. On the traffic management virtual server:
     - Enable authentication.
     - Specify the FQDN of the authentication virtual server as the authentication host of the traffic management virtual server.
     - Specify the authentication domain on the traffic management virtual server.
     - If you do not configure the authentication domain, the appliance assigns an FQDN that consists of the FQDN of the authentication virtual server without the host name portion.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For example, if the domain name of the authentication virtual server is **tm.xyz.bar.com**, the appliance assigns **xyz.bar.com** as the authentication domain.

- For load balancing:

```
set lb vserver <name> -authentication ON -authenticationhost
<FQDN> [-authenticationdomain <authdomain>]
```

NOTE:

When authentication is enabled, an unauthenticated POST request to the load balancing virtual server has a POST body limited to 4096 bytes. If the request exceeds this limit, the POST body is truncated to the allowed size after authentication. This truncation might cause the POST request to fail on the backend server. To increase the default size limit, contact Citrix Support.

- For content switching:

```
set cs vserver <name> <protocol> <IPAddress> <port>
```

- If you have to set a domain wide cookie for an authentication domain, you must enable authentication profile on a load balancing virtual server.

5. Verify that both the virtual servers are UP and configured correctly.

```
show authentication vserver <name>
```

NOTE:

To use the authentication virtual server in a non-default partition, run the following command in the shell:

```
nsapimgr_wr.sh -ys call=toggle_vpn_httpd_partition_support
```

When you enable the authentication virtual server in a non-default partition, NetScaler Gateway generates an info log in `/var/log/ns.log`. The following is an example of a sample info log file:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Jun 21 12:25:56 &lt;local0.info> x.x.x.x  06/21/2023:11:25:56 GMT  0-
PPE-0 : default SSLVPN Message 837 0 :  "vpn httpd partition support value
is changed from 0 to 1"

Jun 21 12:25:56 &lt;local0.info> x.x.x.x  06/21/2023:11:25:56 GMT  0-
PPE-1 : default SSLVPN Message 1090 0 :  "vpn httpd partition support
value is changed from 0 to 1"

Jun 21 12:25:56 &lt;local0.info> x.x.x.x  06/21/2023:11:25:56 GMT  0-
PPE-2 : default SSLVPN Message 676 0 :  "vpn httpd partition support value
is changed from 0 to 1"
```

Run the same command again to disable the authentication virtual server in a non-default partition. This feature is disabled by default.

To set up an authentication virtual server by using the GUI

1. Enable the authentication, authorization, and auditing feature.

   Navigate to **System > Settings**, click **Configure Basic features**, and enable **Authentication, Authorization and Auditing**.

2. Configure the authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and configure as required.

3. Configure the traffic management virtual server for authentication.

   - **For load balancing:**

     Navigate to **Traffic Management > Load Balancing > Virtual Servers**, and configure the virtual server as required.

   - **For content switching:**

     Navigate to **Traffic Management > Content Switching > Virtual Servers**, and configure the virtual server as required.

4. - Verify the authentication setup.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and check the details of the relevant authentication virtual server.

Configure the authentication virtual server

To configure authentication, authorization, and auditing, first configure an authentication virtual server to handle authentication traffic. Next, bind an SSL certificate-key pair to the virtual server to enable it to handle SSL connections. For additional information about configuring SSL and creating a certificate-key pair, see SSL certificates.

Configure an authentication virtual server by using the CLI

To configure an authentication virtual server and verify the configuration, at the command prompt type the following commands in the same order:

```
add authentication vserver <name> ssl <ipaddress>

show authentication vserver <name>

bind ssl certkey <certkeyName>

show authentication vserver <name>

set authentication vserver <name>

show authentication vserver <name>
```

Example:

```
add authentication vserver Auth-Vserver-2 SSL 10.102.29.77 443 Done
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show authentication vserver Auth-Vserver-2 Auth-Vserver-2
(10.102.29.77:443) - SSL Type: CONTENT State: DOWN[Certkey not bound]
Client Idle Timeout: 180 sec Down state flush: DISABLED Disable Primary
Vserver On Down : DISABLED Authentication : ON Current AAA Users: 0 Done

bind ssl certkey Auth-Vserver-2 Auth-Cert-1 Done

show authentication vserver Auth-Vserver-2 Auth-Vserver-2
(10.102.29.77:443) - SSL Type: CONTENT State: UP Client Idle Timeout: 180
sec Down state flush: DISABLED Disable Primary Vserver On Down : DISABLED
Authentication : ON Current AAA Users: 0 Done

set authentication vserver Auth-Vserver-2

show authentication vserver Auth-Vserver-2 Auth-Vserver-2
(10.102.29.77:443) - SSL Type: CONTENT State: DOWN[Certkey not bound]
Client Idle Timeout: 180 sec Down state flush: DISABLED Disable Primary
Vserver On Down : DISABLED Authentication : ON Current AAA Users: 0 Done
```

NOTE

The Authentication Domain parameter is deprecated. Use Authentication Profile for setting domain wide cookies.

Configure an authentication virtual server by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Virtual Servers**.
2. In the details pane, do one of the following:
   - To create a new authentication virtual server, click **Add**.
   - To modify an existing authentication virtual server, select the virtual server, and then click **Edit**. The Configuration dialog opens with the Basic Settings area expanded.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Specify values for the parameters as follows (asterisk indicates a required parameter):

   - Name*—name (Cannot be changed for a previously created virtual server)
   - IP Address Type*—IP address type of the authentication virtual server
   - IP Address*—IP address of the authentication virtual server
   - Port*—TCP port on which the virtual server accepts connections.
   - Failed login timeout—failedLoginTimeout (Seconds allowed before login fails, and user must start login process again.)
   - Max login attempts—maxLoginAttempts (Number of login attempts allowed before user is locked out)

   NOTE:

   The authentication virtual server uses only the SSL protocol and port 443, so those options are grayed out. Any options that are not mentioned can be ignored.

4. Click **Continue** to display the Certificates area.
5. In the **Certificates** area, configure any SSL certificates you want to use with this virtual server.

   - To configure a CA certificate, click the arrow on the right of CA Certificate to display the CA Cert Key dialog box, select the certificate you want to bind to this virtual server, and click **Save**.
   - To configure a server certificate, click the arrow on the right of Server Certificate, and follow the same process as for the CA certificate.

6. Click **Continue** to display the **Advanced Authentication Policies** area.
7. If you want to bind an advanced authentication policy to the virtual server, click the arrow on the right side of the line to display the **Authentication Policy** dialog box, choose the policy that you want to bind to the server, set the priority, and then click **OK**.
8. Click **Continue** to display the **Basic Authentication Policies** area.
9. If you want to create a basic authentication policy and bind it to the virtual server, click the plus sign to display the **Policies** dialog box, and follow the prompts to configure the policy and bind it to this virtual server.
10. Click **Continue** to display the 401-Based Virtual Servers area.
11. In the 401-Based Virtual Servers area, configure any load balancing or content switching virtual servers that you want to bind to this virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To bind a load balancing virtual server, click the arrow to the right of load balancing virtual server to display the Load Balancing Virtual Servers dialog box, and follow the prompts.
- To bind a content switching virtual server, click the arrow to the right of content switching virtual server to display the Content Switching Virtual Servers dialog box, and follow the same process as to bind an LB virtual server.

12. If you want to create or configure a group, in the Groups area click the arrow to display the Groups dialog box, and follow the prompts.
13. Review your settings, and when you are finished, click **Done**. The dialog box closes. If you created a new authentication virtual server, it now appears in the **Configuration** window list.

Traffic management virtual server

After you have created and configured your authentication virtual server, you next create or configure a traffic management virtual server and associate your authentication virtual server with it. You can use either a load balancing or content switching virtual server for a traffic management virtual server.

NOTE:

The FQDN of the traffic management virtual server must be in the same domain as the FQDN of the authentication virtual server for the domain session cookie to function correctly.

You configure a traffic management virtual server for authentication, authorization, and auditing by enabling authentication and then assigning the FQDN of the authentication server to the traffic management virtual server. You can also configure the authentication domain on the traffic management virtual server currently. If you do not configure this option, the NetScaler appliance assigns the traffic management virtual server an FQDN that consists of the FQDN of the authentication virtual server without the host name portion. For example, if the domain name of the authentication virtual server is tm.xyz.bar.com, the appliance assigns xyz.bar.com. as the authentication domain.

To configure a traffic management virtual server by using the CLI

At the command prompt, type one of the following sets of commands:

```
set lb vserver <name> –authentication ON -authenticationhost <FQDN> [-
authenticationdomain <authdomain>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show lb vserver <name>

set cs vserver <name> –authentication ON -authenticationhost <FQDN> [-
authenticationdomain <authdomain>]

show cs vserver <name>
```

Example:

```
set lb vserver vs-cont-sw -Authentication ON -AuthenticationHost
mywiki.index.com Done

show lb vserver vs-cont-sw vs-cont-sw (0.0.0.0:0) - TCP Type: ADDRESS
State: DOWN Last state change was at Wed Aug 19 10:03:15 2009 (+410 ms)
Time since last state change: 5 days, 20:00:40.290 Effective State: DOWN
Client Idle Timeout: 9000 sec Down state flush: ENABLED Disable Primary
Vserver On Down : DISABLED No. of Bound Services : 0 (Total) 0 (Active)
Configured Method: LEASTCONNECTION Mode: IP Persistence: NONE Connection
Failover: DISABLED Authentication: ON Host: mywiki.index.com

Done
```

To configure a traffic management virtual server by using the GUI

1. In the navigation pane, do one of the following.
    - Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
    - Navigate to **Traffic Management > Content Switching > Virtual Servers**
    - In the details pane, select the virtual server on which you want to enable authentication, and then click **Edit**.
    - In the Domain text box, type the authentication domain.
    - In the **Advanced** menu on the right, select **Authentication**.
    - Choose either **Form Based Authentication** or **401 Based Authentication**, and fill in the Authentication information.
        - For Form Based Authentication, enter the Authentication FQDN (the fully qualified domain name of the authentication server), the Authentication virtual server (the IP

© 1997–2026 Citrix Systems, Inc. All rights reserved.

address of the authentication virtual server), and the Authentication Profile (the profile to use for authentication).

- For 401 Based Authentication, enter the Authentication virtual server and the Authentication Profile only.

- Click **OK**. A message appears in the status bar, stating that the virtual server has been configured successfully.

Simplified login protocol support for authentication, authorization, and auditing

The login protocol between authentication, authorization, and auditing traffic management virtual servers and authentication, authorization, and auditing virtual servers is simplified to use internal mechanisms as opposed to sending the encrypted data through query parameters. Using this feature, the replay of requests is prevented.

Configure DNS

For the domain session cookie used in the authentication process to function correctly, you must configure DNS to assign both the authentication and the traffic management virtual servers to FQDNs in the same domain. For information about how to the configure DNS address records, see Domain Name System.

Verify authentication virtual server

After you configure authentication and traffic management virtual servers and before you create user accounts, you must verify that both virtual servers are configured correctly and are in the UP state.

Configure a noAuth authentication by using the CLI

At the command prompt, type the following command:

```
show authentication vserver <name>
```

Example:

```
show authentication vserver Auth-Vserver-2

Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
State: UP

Client Idle Timeout: 180 sec

Down state flush: DISABLED

Disable Primary Vserver On Down : DISABLED

Authentication : ON

Current AAA Users: 0

Authentication Domain: myCompany.employee.com

Done
```

Configure a noAuth authentication by using the GUI

1. Navigate to **Security > NetScaler AAA - Application Traffic > Virtual Servers**. Note: From NetScaler Gateway, navigate to **NetScaler Gateway > Virtual Servers**.
2. Review the information in the **AAA Virtual Servers** pane to verify that your configuration is correct and your authentication virtual server is accepting traffic. You can select a specific virtual server to view detailed information in the details pane.

Authorization policies

When you configure an authorization policy, you can set it to allow or deny access to network resources in the internal network. For example, to allow users access to the 10.3.3.0 network, use the following expression:

CLIENT.IP.DST.IN_SUBNET(10.3.0.0/16)

Authorization policies are applied to users and groups. After a user is authenticated, NetScaler Gateway performs a group authorization check by obtaining the user's group information from either an RADIUS, LDAP, or TACACS+ server. If group information is available for the user, NetScaler Gateway checks the network resources allowed for the group.

To control which resources users can access, you must create authorization policies. If you do not need to create authorization policies, you can configure default global authorization.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If you create an expression within the authorization policy that denies access to a file path, you can only use the subdirectory path and not the root directory. For example, use fs.path contains "\\\ \dir1\\\\dir2" instead of fs.path contains "\\\\rootdir\\\\dir1\\\\dir2". If you use the second version in this example, the policy fails.

After you configure the authorization policy, you then bind it to a user or group.

By default, authorization policies are validated first against policies that you bind to the virtual server and then against policies bound globally. If you bind a policy globally and want the global policy to take precedence over a policy that you bind to a user, group, or virtual server, you can change the priority number of the policy. Priority numbers start at zero. A lower priority number gives the policy higher precedence.

For example, if the global policy has a priority number of one and the user has a priority of two, the global authentication policy is applied first.

IMPORTANT:

- Classic authorization policies are applied only on TCP traffic.
- Advanced authorization policy can be applied on all types of traffic (TCP/UDP/ICMP/DNS).
  - To apply policy on UDP/ICMP/DNS traffic, policies must be bound at type UDP_REQUEST, ICMP_REQUEST, and DNS_REQUEST respectively.
  - While binding, if "type" is not explicitly mentioned or "type" is set to REQUEST, the behavior does not change from earlier builds, that is these policies are applied only to TCP traffic.
  - The policies bound at UDP_REQUEST do not apply for DNS traffic. For DNS, policies must be explicitly bound to DNS_REQUEST TCP_DNS is similar to other TCP requests.

For more details on advanced authorization policies, see article `<https://support.citrix.com/article/CTX232237>`.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure and bind an authorization policy

Configure an authorization policy by using the GUI

1. Navigate to **NetScaler Gateway > Policies > Authorization.**
2. In the details pane, click **Add**.
3. In **Name**, type a name for the policy.
4. In **Action**, select **Allow** or **Deny**.
5. In **Expression**, click **Expression Editor**.
6. To configure the expressions, click **Select** and choose the necessary elements. Following are a few expression examples,

   - `HTTP.REQ.USER.IS_MEMBER_OF(\"AllowedGroup\")` - You can allow or deny access to a user if the user is member of the user group "AllowedGroup".
   - `CLIENT.IP.DST.BETWEEN(10.102.75.10,10.102.75.20)` - You can allow or deny access if the client destination IP address is within a certain range.
   - `HTTP.REQ.HOSTNAME.CONTAINS(\"portal-srv") || CLIENT.IP.DST.IN_SUBNET(10.102.75.0/25)` - You can allow or deny access to the user if the hostname of their HTTP request contains the text "portal-serv" or if the client device destination IP address is in the subnet 10.102.75.0/25.

7. Click **Done** when your expression is complete.
8. Click **Create**.

Bind an authorization policy to a user by using the GUI

1. Navigate to **NetScaler Gateway > User Administration.**
2. Click **AAA Users**.
3. In the details pane, select a user and then click **Edit**.
4. In **Advanced Settings**, click **Authorization Policies**.
5. In **Policy Binding** page, select a policy or create a policy.
6. In **Priority**, set the priority number.
7. In **Type**, select the request type and then click **OK**.

Bind an authorization policy to a group by using the GUI

1. Navigate to **NetScaler Gateway > User Administration**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. Click **AAA Groups**.
3. In the details pane, select a group and then click **Edit**.
4. In **Advanced Settings**, click **Authorization Policies**.
5. In **Policy Binding** page, select a policy or create a policy.
6. In **Priority**, set the priority number.
7. In **Type**, select the request type and then click **OK**.

Authorization specifies the network resources to which users have access when they log on to NetScaler Gateway. The default setting for authorization is to deny access to all network resources. Citrix recommends using the default global setting and then creating authorization policies to define the network resources users can access.

You configure authorization on NetScaler Gateway by using an authorization policy and expressions. After you create an authorization policy, you can bind it to the users or groups that you configured on the appliance.

Default global authorization

To define the resources to which users have access on the internal network, you can configure default global authorization. You configure global authorization by allowing or denying access to network resources globally on the internal network.

Any global authorization action you create is applied to all users who do not already have an authorization policy associated with them, either directly or through a group. A user or group authorization policy always overrides the global authorization action. If the default authorization action is set to Deny, you must apply authorization policies for all users or groups to make network resources accessible to those users or groups. This requirement helps to improve security.

To set default global authorization:

1. In the configuration utility, on the Configuration tab, in the navigation pane, expand NetScaler Gateway and then click Global Settings.
2. In the details pane, under Settings, click Change global settings.
3. On the Security tab, next to Default Authorization Action, select Allow or Deny then and click OK.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Authentication profiles

When you want the same authentication settings to be used by multiple traffic management virtual servers, you can create an authentication profile which specifies the authentication virtual server, the authentication host, the authentication domain, and the authentication level.

This authentication profile can be associated with the relevant traffic management virtual servers.

Configure an authentication profile

Configure an authentication profile by using the CLI

- Create the authentication profile and set the required parameters.

  For example, to create a profile with an authentication virtual server named "authVS".

```
add authentication authnProfile authProfile1 -authnVsName authVS
-authenticationHost authnVS.example.com -authenticationDomain
example.com -authenticationLevel
```

NOTE:

The authentication weight or level depends on the virtual server to which the traffic is bound. A session that is created by authenticating against the traffic management virtual server at a given level cannot be used to access the traffic management virtual server at a higher level.

- Bind the authentication profile to the relevant traffic management virtual servers.

  For example, to bind authProfile1 to a load balancing virtual server named "vserver1".

```
set lb vserver vserver1 -authnProfile authProfile1
```

Configure an authentication profile by using the GUI

In the **Configuration** tab, navigate to **Security > AAA - Application Traffic > Authentication Profile**, and configure the authentication profile as required.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- You can create an authentication profile by using the NetScaler Gateway wizard as well. The profile contains all the settings for the authentication policy. You configure the profile when you create the authentication policy.
- With the NetScaler Gateway wizard, you can use the chosen authentication type to configure authentication. If you want to configure other authentication policies after running the wizard, you can use the configuration utility. For more information about the NetScaler Gateway wizard, see Configuring Settings by Using the NetScaler Gateway Wizard].

Authentication policies

When users log on to NetScaler or NetScaler Gateway, they are authenticated according to a policy that you create. An authentication policy comprises an expression and an action. Authentication policies use NetScaler expressions.

After creating an authentication action and an authentication policy, bind it to an authentication virtual server and assign a priority to it. When binding it, also designate it as either a primary or a secondary policy. Primary policies are evaluated before secondary policies. In configurations that use both types of policy, primary policies are normally more specific policies while secondary policies are normally more general policies. It is intended to handle authentication for any user accounts that do not meet the more specific criteria. The policy defines the authentication type. A single authentication policy can be used for simple authentication needs and is typically bound at the global level. You can also use the default authentication type, which is local. If you configure local authentication, you must also configure users and groups on NetScaler.

You can configure multiple authentication policies and bind them to create a detailed authentication procedure and virtual servers. For example, you can configure cascading and two-factor authentication by configuring multiple policies. You can also set the priority of the authentication policies to determine which servers and the order in which NetScaler checks user credentials. An authentication policy includes an expression and an action. For example, if you set the expression to True value, when users log on, the action evaluates user logon to true and then users have access to network resources.

After you create an authentication policy, you bind the policy at either the global level or to virtual servers. When you bind at least one authentication policy to a virtual server, any authentication policies that you bound to the global level are not used when users log on to the virtual server,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

unless the global authentication type has a higher precedence than the policy bound to the virtual server.

When a user logs on to NetScaler, authentication is evaluated in the following order:

- The virtual server is checked for any bound authentication policies.
- If authentication policies are not bound to the virtual server, NetScaler checks for global authentication policies.
- If an authentication policy is not bound to a virtual server or globally, the user is authenticated through the default authentication type.

If you configure LDAP and RADIUS authentication policies and want to bind the policies globally for two-factor authentication, you can select the policy in the configuration utility and then select if the policy is the primary or secondary authentication type. You can also configure a group extraction policy.

NOTE:

NetScaler or NetScaler Gateway encodes only UTF-8 characters for authentication, and it is not compatible with servers that use ISO-8859-1 characters.

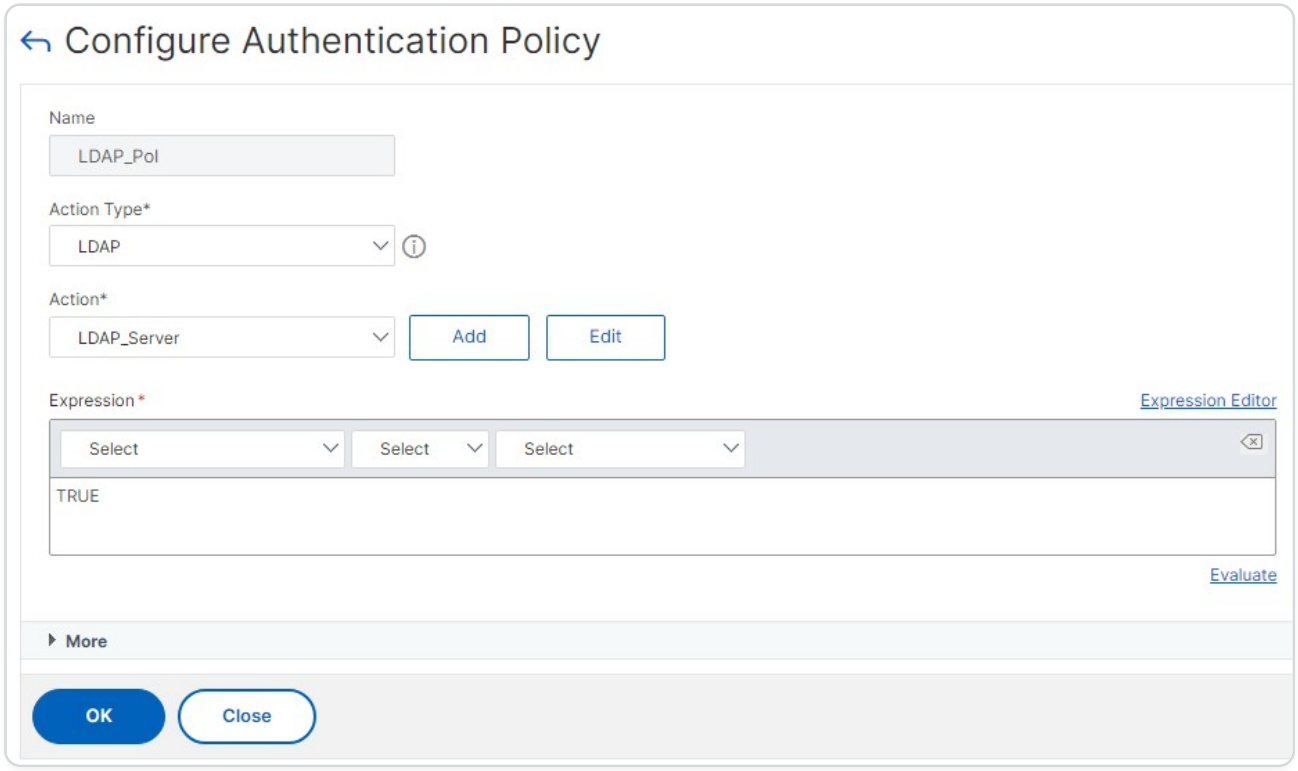
On the GUI

Create or modify an advanced authentication policy

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**.
2. On the **Authentication Policies** page, perform one of the following tasks:
   - To create an authentication policy, click **Add**. The **Create Authentication Policy** page appears.
   - Update the required fields and click **Create**.
   - To modify an authentication policy, select the action, and then click **Edit**. The **Configure Authentication Policy** page is displayed. Modify the required fields and click **OK**.
     - **Name**: Name of the advanced authentication policy.
     - **Action Type**: The type of the authentication action for which the policy is being created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Action**: Name of the authentication action (LDAP, RADIUS, SAML) to be performed if the policy matches. If there is no authentication action in the drop-down list, click **Add**.
- **Expression**: Name of the NetScaler named rule or expression that the policy uses to determine whether to attempt to authenticate the user with the authentication virtual server. For more information about advanced policy expressions, see Advanced policy expressions.



Remove an authentication policy

If you have changed or removed an authentication server from your network, remove the corresponding authentication policy from NetScaler.

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**.
2. On the **Authentication Policies** page, select the policy that you want to remove and click **Delete**.
3. Click **Yes** to confirm your action.

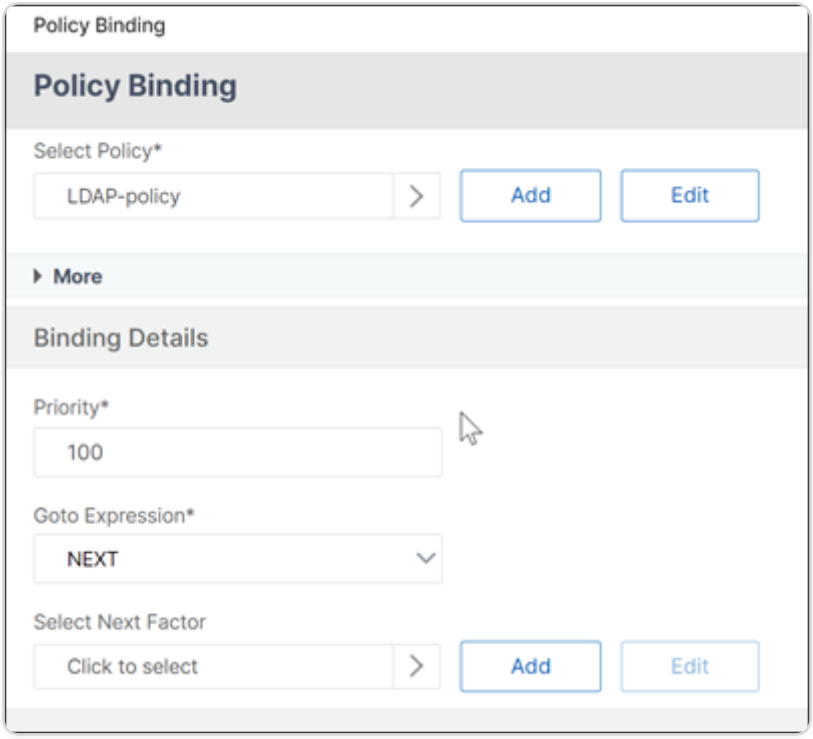
Bind the authentication policy

You must bind advanced authentication policies to an authentication virtual server and link the authentication virtual server to a VPN virtual server by using an authentication profile.

1. Create an authentication virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

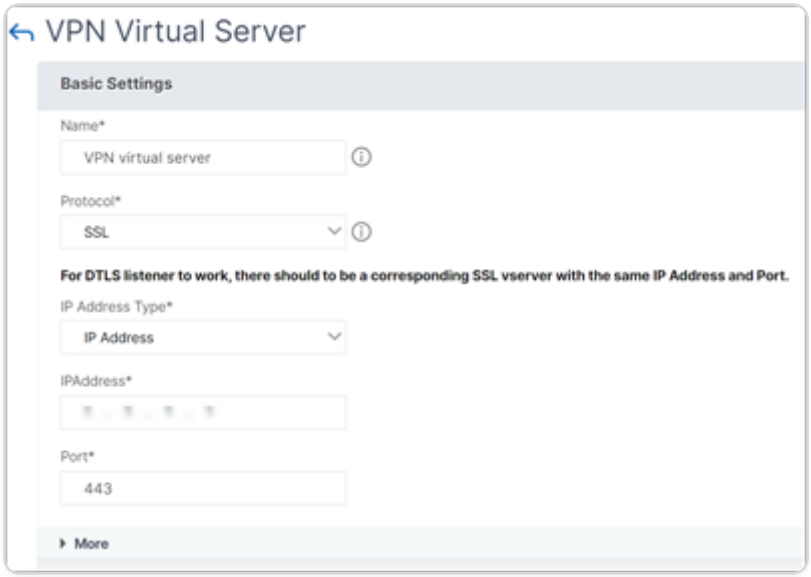
- Navigate to **Security > AAA - Application Traffic > Virtual Servers**.
- On the **Authentication Virtual Servers** page, and click **Add**. Update the required fields and click **OK**.
- If an authentication virtual server exists, select the relevant server on the **Authentication Virtual Servers** page.
- In the **Advanced Authentication Policies** section, select the authentication policy.
- On the **Policy Binding** page, select the policy and click **Add**. Provide the binding details such as the priority, GoTo expression, and the next factor, and then click **Bind**.



1. Create a VPN virtual server.

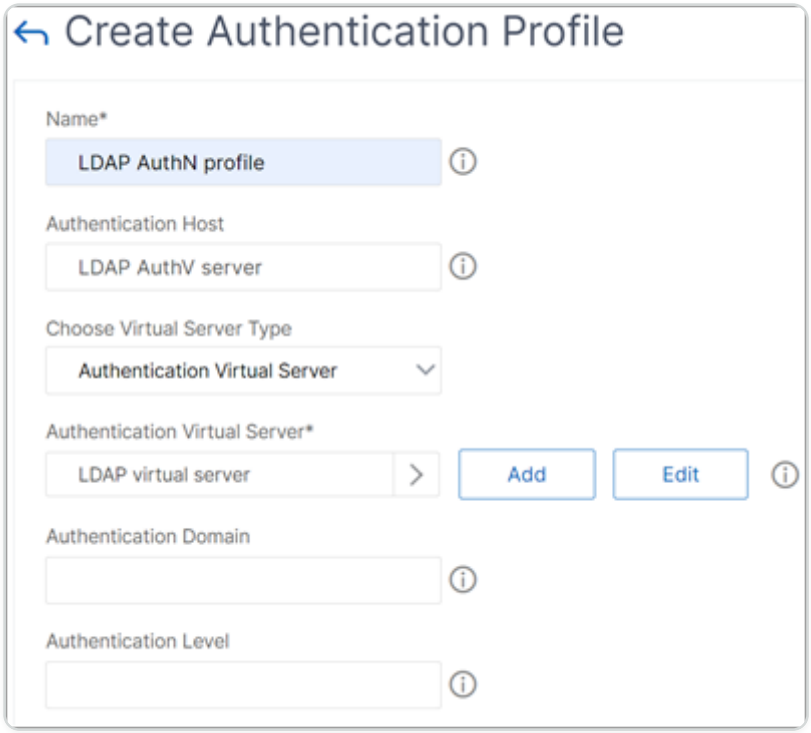
   - Navigate to **NetScaler Gateway > Virtual servers**.
   - On the **NetScaler Gateway Virtual Servers** page, click **Add**.
   - On the **VPN Virtual Server** page, update the required fields and click **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. Create an authentication profile.

   - Navigate to **Security > AAA - Application Traffic > Authentication Profile**.
   - On the **Authentication Profile** page, click **Add**.
   - Update the required fields and click **Create**.

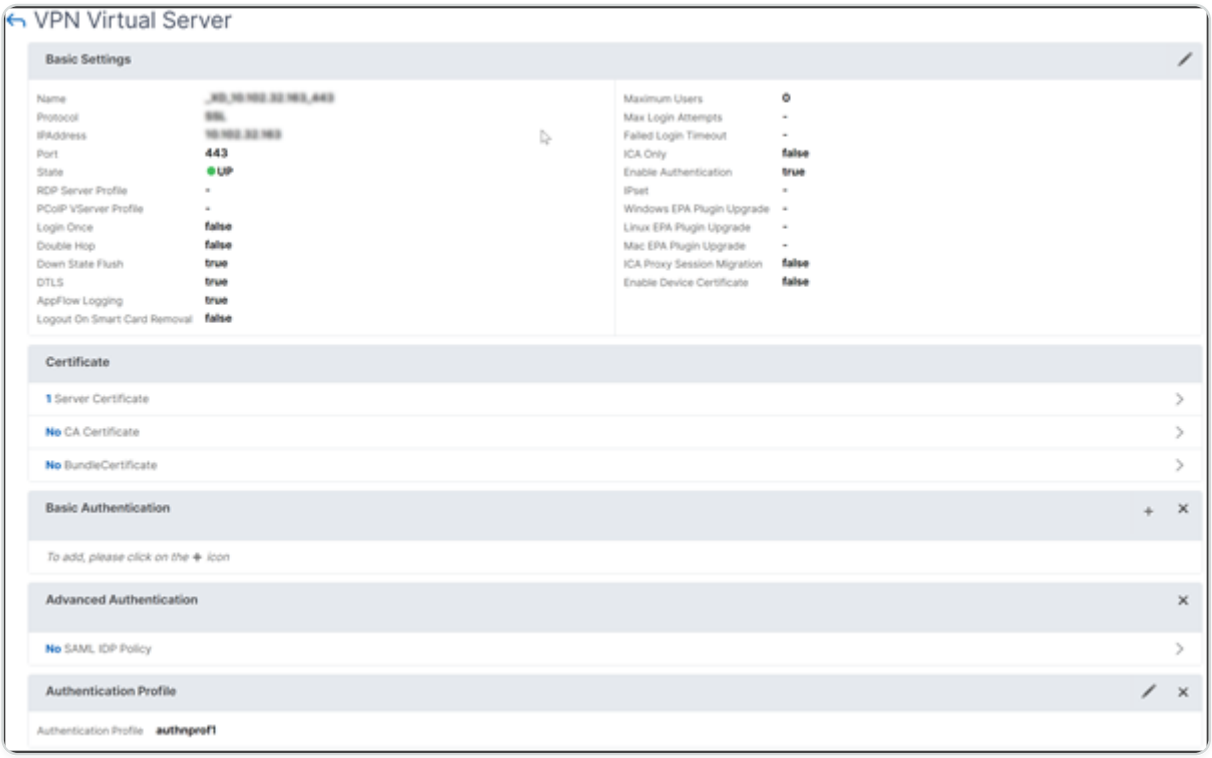


3. Link the authentication virtual server to the VPN virtual server by using the authentication profile.

   - Navigate to **NetScaler Gateway > NetScaler Gateway Virtual Servers** and select the VPN virtual server. The **VPN Virtual Server** page appears.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- In the **Authentication profile** section, select the authentication profile from the drop-down list and click **OK**.
- Alternatively, you can navigate to the **Advanced settings** section on the **VPN Virtual server** page, click **+ Authentication Profile**, select the authentication profile from the drop-down list, and click **OK**.
- Click **Done**.



On the CLI

At the command prompt, type the following commands:

```
add authentication policy <name> -rule <expression> -action <string>

show authentication policy <name>

bind authentication vserver <name> -policy <policyname> [-priority
<priority>][-secondary]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show authentication vserver <name>
```

Example:

```
add authentication policy Authn-Pol-1 true

show authentication policy Authn-Pol-1

Name: Authn-Pol-1       Rule: true          Request action: LOCAL

bind authentication vserver Auth-Vserver-2 -policy Authn-Pol-1

show authentication vserver Auth-Vserver-2

Auth-Vserver-2 (10.102.29.77:443) - SSL Type: CONTENT State: UP Client
Idle

Timeout: 180 sec Down state flush: DISABLED

Disable Primary Vserver On Down : DISABLED

Authentication : ON

Current AAA Users: 0

Authentication Domain: myCompany.employee.com

Primary authentication policy name:  Authn-Pol-1 Priority: 0
```

Modify an authentication policy

At the command prompt, type the following commands to modify an existing authentication policy:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication policy <name> [-rule <expression>] [-action <string>]
[-undefAction <string>] [-comment <string>] [-logAction <string>]
```

Example

```
set authentication policy Authn-Pol-1 -rule true
```

Remove an authentication policy

At the command prompt, type the following command to remove an authentication policy:

```
rm authentication policy <name>
```

Example

```
rm authentication localPolicy Authn-Pol-1
```

Bind the authentication policy

For advanced policies, create an authentication profile and associate the profile to an authentication virtual server. Once the authentication profile is created, associate the authentication profile to a VPN virtual server.

Create an authentication profile and set an authentication virtual server to the profile:

```
 add authentication authnProfile <name> {-authnVsName <string>} {-
AuthenticationHost <string>}{-AuthenticationDomain <string>}[-
AuthenticationLevel <positive_integer>]
```

Example

```
 add authentication authnProfile Authn-Prof-1 -authnVsName Auth-Vserver-2
-AuthenticationDomain "myCompany.employee.com"
```

Create a VPN virtual server and add the corresponding authentication profile:

Example

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add vpn vserver VPN-Vserver-2 ssl -authentication ON -authnprofile Authn-
Prof-1
```

Add an authentication action

If you do not use LOCAL authentication, you need to add an explicit authentication action. At the command prompt, type the following command:

```
add authentication tacacsAction <name> -serverip <IP> [-serverPort <port>]
[-authTimeout <positive_integer>][ ... ]
```

Example

```
add authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65
-serverport 1812 -authtimeout 15 -tacacsSecret "minotaur" -authorization
OFF -accounting ON -auditFailedCmds OFF -defaultAuthenticationGroup
"users"
```

Configure an authentication action

To configure an existing authentication action, at the command prompt, type the following command:

```
set authentication tacacsAction <name> -serverip <IP> [-serverPort <port>]
[-authTimeout <positive_integer>][ ... ]
```

Example

```
set authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65
-serverport 1812 -authtimeout 15 -tacacsSecret "minotaur" -authorization
OFF -accounting ON -auditFailedCmds OFF -defaultAuthenticationGroup
"users"
```

Remove an authentication action

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Example

```
rm authentication tacacsaction Authn-Act-1
```

The noAuth authentication

NetScaler supports noAuth authentication capability that enables the customer to configure a defaultAuthenticationGroup parameter in the `noAuthAction` command, when a user performs this policy. The administrator can check for the presence of this group in the user's group to determine the user's navigation through the noAuth policy.

To configure a noAuth authentication

At the command prompt, type;

```
add authentication noAuthAction <name> [-defaultAuthenticationGroup
<string>]
```

Example

```
add authentication noAuthAction noauthact –defaultAuthenticationGroup
mynoauthgroup
```

Default global authentication types

When you installed NetScaler Gateway and ran the NetScaler Gateway wizard, you configured authentication within the wizard. This authentication policy is bound automatically to the NetScaler Gateway global level. The authentication type that you configure within the NetScaler Gateway wizard is the default authentication type. You can change the default authorization type by running the NetScaler Gateway wizard again or you can modify the global authentication settings in the configuration utility.

If you need to add other authentication types, you can configure authentication policies on NetScaler Gateway and bind the policies to NetScaler Gateway by using the configuration utility. When you configure authentication globally, you define the type of authentication, configure the settings, and set the maximum number of users that can be authenticated.

After configuring and binding the policy, you can set the priority to define which authentication type takes precedence. For example, you configure LDAP and RADIUS authentication policies. If the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

LDAP policy has a priority number of 10 and the RADIUS policy has a priority number of 15, the LDAP policy takes precedence, regardless of where you bind each policy. This is called cascading authentication.

You can select to deliver logon pages from the NetScaler Gateway in-memory cache or from the HTTP server running on NetScaler Gateway. If you choose to deliver the logon page from the in-memory cache, the delivery of the logon page from NetScaler Gateway is faster than from the HTTP server. Choosing to deliver the logon page from the in-memory cache reduces the wait time when many users log on at the same time. You can only configure the delivery of logon pages from the cache as part of a global authentication policy.

You can also configure the network address translation (NAT) IP address that is a specific IP address for authentication. This IP address is unique for authentication and is not the NetScaler Gateway subnet, mapped, or virtual IP addresses. This is an optional setting.

NOTE:

- You cannot use the NetScaler Gateway wizard to configure SAML authentication.
- You can use the Quick Configuration wizard to configure LDAP, RADIUS, and client certificate authentication. When you run the wizard, you can select from an existing LDAP or RADIUS server configured on NetScaler Gateway. You can also configure the settings for LDAP or RADIUS. If you use two-factor authentication, it is recommended that you use LDAP as the primary authentication type.

Configure default global authentication types

1. In the GUI, on the Configuration tab, in the navigation pane, expand **NetScaler Gateway,** and then click **Global Settings**.
2. In the details pane, under Settings, click **Change authentication settings**.
3. In **Maximum Number of Users**, type the number of users who can be authenticated by using this authentication type.
4. In **NAT IP address**, type the unique IP address for authentication.
5. Select **Enable static caching to deliver logon pages faster**.
6. Select **Enable Enhanced Authentication Feedback to provide a message to users if authentication fails**. The message users receive include the password errors, the account disabled or locked, or the user is not found, to name a few.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

7. In **Default Authentication Type**, select the authentication type.
8. Configure the settings for your authentication type, and then click **OK**.

Support to retrieve current login attempts for a user

NetScaler provides an option to retrieve the value of current login attempts for a user by an expression `aaa.user.login_attempts`. This expression takes either one argument (user name) or no argument. If there is no argument, the expression fetches the user name from the `aaa_session` or `aaa_info`.

You can use the `aaa.user.login_attempts` expression with authentication policies for further processing.

To configure the number of login attempts per user

At the command prompt, type:

```
add expression er aaa.user.login_attempts
```

NOTE:

The `aaa.user.login_attempts` expression does not work if the Persistent Login Attempts parameter is enabled. For details about the Persistent Login Attempts parameter, see System user account lockout.

The following CLI examples describe the login attempt configurations for different scenarios:

- Authentication virtual server

  ```
  set authentication vserver av_vs -maxLoginAttempts 5 -failedLoginTimeout 100
  ```

  For details about the authentication virtual server and its supported parameters, see Authentication virtual server.

- NetScaler Gateway virtual server

  ```
  set vpn vserver vpn_vs -maxLoginAttempts 5 -failedLoginTimeout 100
  ```

  For details about a NetScaler Gateway virtual server, see the Virtual servers section.

- Lock out a system user account

  ```
  set aaa parameter -maxloginAttempts 3 -failedLoginTimeout 10
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For details about the system user account lockout, see Lock system user account for management access.

Parameter descriptions:

- `maxLoginAttempts`: Maximum number of login attempts allowed before a user is locked out.
- `failedLoginTimeout`: Number of seconds allowed before the login fails. The user must restart the login process.

Users and groups

After configuring the authentication, authorization, and auditing basic setup, you create users and groups. You first create a user account for each person who authenticates via the NetScaler appliance. If you are using local authentication controlled by the NetScaler appliance itself, you create local user accounts and assign passwords to each of those accounts.

You also create user accounts on the NetScaler appliance if you are using an external authentication server. In this case, however, each user account must exactly match an account for that user on the external authentication server, and you do not assign passwords to the user accounts that you create on the NetScaler. The external authentication server manages the passwords for users that authenticate with the external authentication server.

If you are using an external authentication server, you can still create local user accounts on the NetScaler appliance if, for example, you want to allow temporary users (such as visitors) to log in but do not want to create entries for those users on the authentication server. You assign a password to each local user account, just as you would if you were using local authentication for all user accounts.

Each user account must be bound to policies for authentication and authorization. To simplify this task, you can create one or more groups and assign user accounts to them. You can then bind policies to groups instead of individual user accounts.

Configure policies with groups

After you configure groups, you can use the **Group** dialog box to apply policies and settings that specify user access. If you are using local authentication, you create users and add them to groups that are configured on NetScaler Gateway. The users then inherit the settings for that group.

You can configure the following policies or settings for a group of users in the **Group** dialog box:

- Users

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Authorization policies
- Auditing policies
- Session policies
- Traffic policies
- Bookmarks
- Intranet applications
- Intranet IP addresses

In your configuration, you might have users that belong to more than one group. In addition, each group might have one or more bound session policies, with different parameters configured. Users that belong to more than one group inherit the session policies assigned to all the groups to which the user belongs. To ensure which session policy evaluation takes precedence over the other, you must set the priority of the session policy.

For example, you have group1 that is bound with a session policy configured with the home page www.homepage1.com. Group2 is bound with a session policy configured with home page www.homepage2.com. When these policies are bound to respective groups without a priority number or with a same priority number, the home page that appears to users who belong to both the groups depends on which policy is processed first. By setting a lower priority number, which gives higher precedence, for the session policy with home page www.homepage1.com, you can ensure that users who belong to both the groups receive the home page www.homepage1.com.

If session policies do not have a priority number assigned or have the same priority number, precedence is evaluated in the following order:

- User
- Group
- Virtual server
- Global

If policies are bound to the same level, without a priority number or if the policies have the same priority number, the order of evaluation is per the policy bind order. Policies that are bound first to a level receive precedence over policies bound later.

If we have a user bound to multiple groups with each group having IIP bound, the user can get free IP from any of the bound groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create users and groups

Configure authentication, authorization, and auditing local users by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Users** From NetScaler Gateway, expand **NetScaler Gateway > User Administration**, and then click **AAA Users**.
2. In the details pane, do one of the following:
   - To create a new user account, click **Add**.
   - To modify an existing user account, select the user account, and then click **Open**.
3. In the **Create AAA User** dialog box, in the **User Name** text box, type a name for the user.
4. If creating a locally authenticated user account, clear the **External Authentication** check box and provide a local password that the user uses to log on.
5. Click **Create** or **OK**, and then click **Close**. A message appears in the status bar, stating that the user has been configured successfully.

Configure authentication, authorization, and auditing local groups and add users to them by using the configuration utility

1. Navigate to **Security > AAA - Application Traffic > Groups** From NetScaler Gateway, expand **NetScaler Gateway > User Administration**, and then click **AAA Groups**.
2. In the details pane, do one of the following:
   - To create a new group, click **Add**.
   - To modify an existing group, select the group, and then click **Edit**.
3. If you are creating a new group, in the **Create AAA Group** dialog box, in the **Group Name** text box, type a name for the group.
4. In the **Advanced** area to the right, click **AAA Users**.
   - To add a user to the group, select the user, and then click **Add**.
   - To remove a user from the group, select the user, and then click **Remove**.
   - To create a new user account and add it to the group, click the **Plus** icon, and then follow the instructions in "To configure authentication, authorization, and auditing local users by using the configuration utility."
5. Click **Create** or **OK**. The group that you created appears in the **AAA Groups** page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Delete a group by using the GUI

You can also delete user groups from NetScaler Gateway.

1. Navigate to **Security > AAA - Application Traffic > Groups** From NetScaler Gateway, expandCitrix **Gateway > User Administration,** and then click **AAA Groups**. In the details pane, select the group, and then click Remove.

Configure authentication, authorization, and auditing local users by using the CLI

At the command prompt, type the following commands:

```
add aaa group <groupname>

bind aaa group <groupname> -username <username>
```

Example:

```
add aaa group group-2

bind aaa group group-2 -username user-2
```

Remove users from an authentication, authorization, and auditing group by using the command line interface

At the command prompt, unbind users from the group by typing the following command once for each user account that is bound to the group:

```
unbind aaa group <groupname> -username <username>```
```

Example:

```
unbind aaa group group-hr -username user-hr-1
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Remove an authentication, authorization, and auditing group by using the command line interface

First remove all users from the group. Then, at the command prompt, type the following command to remove a NetScaler AAA group and verify the configuration:

```
rm aaa group <groupname>
```

Example:

```
rm aaa group group-hr
```

NOTE

You cannot add a user name with domain if the user name is already added without domain. If the user name with domain is added first followed by the same user name without domain, then the NetScaler appliance adds the user name to the user list.

The following example shows adding a user name with domain is not permitted if the same user name is added without domain.

```
> add aaa user u47985

Done

> show aaa users

1)   UserName: u47985

Done

> add aaa user u47985@domain.com

ERROR: User already exists
```

The following example shows if the user name with domain is added first followed by the same user name without domain, then the NetScaler appliance adds the user name to the user list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
> add aaa user u47985@domain.com

Done

> add aaa user u47985

Done

> sh aaa user

1)   UserName: u47985@domain.com

2)   UserName: u47985
```

Authentication methods

The NetScaler appliance can authenticate users with local user accounts or by using an external authentication server. The appliance supports the following authentication types:

- **LOCAL:** Authenticates to the NetScaler appliance by using a password, without reference to an external authentication server. User data is stored locally on the NetScaler appliance.
- **RADIUS:** Authenticate to an external RADIUS server.
- **LDAP:** Authenticates to an external LDAP authentication server.
- **TACACS:** Authenticates to an external Terminal Access Controller Access-Control System (TACACS) authentication server.
- **CERT:** Authenticates to the NetScaler appliance by using a client certificate, without reference to an external authentication server.
- **NEGOTIATE:** Authenticates to a Kerberos authentication server. If there is an error in Kerberos authentication, NetScaler uses NTLM authentication.
- **SAML:** Authenticates to a server that supports the Security Assertion Markup Language (SAML).
- **SAML IDP:** Configures the NetScaler to serve as a Security Assertion Markup Language (SAML) Identity Provider (IdP).
- **WEB:** Authenticates to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that the user authentication was successful.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Native OTP:** NetScaler appliance supports one-time passwords (OTPs) without having to use a third-party server.
- **Push notification:** NetScaler Gateway supports push notifications for OTP. Users do not have to manually enter the OTP received on their registered devices to log in to NetScaler Gateway. Admins can configure NetScaler Gateway such that login notifications are sent to users' registered devices using push notification services.
- **Email OTP:** The Email OTP method enables you to authenticate using the one-time password (OTP) that is sent to the registered email address. When you try to authenticate on any service, the server sends an OTP to the registered email address of the user.
- **reCaptcha authentication** - NetScaler Gateway supports a new first class action 'captchaAction' that simplifies reCaptcha configuration. As reCaptcha is a first class action, it can be a factor of its own. You can inject reCaptcha anywhere in the nFactor flow.
- **nFactor authentication:** Multifactor authentication enhances the security of an application by requiring users to provide multiple proofs of identity to gain access. The NetScaler appliance provides an extensible and flexible approach to configuring multifactor authentication. This approach is called nFactor authentication.
- **OAuth authentication:** OAuth authentication authorizes and authenticates users to services that are hosted on applications such as Google, Facebook, and Twitter.

nFactor authentication

IMPORTANT

- nFactor authentication is supported from NetScaler 11.0 Build 62.x onwards.
- For nFactor authentication to work with NetScaler, an Advanced license or a Premium license is required.
- Starting from release 13.0 build 67.x, nFactor authentication is supported with Standard license only for Gateway/VPN virtual server. For more information about nFactor authentication with NetScaler Gateway, see nFactor for Gateway Authentication.

Multifactor authentication enhances the security of an application by requiring users to provide multiple proofs of identity to gain access. NetScaler provides an extensible and flexible approach to configuring multifactor authentication. This approach is called *nFactor authentication*.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

How nFactor authentication works

Each authentication factor performs the following tasks:

- Collects credentials from the user. NetScaler supported authentication mechanisms include LDAP, RADIUS, SAML assertion, Client Certificate, OAuth OpenID Connect, Kerberos, and so on.
- Evaluates the supplied credentials to decide whether the authentication succeeded, failed or the actions like Group extraction, Attribute extraction is to be performed.
- Based on the evaluation results, access is either granted, denied, or a next factor is selected.
- Repeat these steps, until there are no more next factors to evaluate.

With nFactor authentication you can:

- Configure any number of authentication factors.
- Select the next factor based on the result of the previous factor.
- Customize the login interface. For example, you can customize the label names, error messages, and help text.
- Extract user group information without doing authentication.
- Configure a pass-through for an authentication factor. This means that no explicit login interaction is required for that factor.
- Configure the order in which different types of authentication are applied. Any supported authentication mechanism on NetScaler can be configured as a factor in the nFactor authentication setup. These factors run in the order in which they are configured.
- Configure NetScaler to proceed to the next required authentication factor when authentication fails. To do so, you configure another authentication policy with the same condition, but with the next highest priority and with the action set to "NO_AUTH". You must configure the next factor, which must specify the alternative authentication mechanism to apply.

Encryption of NetScaler Gateway login information for nFactor authentication

NetScaler Gateway with nFactor authentication can encrypt the login request fields submitted by a client (browser or SSO apps) during the authentication process. The encrypted login request fields provide an extra layer of security to protect the user’s sensitive data from being disclosed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Compatible browsers

The following table lists the browsers along with version details that support login encryption.

BROWSERS	VERSION
Chrome	78 and above
Firefox	69 and above
Edge	42 and above
Safari	11.0 and above
Opera	66

Compatible clients

The following section lists the clients along with version details that support encryption of NetScaler Gateway login information.

- Citrix Workspace app in Mac supports encryption only when OS version is 10.14.x and above.
- Citrix SSO app in Mac supports encryption only when OS version is 10.14.x and above.
- Windows SSO app does not have restrictions on the compatibility.

To enable the login encryption by using the CLI

At the command prompt, type:

```
set aaa parameter [-loginEncryption (ENABLED | DISABLED)]
```

NOTE

- The loginEncryption parameter is DISABLED by default. You must ENABLE it.
- Policy expressions that rely on the post body containing encrypted login data are not supported because policy evaluation occurs before the login payload is decrypted.

To enable the login encryption by using the GUI

1. Navigate to **Security > AAA – Application Traffic**, click **Change authentication AAA settings** under **Authentication Settings** section.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. On the **Configure AAA Parameter** page, scroll down to the **Login Encryption** option, and enable it.

IMPORTANT NOTE ABOUT LOGIN ENCRYPTION:

When you try logging on to NetScaler Gateway, you see an error message that the password encryption has failed and that you must disable password encryption to continue with the logon, in the following scenarios:

- Login encryption is enabled.
- An unsupported browser is used.

You can ignore the suggestion to disable login encryption. But, ensure that you use a supported browser for a successful logon.

nFactor concepts, entities, and terminology

This topic captures some of the major entities involved in nFactor authentication and their significance.

Login schema

nFactor decouples the 'view', the user interface, with the 'model' that is the runtime handling. nFactor's view is defined by the login schema. Login schema is an entity that defines what the user sees and specifies how to extract the data from the user.

For defining a view, the login schema points to a file on disk that defines the logon form. This file must be according to the specification of the "Citrix® Common Forms Protocol." This file is essentially an XML definition of the logon form.

In addition to the XML file, the login schema contains advanced policy expressions to glean user name and password from the user's login request. These expressions are optional, and can be omitted if user name and password from user arrive with expected form variable names.

Login schema also defines, whether the current set of credentials must be used as default SingleSignOn credentials.

Login schema can be created by running the following CLI command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication loginSchema <name> -authenticationSchema <string> [-
userExpression <string>] [-passwdExpression <string>] [-
userCredentialIndex <positive_integer>] [-passwordCredentialIndex
<positive_integer>] [-authenticationStrength <positive_integer>] [-
SSOCredentials ( YES | NO )]
```

NOTE:

- `SSOCredentials` indicate whether the current factor credentials are the default SSO credentials. Default value is NO.
- By default, the last factor's credentials are used for SSO in nFactor authentication. However, by configuring `SSOCredentials`, you can opt to use the current factor's credentials. If `SSOCredentials` is configured in multiple factors, the final factor with this setting takes precedence.
- For nFactor authentication, we recommend enabling `SSOCredentials` only on the factor that actually validates user credentials (like a password), and not on factors that gather user information or metadata.

  For example, if your nFactor flow first collects user attributes (such as group membership) and a later factor verifies the password, make sure `SSOCredentials` is enabled only on that password verification factor.

For details about each parameter, see authentication-loginSchema.

Policy label

A policy label is a collection of policies. It is a construct not alien to NetScaler's policy infrastructure. Policy label defines an authentication factor. That is, it contains all the policies necessary to determine whether credentials from the user are satisfied. All the policies in a policy label can be assumed as homogenous. Policy label for authentication cannot take policies of different type, say rewrite. To put in a different way, all the policies in a policy label validate the same password/credential from the user, mostly. The result of policies in a policyLabel follows the logical OR condition. Hence, if the authentication specified by the first policy succeeds, other policies following it are skipped.

Policy label can be created by running the following CLI command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication policy label mylabel –loginSchema <>
```

A policy label takes the login schema as the property. Login schema defines the view for that policy label. If the login schema is not specified, an implicit login schema, LSCHEMA_INT, is associated with that policy label. Login schema decides whether a policy label becomes a passthrough or not.

Virtual server label

In NetScaler's advanced policy infrastructure, a virtual server is also an implicit policy label. That's because the virtual server can also be bound with more than one policy. However, a virtual server is special because it is the entry point for client traffic and can take policies of a different type. Each of the policies it put under its own label within the virtual server. Hence, the virtual server is a conglomeration of labels.

Next factor

Whenever a policy is bound to a virtual server or a policy label, it can be specified with the next factor. Next factor determines what must be done if a given authentication succeeds. If there is no next factor, that concludes the authentication process for that user.

Each policy bound to a virtual server or policy label can have a different next factor. This allows for ultimate flexibility where in every policy's success can define a new path for user's authentication. Administrator can take advantage of this fact and craft clever fallback factors for users who do not meet certain policies.

No-Auth policy

nFactor introduces a special built-in policy called NO_AUTHN. NO_AUTHN policy always returns success as the authentication result. The `No-auth` policy can be created by running the following CLI command:

```
add authentication policy noauthpolicy –rule <> -action NO_AUTHN
```

As per the command, the `no-authentication` policy takes a rule that can be any advanced policy expression. Authentication result is always success from NO_AUTHN.

A `no-auth` policy in itself does not seem to add value. However, when used along with passthrough policy labels, it offers great flexibility to make logical decisions to drive user authentication flow. NO_AUTHN policy and passthrough factors offer a new dimension to nFactor's flexibility.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Note: Check the examples that depict the usage of `no-auth` and passthrough in subsequent sections.

Passthrough factor/label

Once the user has passed the authentication at the virtual server (for the first factor), subsequent authentications happen at policy labels or user defined (secondary) factors. Every policy label/ factor is associated with a login schema entity to display the view for that factor. This allows for customizing views based on the path the user would have taken to arrive at a given factor.

There are specialized kinds of policy labels which do not point explicitly to a login schema. Specialized policy labels point to a login schema that does not actually point to the XML file for the view. These policy labels/factors are called 'passthrough' factors.

Passthrough factors can be created by running the following CLI commands:

Example 1:

```
add authentication policylabel example1
```

Example 2:

```
add loginschema passthrough_schema –authenticationSchema noschema

add authentication policylabel example2 –loginschema passthrough_schema
```

Passthrough factor implies that the authentication, authorization, and auditing subsystem must not go back to the user to get the credential set for that factor. Instead, it is a hint for authentication, authorization, and auditing to continue with already obtained credentials. This is useful in cases where user intervention is not desired. For example,

- When the user is presented two password fields, after the first factor, the second factor does not need user intervention.
- When authentication of a type (say certificate) is done, and the administrator must extract groups for that user.

Passthrough factor can be used with `NO_AUTH` policy to make conditional jumps.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

nFactor authentication flow

Authentication always begins at the virtual server in nFactor. Virtual server defines the first factor for the user. The first form that the user sees is served by the virtual server. The logon form that the user sees can be customized at the virtual server using login schema policies. If there are no login schema policies, a single user name and password field are displayed to the user.

If more than one password fields must be displayed to the user on customized form, login schema policies must be used. They allow for displaying different forms based on the configured rules (such as intranet user versus external user, service provider A versus service provider B).

Once user credentials are posted, authentication begins at the authentication virtual server, the first factor. Because the authentication virtual server can be configured with multiple policies, each of them is evaluated in a sequence. At any given point, if an authentication policy succeeds, the next factor specified against it is taken. If there is no next factor, the authentication process ends. If the next factor exists, it is checked if that factor is a passthrough factor or a regular factor. If that is passthrough, authentication policies on that factor are evaluated without user intervention. Otherwise, the login schema associated with that factor is displayed to the user.

Example of using passthrough factor and no-auth policies to make logical decisions

Administrator would like to decide nextFactor based on groups.

```
add authentication policylabel group check

add authentication policy admingroup –rule
http.req.user.is_member_of("Administrators") –action NO_AUTHN

add authentication policy nonadmins –rule true –action NO_AUTHN

bind authentication policy label group check –policy admingroup –pri 1 –
nextFactor factor-for-admin

bind authentication policy label groupcheck –policy nonadmins –pri 10 –
nextfactor factor-for-others
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication policy first_factor_policy –rule <> -action <>

bind authentication vserver <> -policy first_factor_policy –priority 10 –
nextFactor groupcheck
```

Configuring nFactor authentication

You can configure multiple authentication factors using the nFactor configuration. The nFactor configuration is supported only in NetScaler Advanced and Premium editions.

Methods to configure nFactor

You can configure nFactor authentication by one of the following methods:

- **nFactor Visualizer:** nFactor visualizer enables you to easily link factors or policy labels together in a single pane and also change the linking of the factors in the same pane. You can create an nFactor flow using the visualizer and bind that flow to an authentication, authorization, and auditing virtual server. For details about nFactor Visualizer and an example nFactor configuration using the visualizer, see nFactor Visualizer for simplified configuration.
- **NetScaler GUI:** For details, see section **Configuration elements involved in nFactor configuration**.
- **NetScaler CLI:** For a sample snippet on nFactor configuration using the NetScaler CLI, see Sample snippet on nFactor configuration by using the NetScaler CLI.

IMPORTANT:

This topic contains details about configuring nFactor by using the NetScaler GUI.

Configuration elements involved in nFactor configuration

The following elements are involved in configuring nFactor. For detailed steps, refer to the appropriate sections in this topic.

CONFIGURATION ELEMENT	TASKS TO BE PERFORMED
AAA virtual server	Create a AAA virtual server
	Bind portal theme to AAA virtual server

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CONFIGURATION ELEMENT	TASKS TO BE PERFORMED
	Enable client certificate authentication
Login schema	Configure a login schema profile
	Create and bind a login schema policy
Advanced authentication policies	Create advanced authentication policies
	Bind first factor advanced authentication policy to NetScaler AAA virtual server
	Use extracted LDAP groups to select the next authentication Factor
Authentication policy label	Create authentication policy label
	Bind authentication policy label
nFactor for NetScaler Gateway	Create authentication profile to link a NetScaler AAA virtual server with NetScaler Gateway virtual server
	Configure SSL parameters and CA certificate for NetScaler Gateway
	Configure NetScaler Gateway traffic policy for nFactor single sign-on to StoreFront

How nFactor works

When a user connects to the authentication, authorization, and auditing or NetScaler Gateway virtual server, the sequence of events that occur are as follows:

1. If forms-based authentication is used, the login schema bound to the authentication, authorization, and auditing virtual server is displayed.
2. Advanced authentication policies bound to the authentication, authorization, and auditing virtual server are evaluated.
    - If the advanced authentication policy succeeds, and if the next factor (authentication policy label) is configured, the next factor is evaluated. If Next Factor is not configured, then authentication is complete and successful.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- If the advanced authentication policy fails, and if Goto Expression is set to Next, then the next bound advanced authentication policy is evaluated. If none of the advanced authentication policies succeed, then authentication fails.

3. If the next factor authentication policy label has a Login Schema bound to it, it is displayed to the user.
4. The advanced authentication policies bound to the next factor authentication policy label are evaluated.
    - If the Advanced authentication policy succeeds, and if the next factor (authentication policy label) is configured, the next factor is evaluated.
    - If Next Factor is not configured, then authentication is complete and successful.
5. If the Advanced authentication policy fails, and if Goto Expression is Next, then the next bound advanced authentication policy is evaluated.
6. If the policies succeed, then authentication fails.

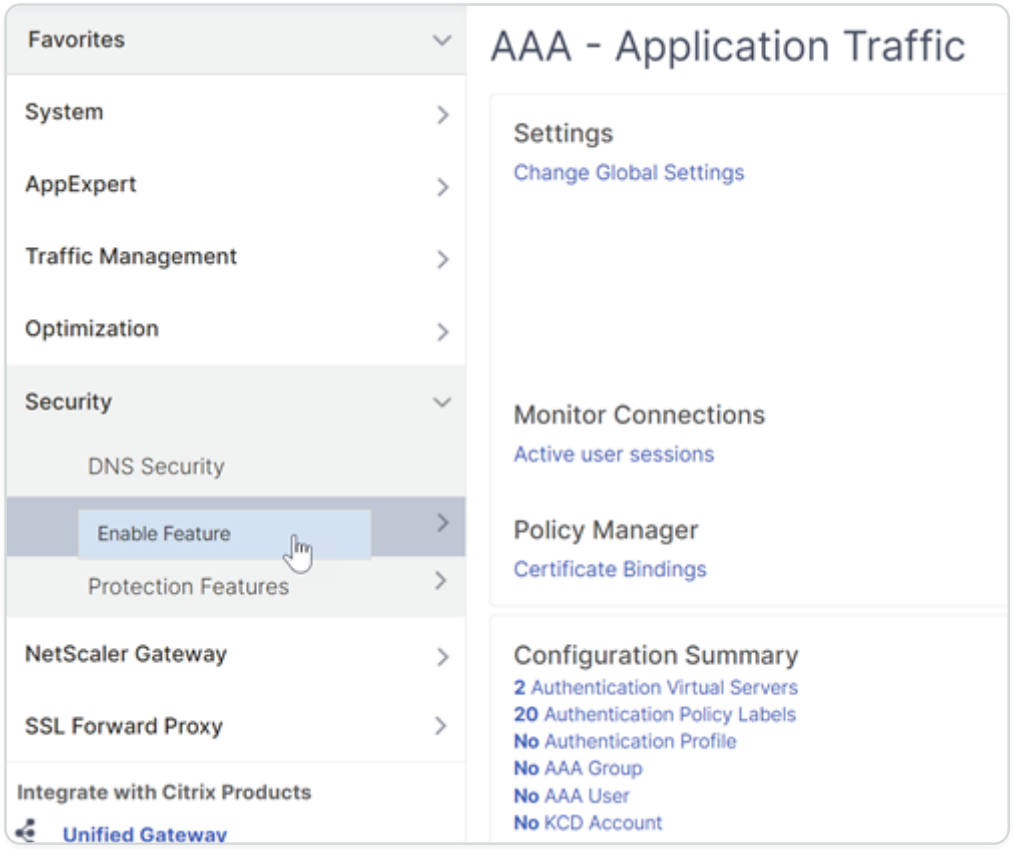
Authentication, authorization, and auditing virtual server

To use nFactor with NetScaler Gateway, you first configure it on an authentication, authorization, and auditing virtual server. Then you later link the authentication, authorization, and auditing virtual server to the NetScaler Gateway virtual server.

Create authentication, authorization, and auditing Virtual Server

1. If the Authentication, authorization, and auditing feature is not already enabled, navigate to, **Security > AAA – Application Traffic**, and right-click to enable the feature.

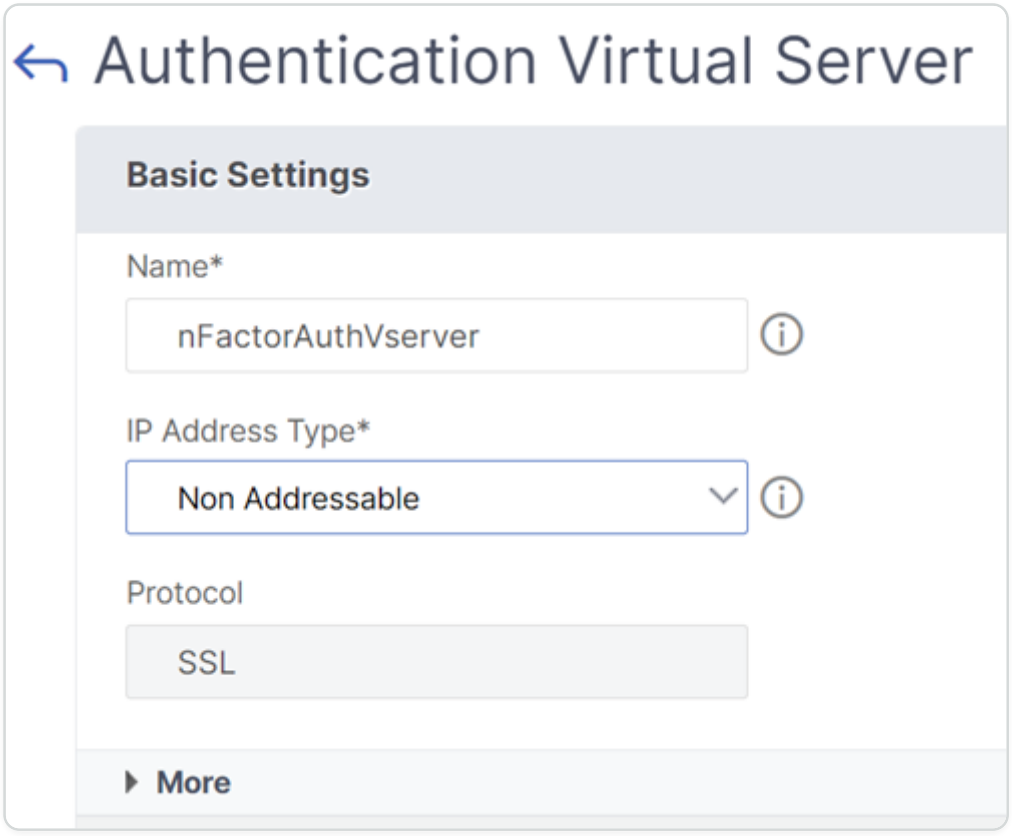
© 1997–2026 Citrix Systems, Inc. All rights reserved.



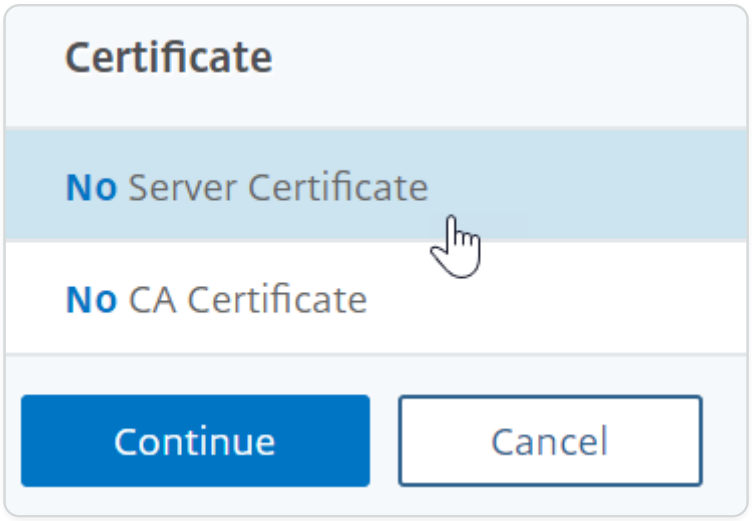
2. Navigate to **Configuration > Security > AAA - Application Traffic > Virtual Servers**.
3. Click **Add** to create an authentication virtual server.
4. Enter the following information and click **OK**.

PARAMETER NAME	PARAMETER DESCRIPTION
Name	Name for the authentication, authorization, and auditing virtual server.
IP address Type	Change the IP address Type to **Non Addressable** if this virtual server is used only for NetScaler Gateway.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

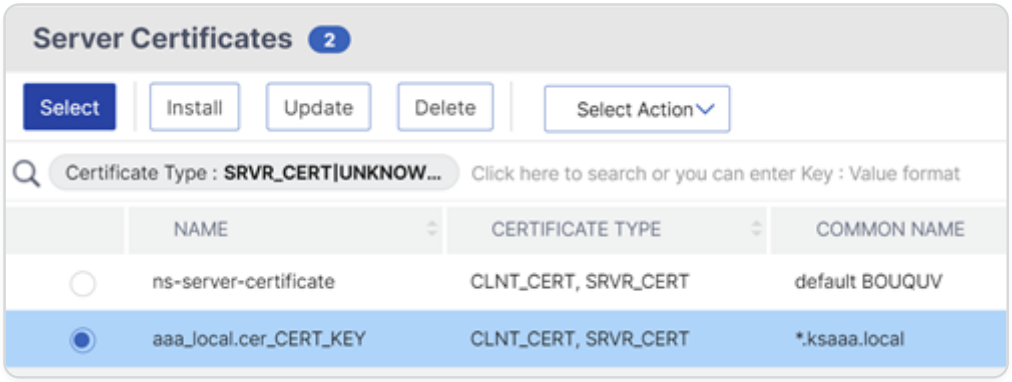


5. Under Certificate, select **No Server Certificate**.

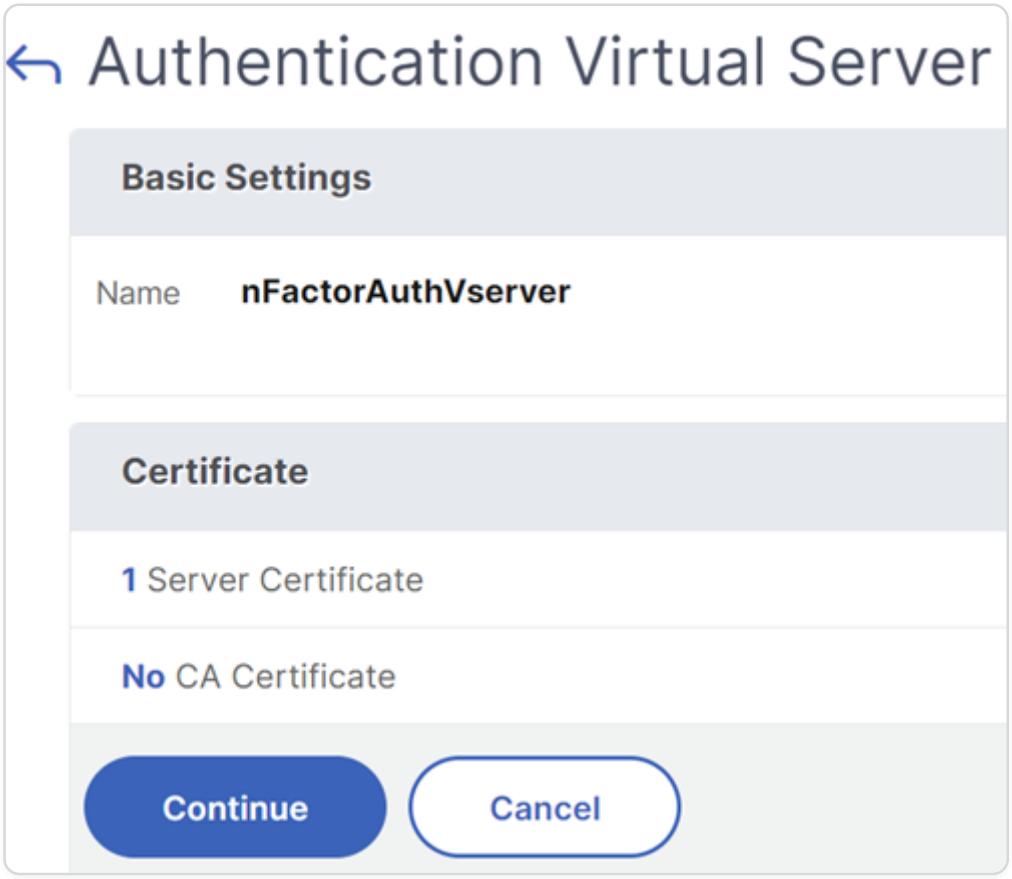


6. Click the text, **Click to select** to select the server certificate.
7. Click the radio button next to a certificate for the authentication, authorization, and auditing Virtual Server, and click **Select**. The chosen certificate doesn't matter because this server is not directly accessible.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

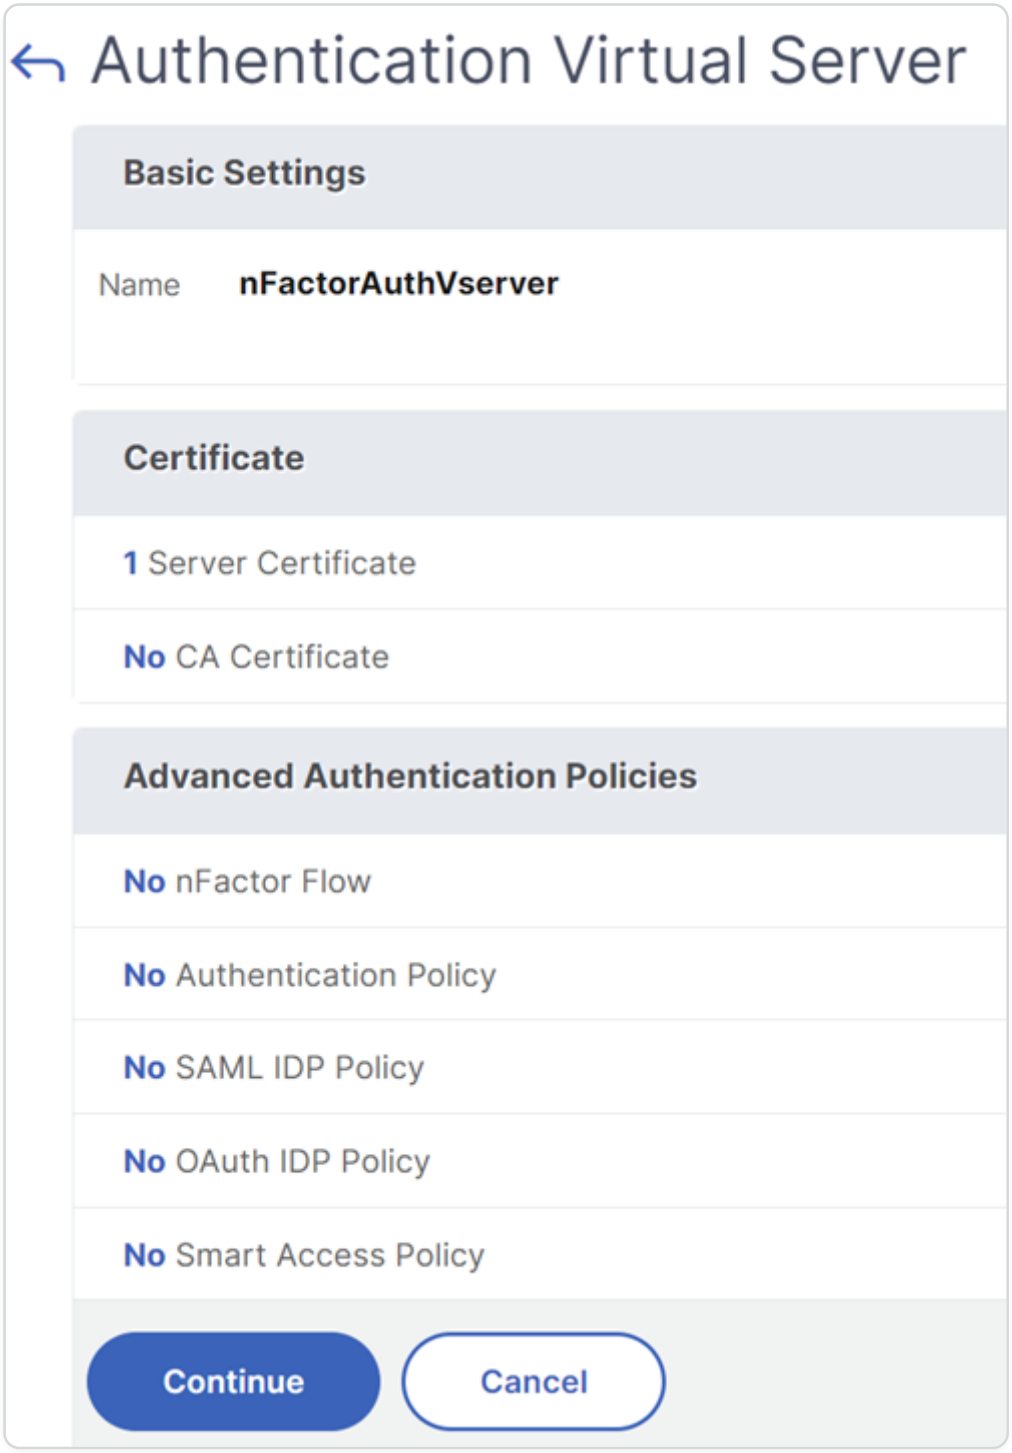


8. Click **Bind**.
9. Click **Continue** to close the **Certificate** section.



10. Click **Continue**.

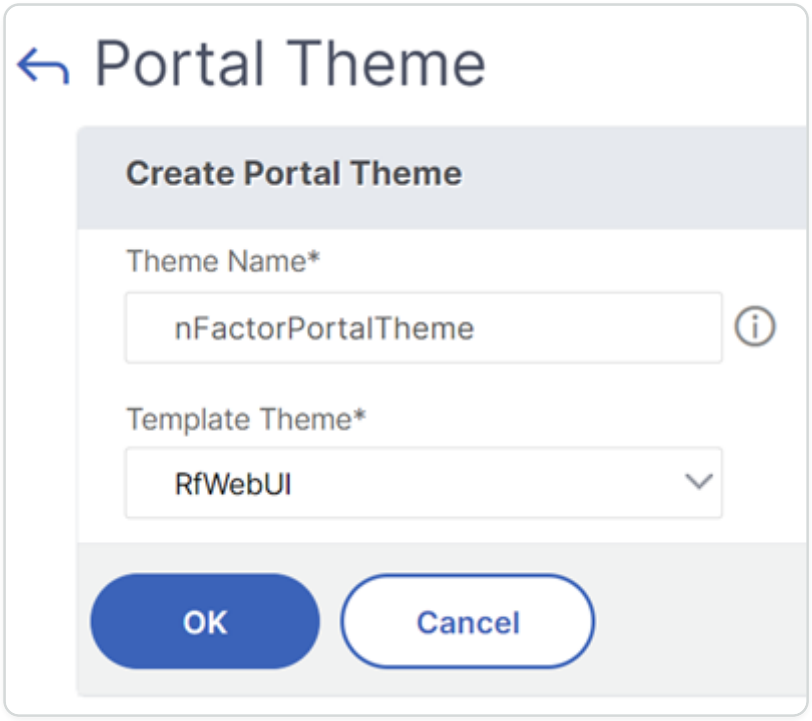
© 1997–2026 Citrix Systems, Inc. All rights reserved.



Bind the portal theme to the authentication, authorization, and auditing virtual server

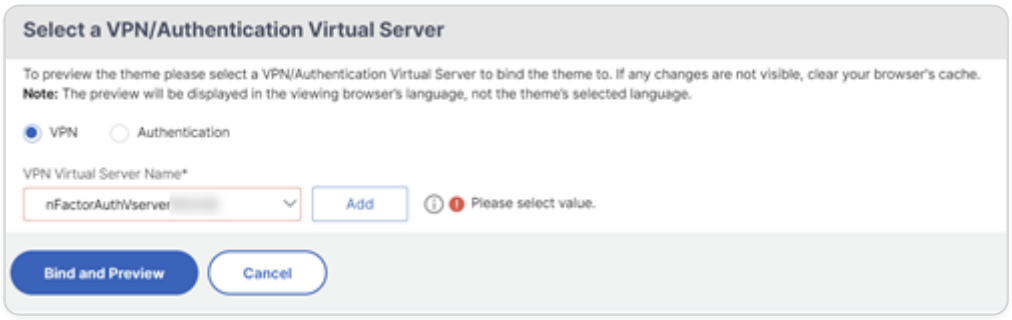
1. Navigate to **NetScaler Gateway > Portal Themes**, and add a theme. You create the theme under NetScaler Gateway, and then later bind it to the authentication, authorization, and auditing virtual server.
2. Create a theme based on the RfWebUI template theme.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



3. After adjusting the theme as desired, at the top of the portal theme editing page, click **Click to Bind and View Configured Theme**.

4. Change the selection to Authentication. From the **Authentication Virtual Server Name** drop-down menu, select the authentication, authorization, and auditing virtual server, and click **Bind and Preview** and close the preview window.

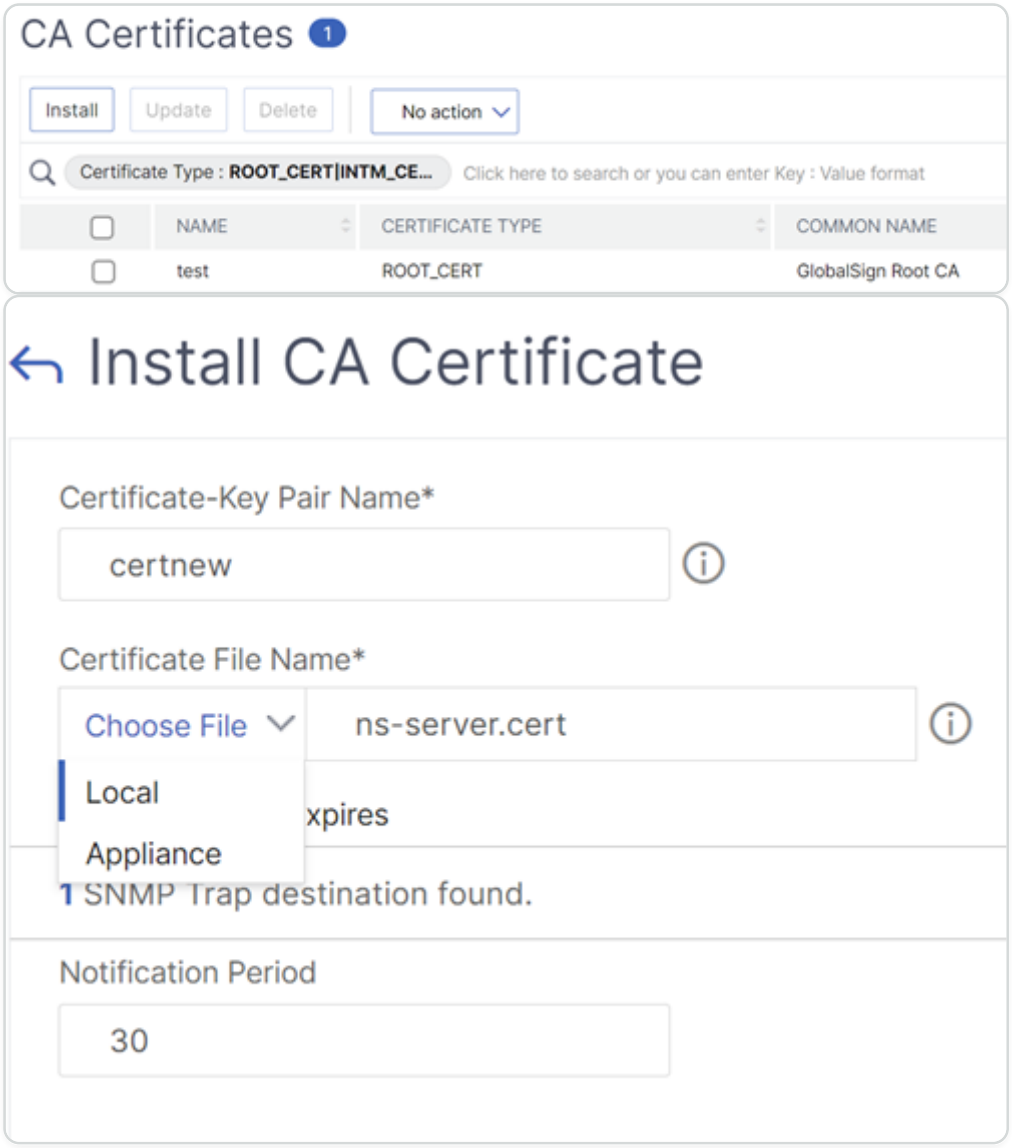


Enable the client certificate authentication

If one of your authentication factors is the client certificate, then you must perform some SSL configuration on the authentication, authorization, and auditing virtual server:

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**, and install the root certificate for the issuer of the client certificates. Root certificates do not have a key file.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. Navigate to **Traffic Management > SSL > Change advanced SSL settings**.

   a. Scroll down to check whether **Default Profile** is **ENABLED**. If yes, then you must use an SSL Profile to enable Client Certificate Authentication. Otherwise, you can enable Client Certificate Authentication directly on the authentication, authorization, and auditing virtual server in the SSL Parameters section.

3. If default SSL Profiles are not enabled:

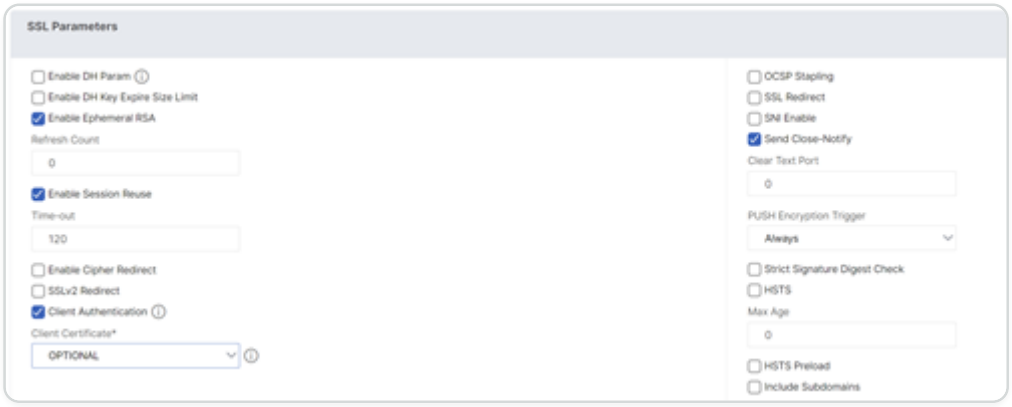
© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Navigate to **Security > AAA - Application > Virtual Servers**, and edit an existing authentication, authorization, and auditing virtual server.

b. In the **SSL Parameters** section, click the pencil icon.

a. Enable the **Client Authentication** option.

b. Set **Client Certificate** to **Optional** and click **OK**.



4. If Default SSL Profiles are enabled, then create an SSL Profile with Client Authentication enabled:

a. On the left menu, expand System, and click Profiles.

b. On the top right, switch to the SSL Profile tab.

c. Right-click the ns_default_ssl_profile_frontend profile, and click Add. This copies settings from the default profile.

d. Give the Profile a name. The purpose of this profile is to enable Client Certificates.

e. Scroll down and find the Client Authentication check box. Check the box.

f. Change the Client Certificate drop-down menu to OPTIONAL.

g. Copying the default SSL Profile does not copy the SSL Ciphers. You must redo them.

h. Click Done when done creating the SSL Profile.

i. Navigate to **Security > AAA – Application Traffic > Virtual Servers**, and edit an authentication, authorization, and auditing virtual server.

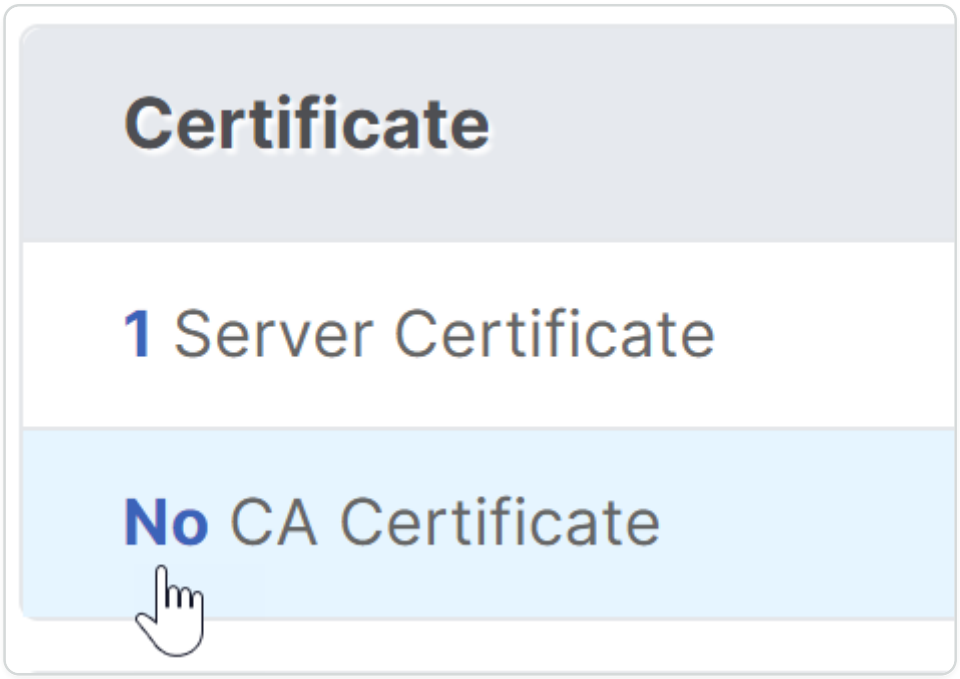
j. Scroll down to the SSL Profile section and click the pencil.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

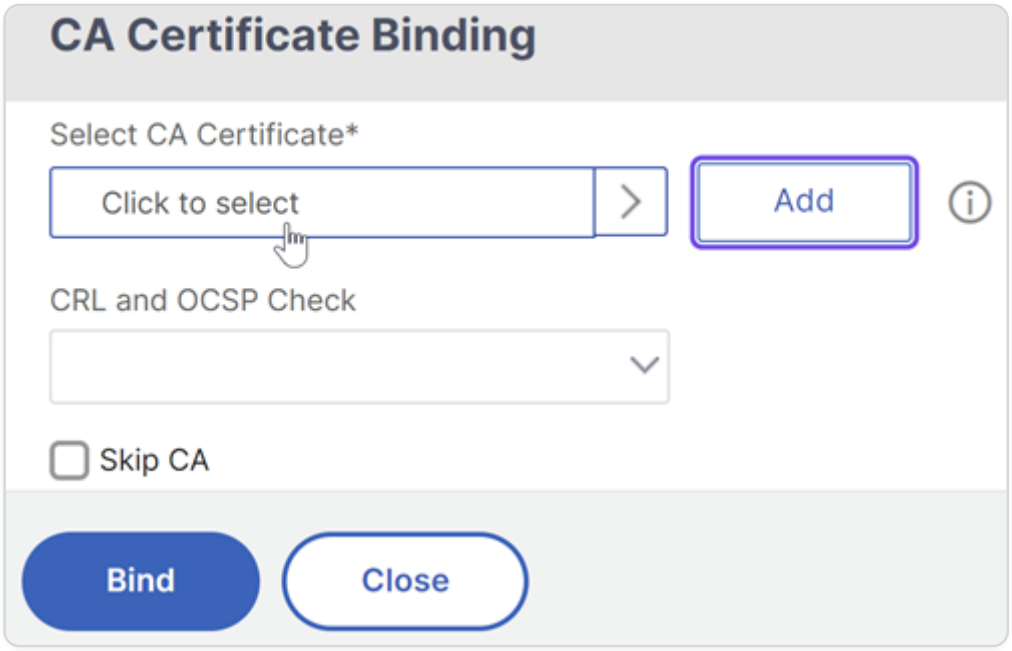
k. Change the SSL Profile drop-down menu to the profile that has Client Certificates enabled. Click OK.

l. Scroll down this article until you reach the instructions to bind the CA certificate.

5. On the left, in the **Certificate** section, click **No CA Certificate**.

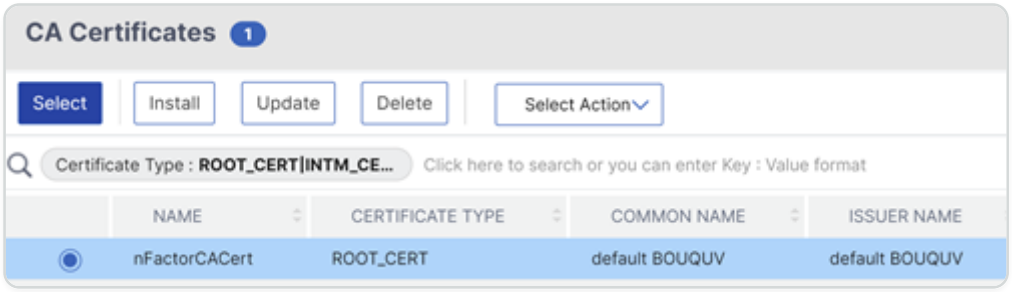


6. Click the text, **Click to select**.

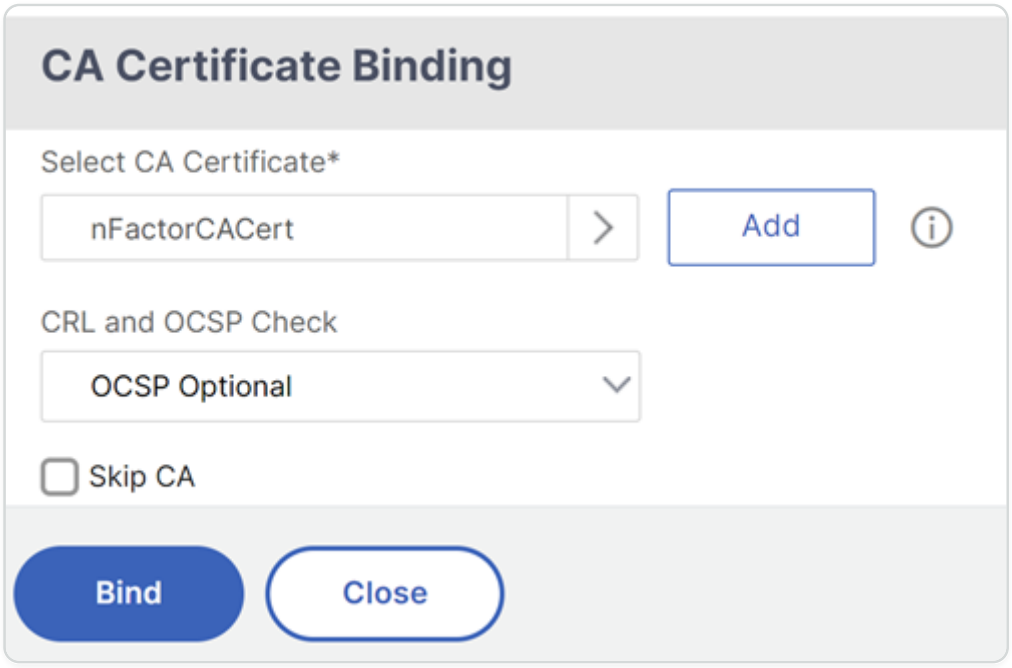


7. Click the radio button next to the root certificate for the issuer of the client certificates, and click **Select**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



8. Click **Bind**.



Login schema XML file

Login Schema is an XML file providing the structure of forms-based authentication logon pages.

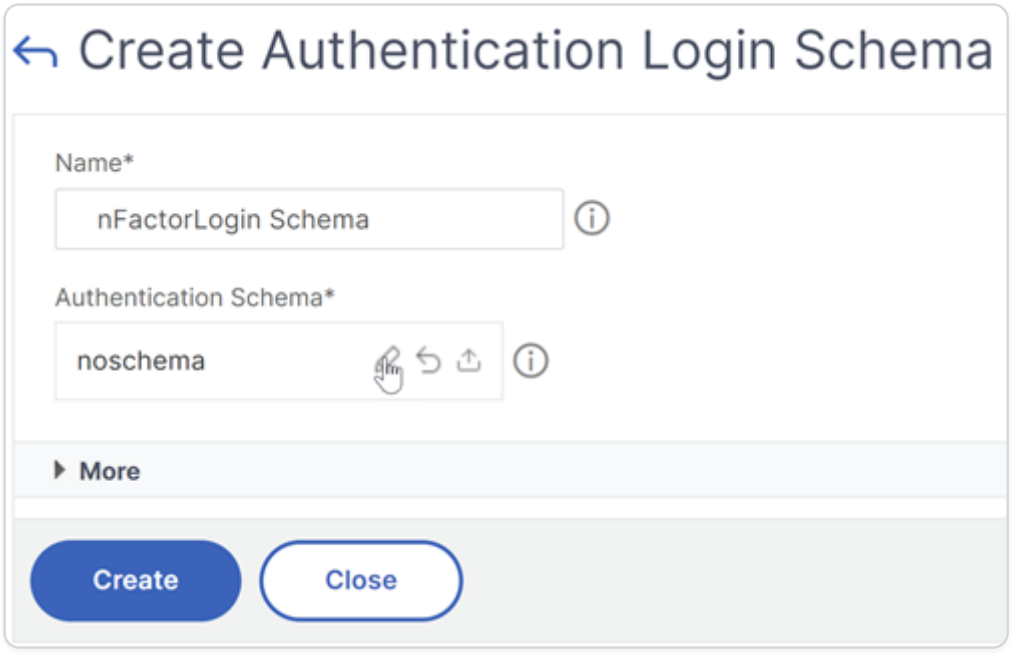
nFactor implies multiple authentication factors that are chained together. Each Factor can have different Login Schema pages/files. In some authentication scenarios, users can be presented with multiple logon screens.

Configure a login schema profile

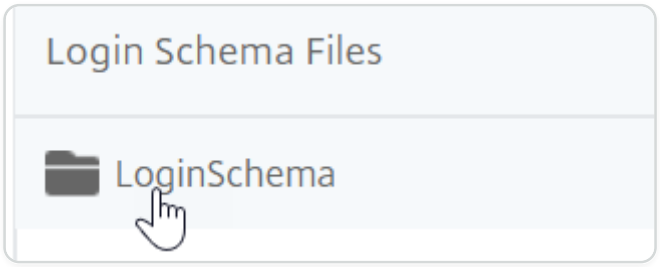
To configure a Login Schema Profile:

1. Create or Edit a Login Schema .XML file based on your nFactor design.
2. Navigate to **Security > AAA - Application Traffic > Login Schema**.
3. On the right, switch to the **Profiles** tab, and click **Add**.
4. In the **Authentication Schema** field, click the pencil icon.

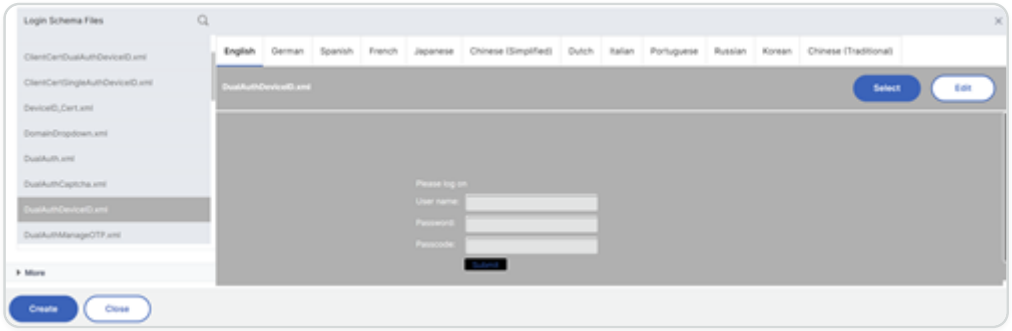
© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Click the **LoginSchema** folder to see the files in it.



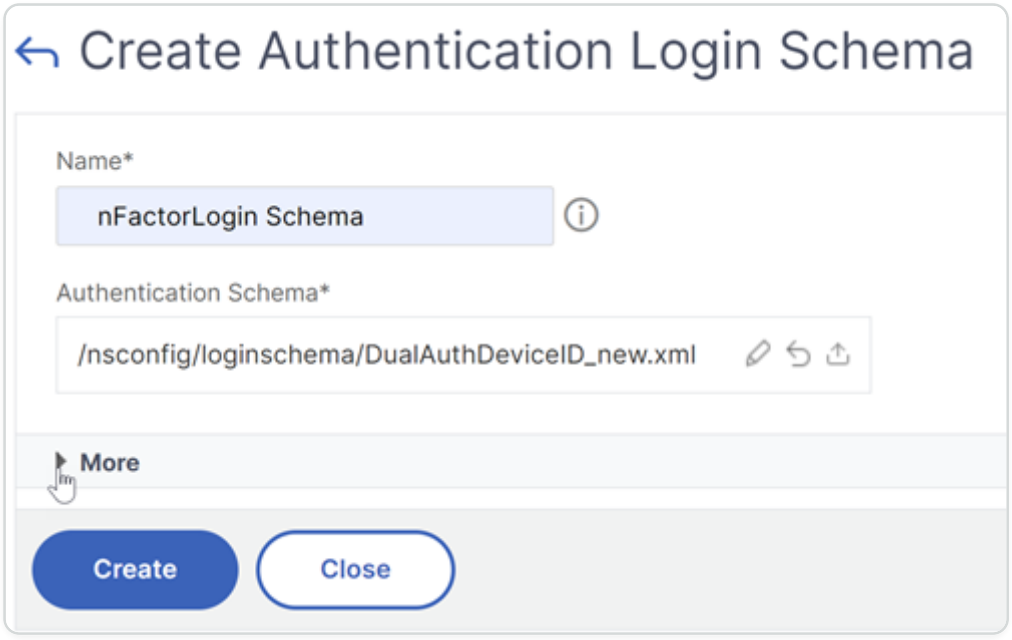
6. Select one of the files. You can see a preview on the right. The labels can be changed by clicking the **Edit** button on the top right.



7. When you Save the changes, a new file is created under /nsconfig/LoginSchema.
8. On the top right, click **Select**.

9. Give the Login Schema a name, and click **More**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

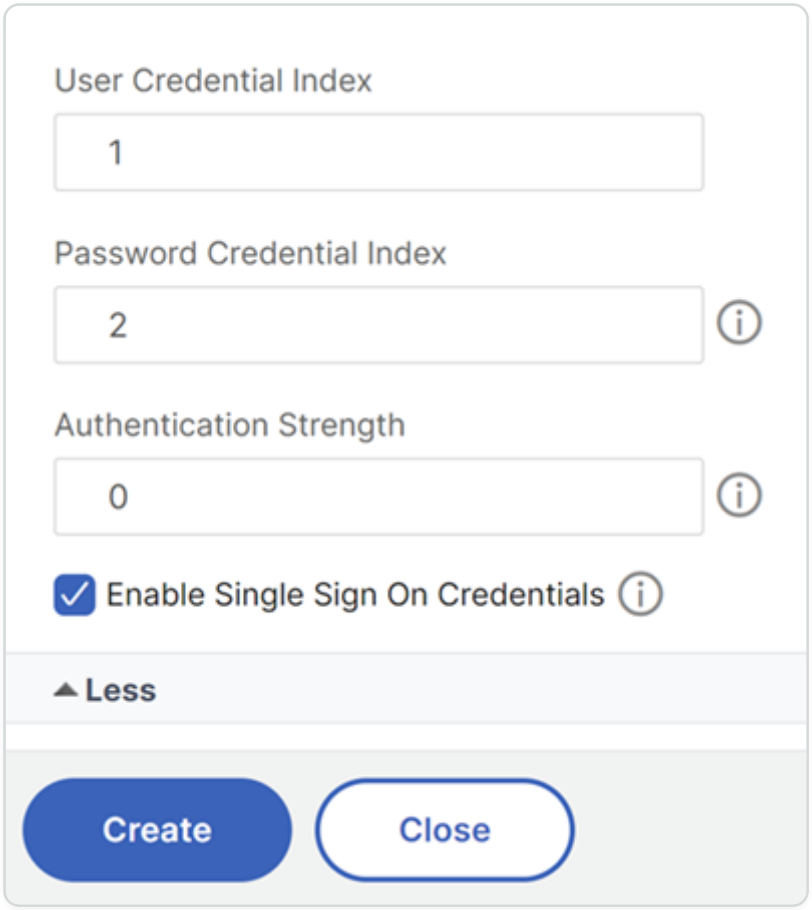


10. Use the user name and the password entered in the login schema for single sign-on (SSO) to a back-end service, for example StoreFront.

    You can use the credentials entered in the login schema as your Single Sign-On credentials by using any of the following methods.

    - Click **More** at the bottom of the **Create Authentication Login Schema** page and select **Enable Single Sign On Credentials**.
    - Click **More** at the bottom of the **Create Authentication Login Schema** page and enter unique values for the user credential index and password credential index. These values can be between 1 and 16. Later you reference these index values in a traffic policy/profile by using the expression AAA.USER.ATTRIBUTE(#).

© 1997–2026 Citrix Systems, Inc. All rights reserved.



11. Click **Create** to create the login schema profile.

NOTE:

If you edit the login schema file (.xml) later, for changes to be reflected you must edit the login schema profile and select the login schema (.xml) file again.

Create and bind a login schema policy

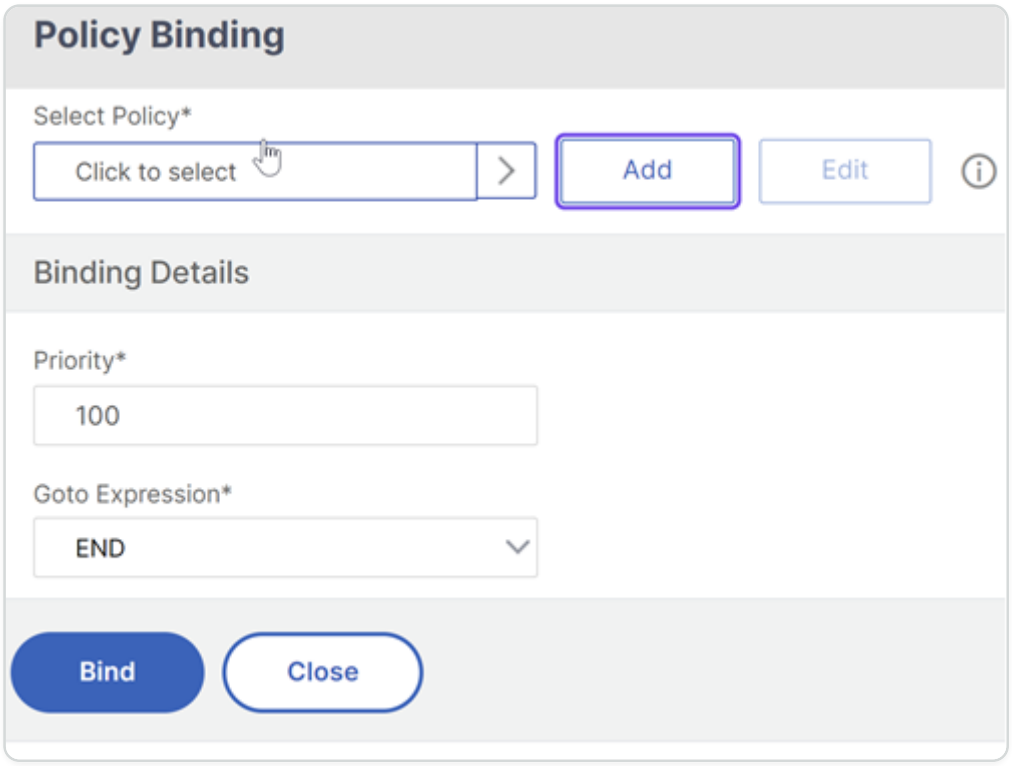
To bind a login schema profile to an authentication, authorization, and auditing virtual server, you must first create a login schema policy. Login schema policies are not required when binding the login schema profile to an authentication policy label, as detailed later.

To create and bind a login schema policy:

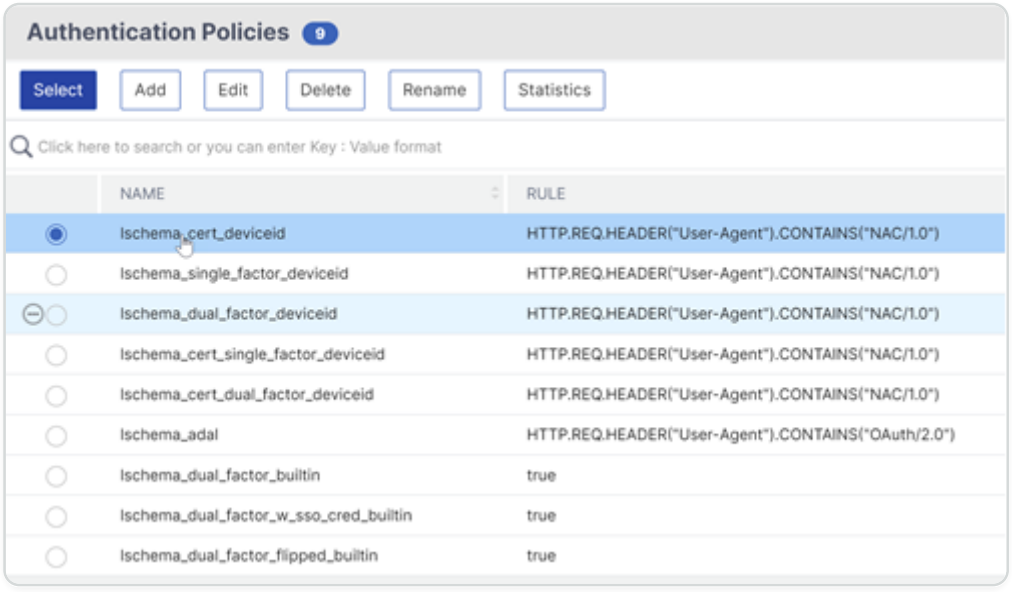
1. Navigate to **Security > AAA - Application Traffic > Login Schema**.
2. On the **Policies** tab, click **Add**.
3. Use the **Profile** drop-down menu to select the Login Schema Profile you already created.
4. Enter an advanced policy expression in the **Rule** box, and click **Create**.
5. Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and click edit to an existing authentication, authorization, and auditing virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. In the Advanced Settings column, click **Login Schemas**.
7. In the Login Schemas section, click **No Login Schema**.
8. Select an authentication policy from the **Select Policy** drop-down list.



9. On the **Authentication Policies** page, click the radio button next to the authentication policy, and click **Select**. Only login schema policies appear in this list. Login schema profiles (without a policy) do not appear.



10. Click **Bind**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Advanced authentication policies

Authentication policies are a combination of policy expression, and policy action. If the expression is true, then evaluate the authentication action.

Create advanced authentication policies

Authentication policies are a combination of policy expression and policy action. If the expression is true, then evaluate the authentication action.

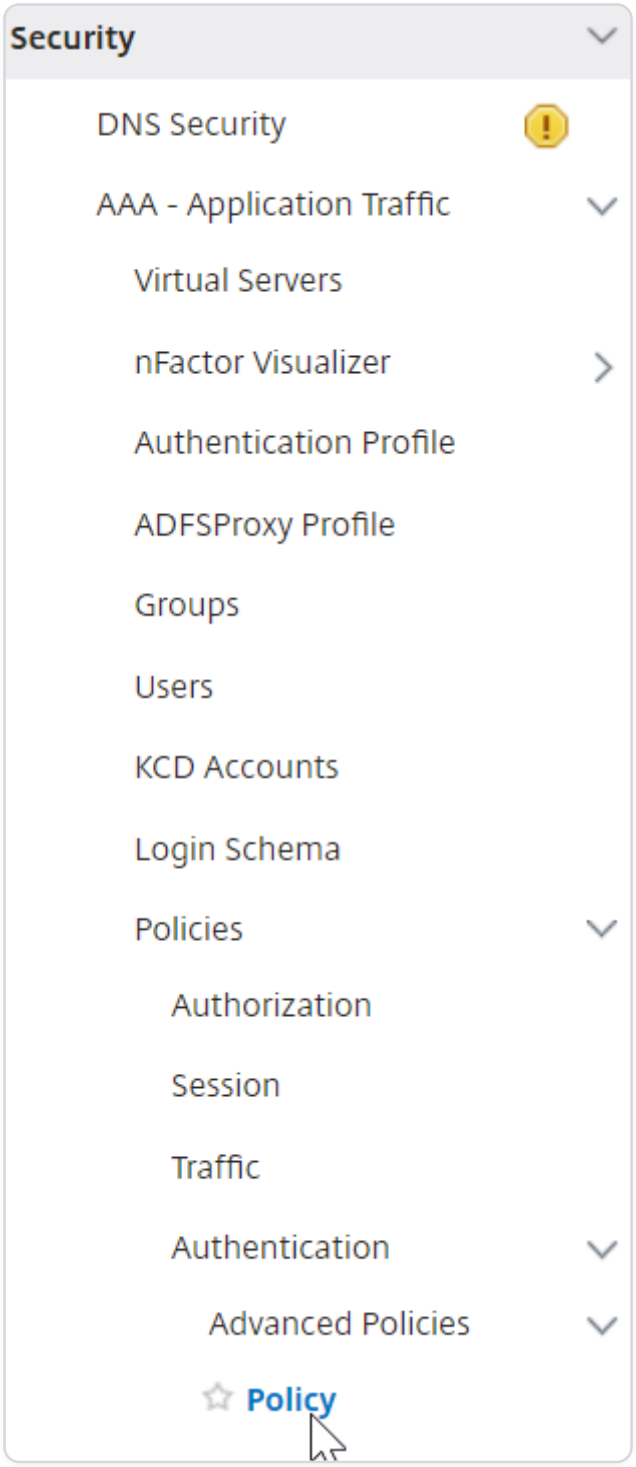
You need authentication actions/servers (for example LDAP, RADIUS, CERT, SAML, and so forth) When creating an advanced authentication policy, there's a plus (Add) icon that lets you create authentication actions/servers.

Or you can create authentication actions (servers) before creating the advanced authentication policy. The authentication servers are located under **Authentication > Dashboard**. On the right, click Add and select a Server Type. The instructions for creating these Authentication Servers are not detailed here. See the Authentication – NetScaler 12 / NetScaler 12.1 procedures.

To create an Advanced Authentication Policy:

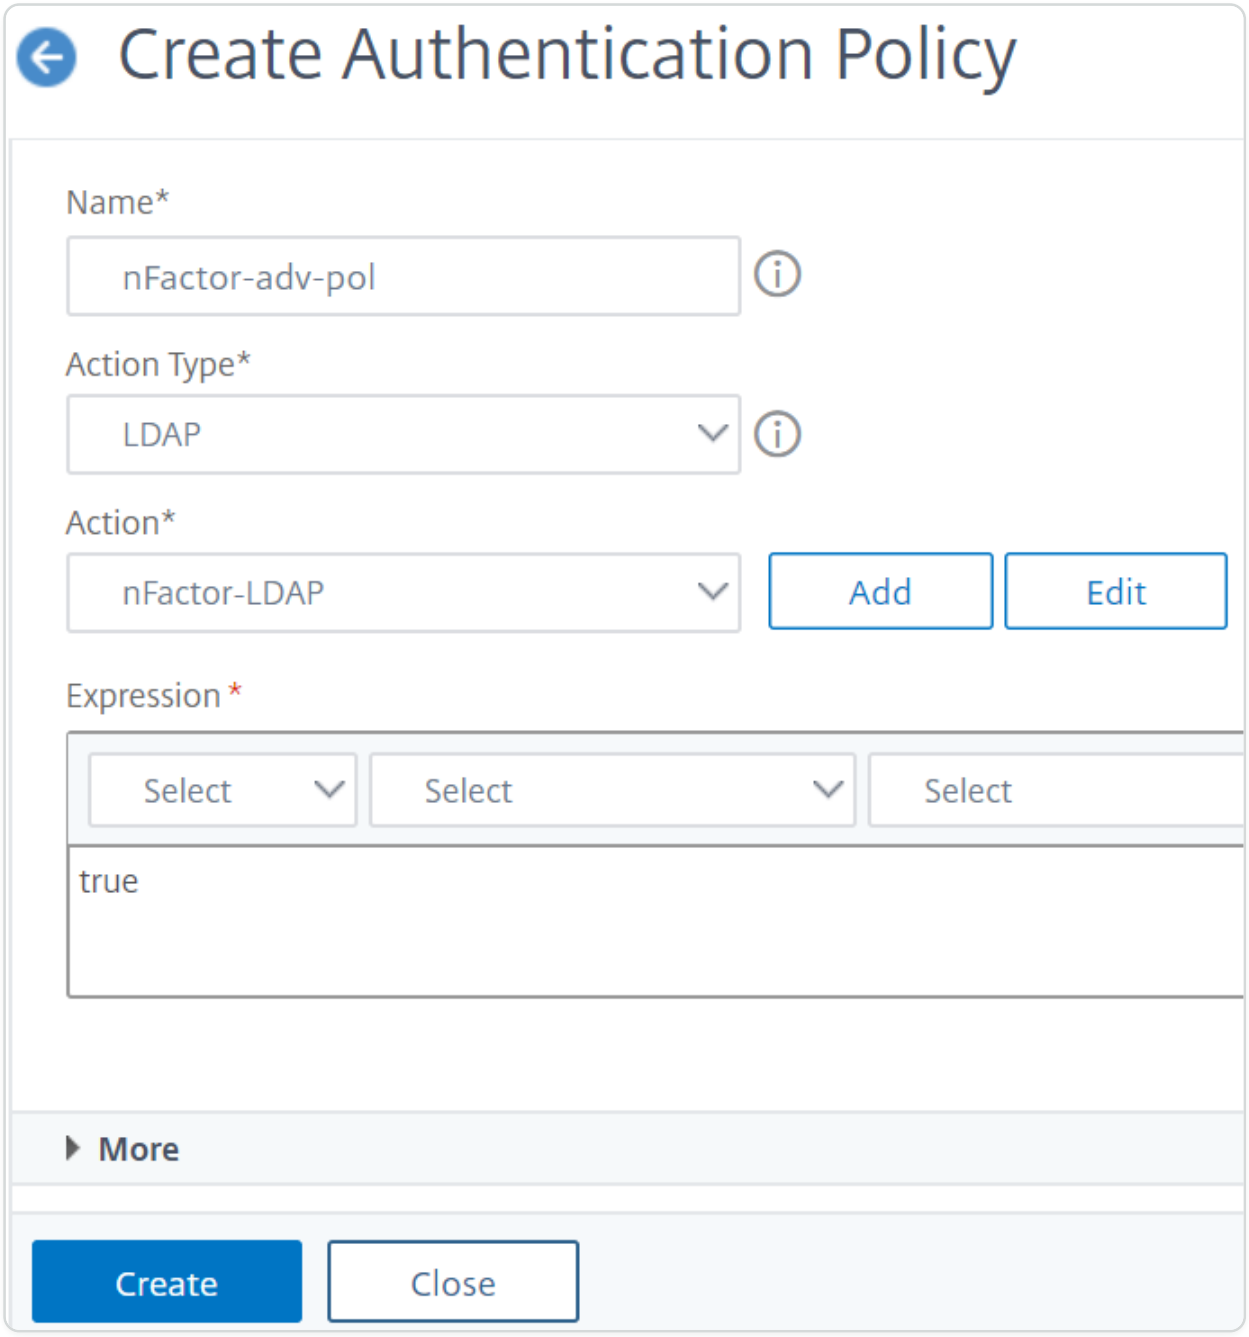
1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**

© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. In the details pane do one of the following:
   - To create a policy, click **Add**.
   - To modify an existing policy, select the policy, and then click **Edit**.
3. In the **Create Authentication Policy** or **Configure Authentication Policy** dialog box, type or select values for the parameters.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- **Name** - The policy name. Cannot be changed for a previously configured policy.
- **Action Type** - The policy type: Cert, Negotiate, LDAP, RADIUS, SAML, SAMLIDP, TACACS, or WEBAUTH.
- **Action** - The authentication action (profile) to associate with the policy. You can choose an existing authentication action, or click the plus and create an action of the proper type.
- **Log Action** - The audit action to associate with the policy. You can choose an existing audit action, or click the plus and create an action. You don't have any Actions configured, or to create an action, click **Add** and complete the steps.
- **Expression** - The rule that selects connections to which you want to apply the action that you specified. The rule can be simple ("true" selects all traffic) or complex. You enter

© 1997–2026 Citrix Systems, Inc. All rights reserved.

expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking Add to open Add Expression dialog box and using the drop-down lists in it to construct your expression.)

- **Comment** - You can type a comment that describes the type of traffic that this authentication policy applies to. Optional.

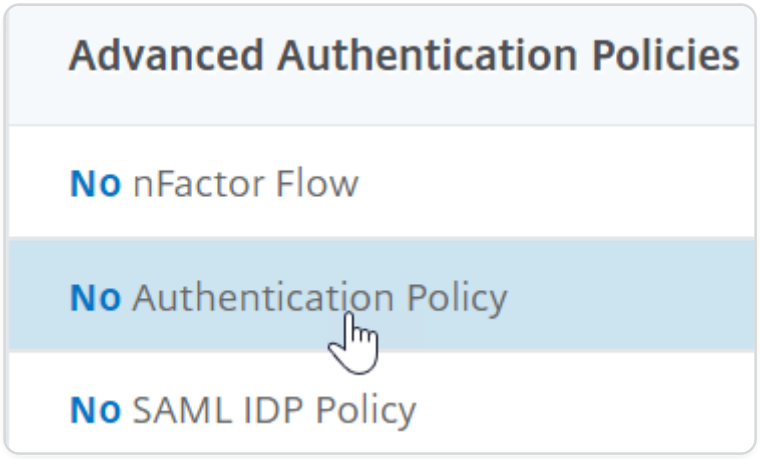
4. Click **Create** and then click **Close**. If you created a policy, that policy appears in the Authentication Policies and Servers page.

Create additional advanced authentication policies as required based on your nFactor design.

Bind first factor advanced authentication policy to authentication, authorization, and auditing

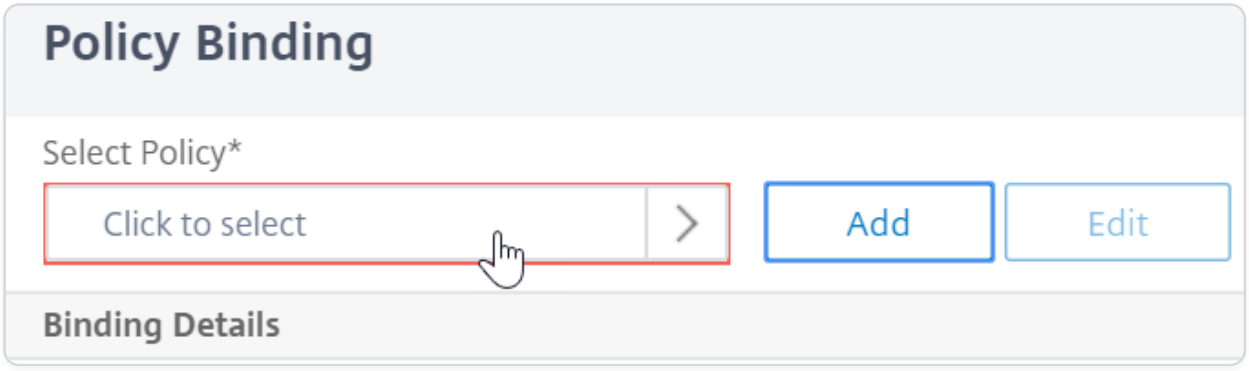
You can directly bind advanced authentication policies for the first Factor the authentication, authorization, and auditing virtual server. For the next factors, you must bind the advanced authentication policies to the authentication policy labels.

1. Navigate to **Security > AAA - Application Traffic > Virtual Servers**. Edit an existing virtual server.
2. On the left, in the Advanced Authentication Policies section, click **No Authentication Policy**.

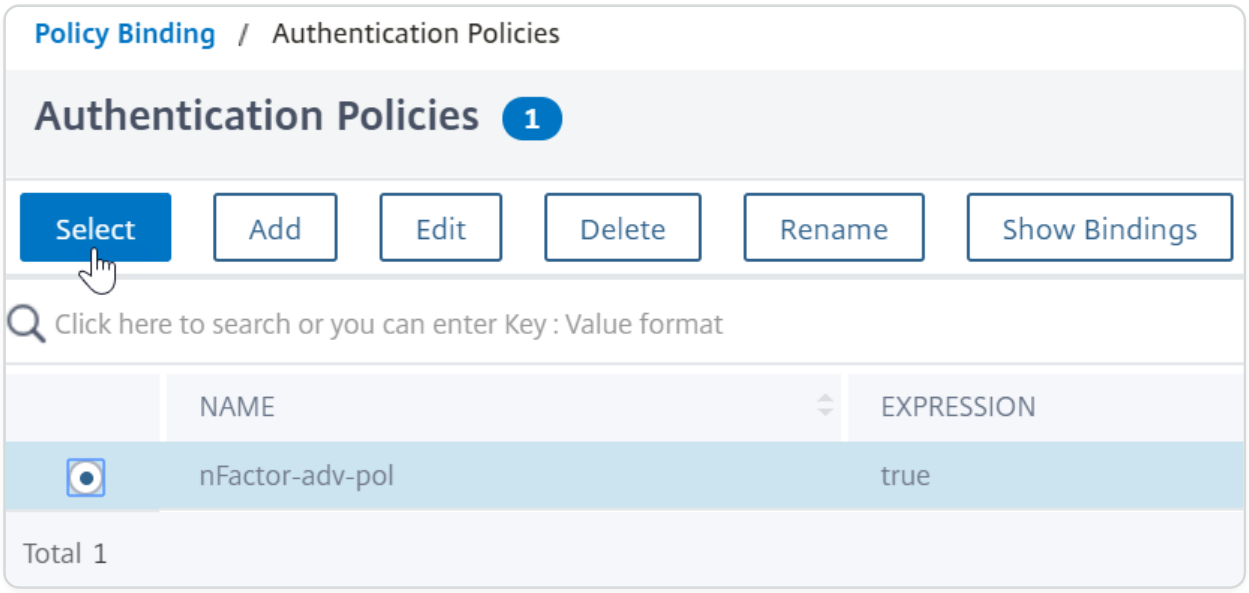


3. In **Select Policy**, click the text, **Click to select**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



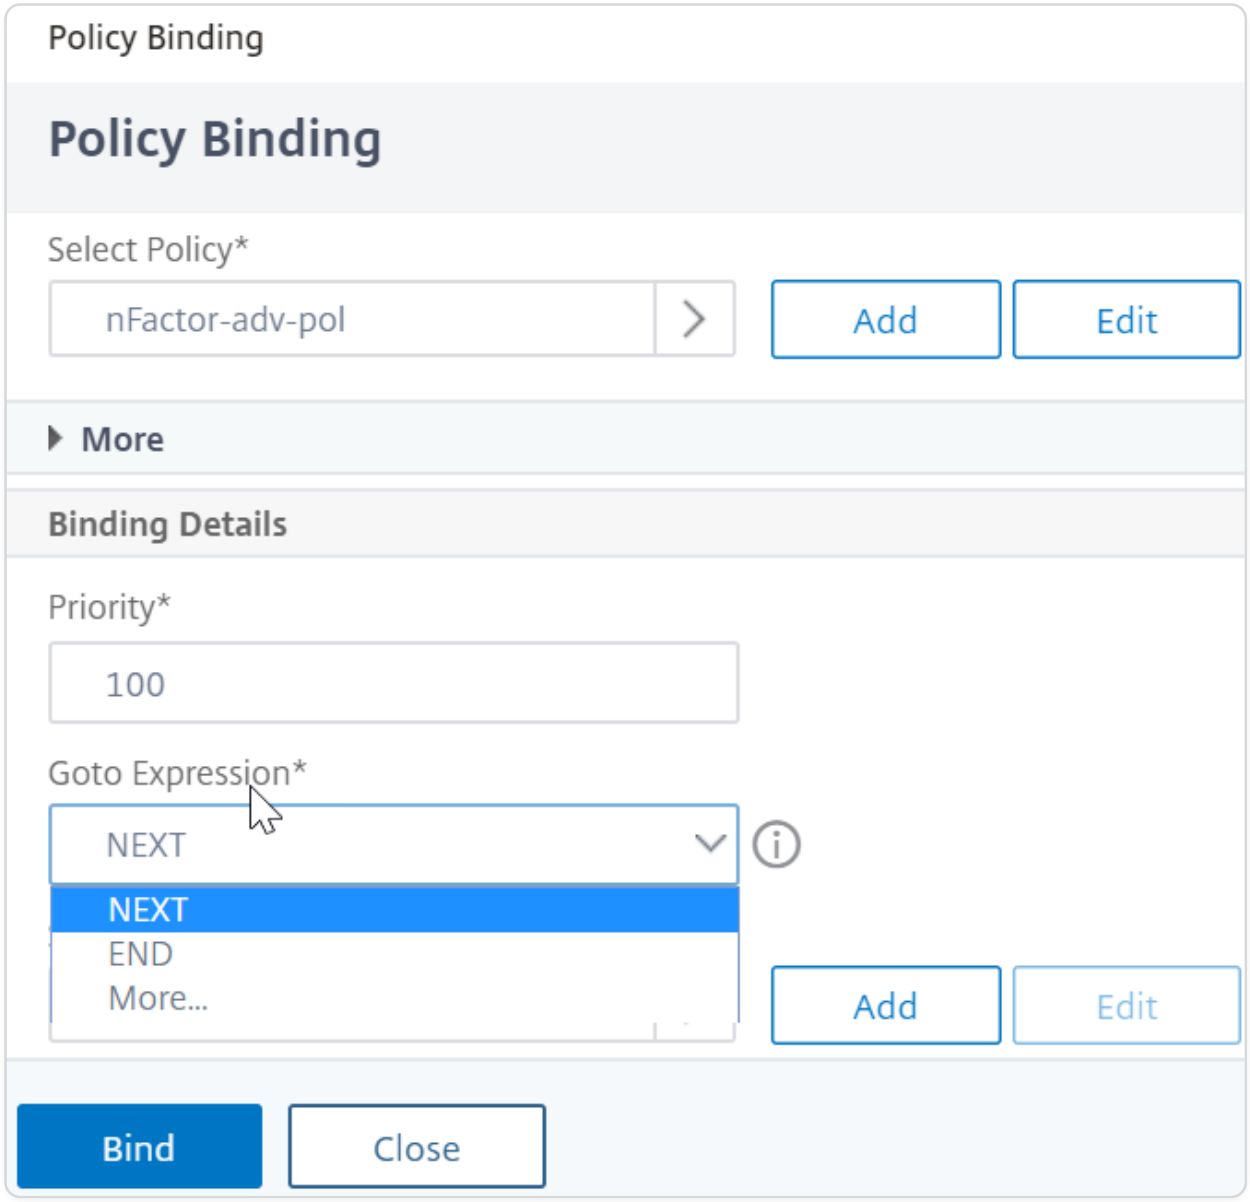
4. Click the radio button next to the **Advanced Authentication Policy**, and click **Select**.



5. In the Binding Details section, the **Goto Expression** determines what happens next if this advanced authentication policy fails.

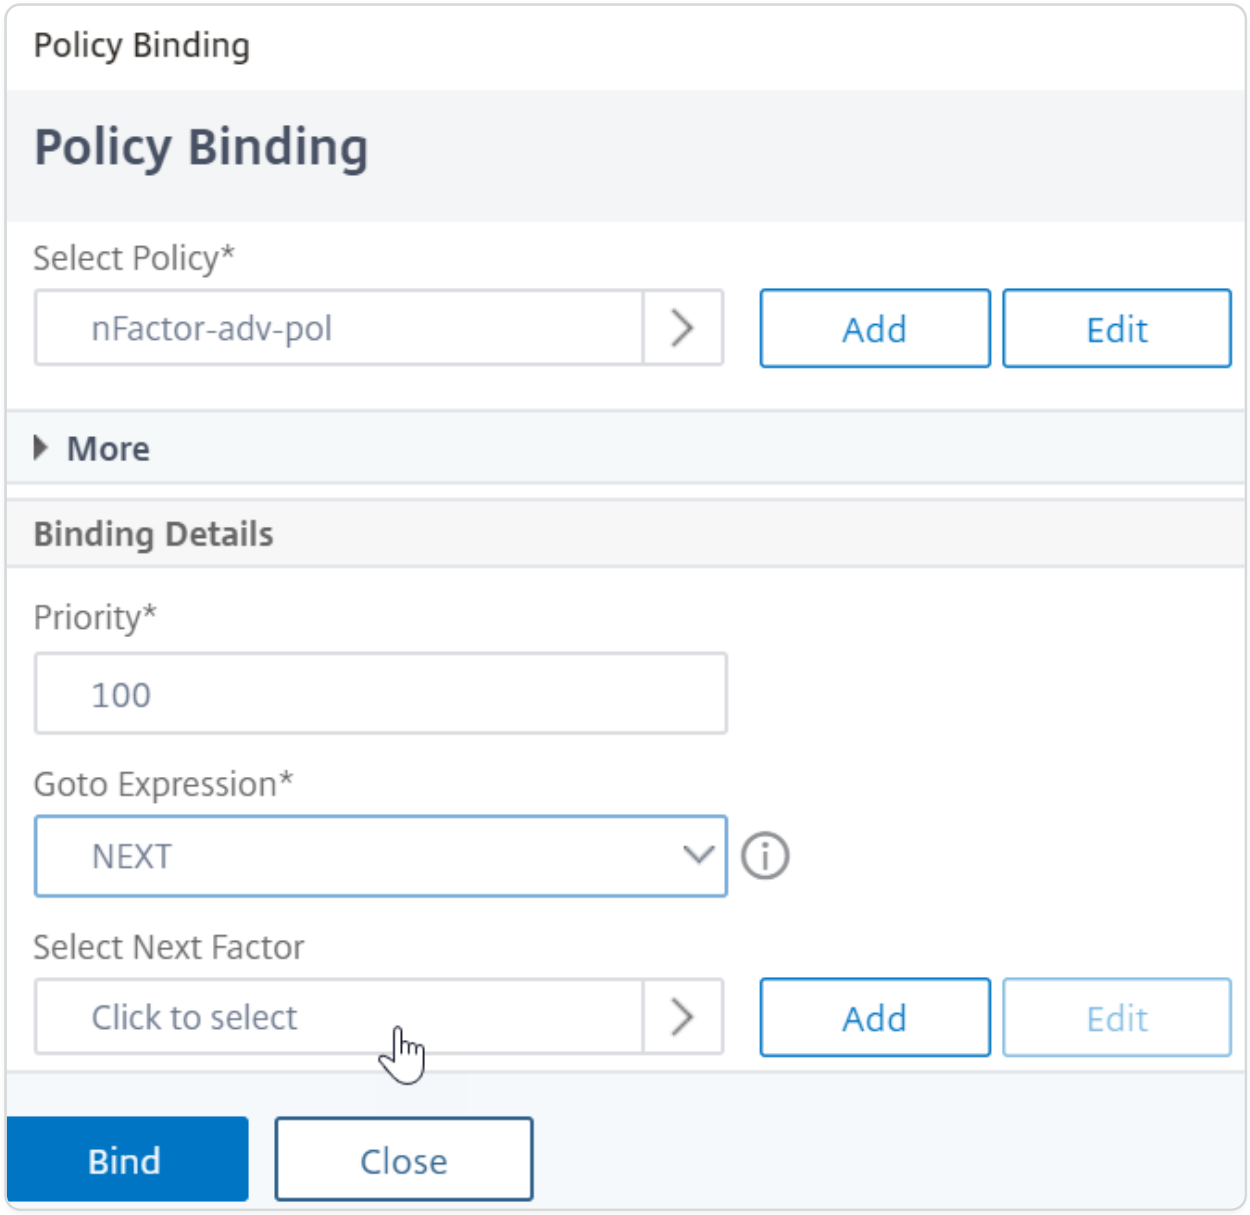
   - If **Goto Expression** is set to **NEXT**, then the next advanced authentication policy bound to this authentication, authorization, and auditing Virtual Server is evaluated.
   - If **Goto Expression** is set to **END**, or if there are no more advanced authentication policies bound to this authentication, authorization, and auditing virtual server, then authentication is completed and marked as failed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



6. In **Select Next Factor**, you can select can point to an authentication policy label. The next factor is evaluated only if the advanced authentication policy succeeds. Finally, click **Bind**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Use extracted LDAP groups to select the next authentication Factor

You can use extracted LDAP groups to select the next authentication factor without actually authentication with LDAP.

1. When creating or editing an LDAP server or LDAP action, clear the **Authentication** check box.
2. In **Other Settings**, select appropriate values in **Group Attribute** and **Sub Attribute Name**.

Authenticate the policy label

When you bind an advanced authentication policy to the authentication, authorization, and auditing Virtual Server and have selected a next factor, the next factor is evaluated only if the advanced authentication policy succeeds. The next factor that is evaluated is an authentication policy label.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The authentication policy label specifies a collection of authentication policies for a particular factor. Each policy label corresponds to a single factor. It also specifies the login form that must be presented to the user. The authentication policy label must be bound as the next factor of an authentication policy or of another authentication policy label.

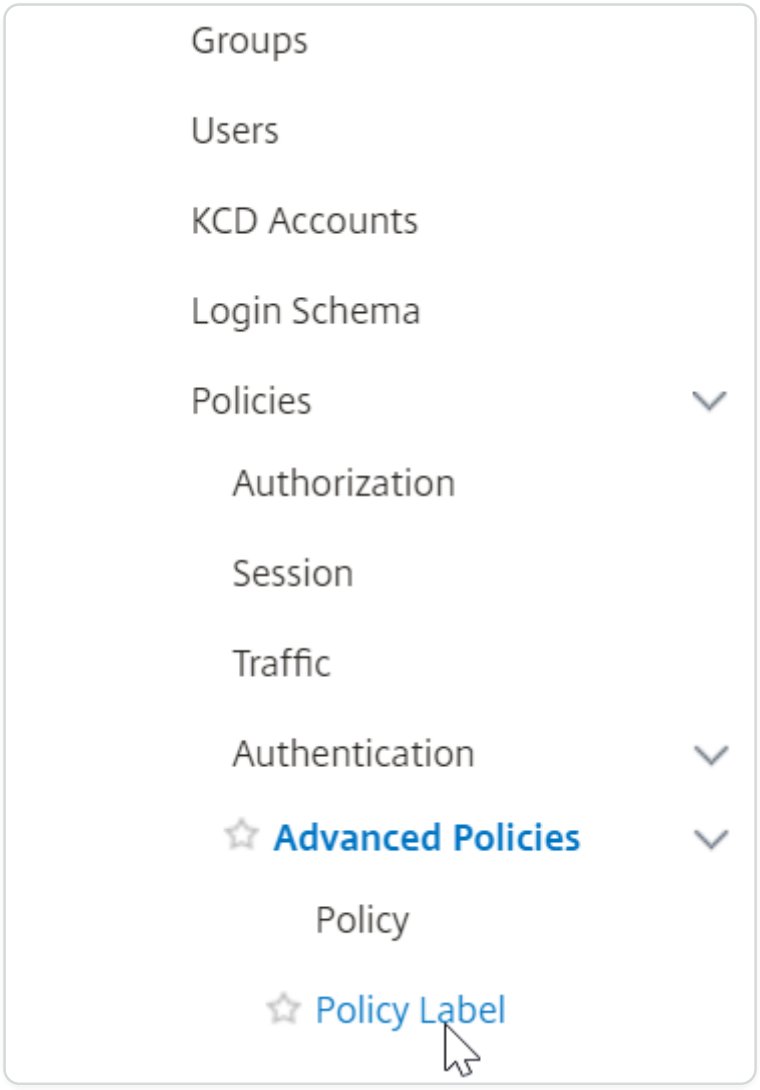
Note: Every factor does not need a login schema. Login schema profile is required only if you are binding a login schema to an Authentication Policy Label.

Create an authentication policy label

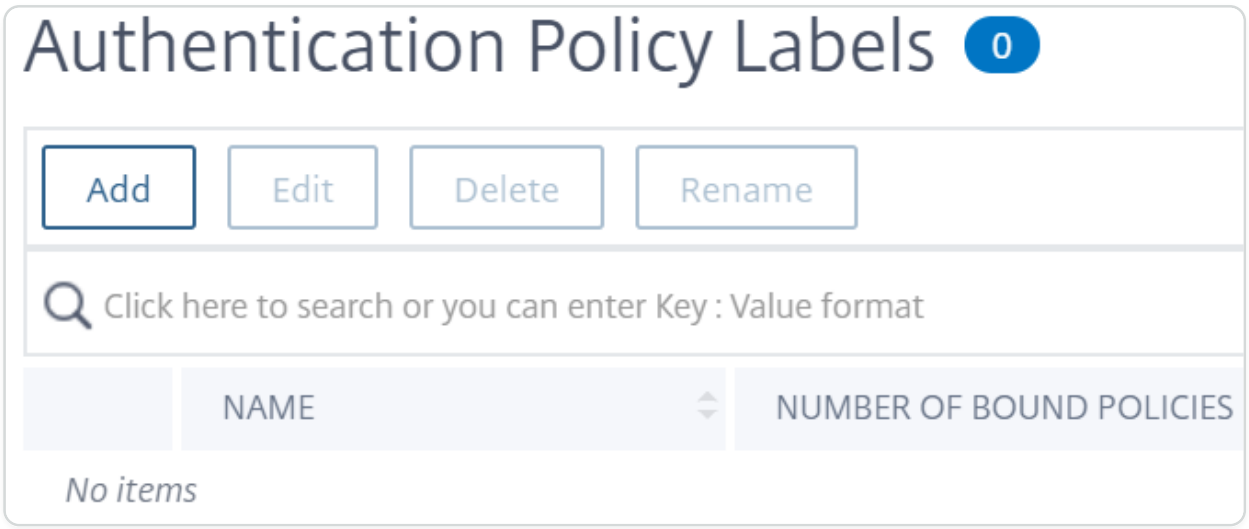
A policy label specifies the authentication policies for a particular factor. Each policy label corresponds to a single factor. The policy label specifies the login form that must be presented to the user. The policy label must be bound as the next factor of an authentication policy or of another authentication policy label. Typically, a policy label includes authentication policies for a specific authentication mechanism. However, you can also have a policy label that has authentication policies for different authentication mechanisms.

1. Navigate to **Security > AAA – Application Traffic > Policies > Authentication > Advanced Policies > Policy Label**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



2. Click the **Add** button.



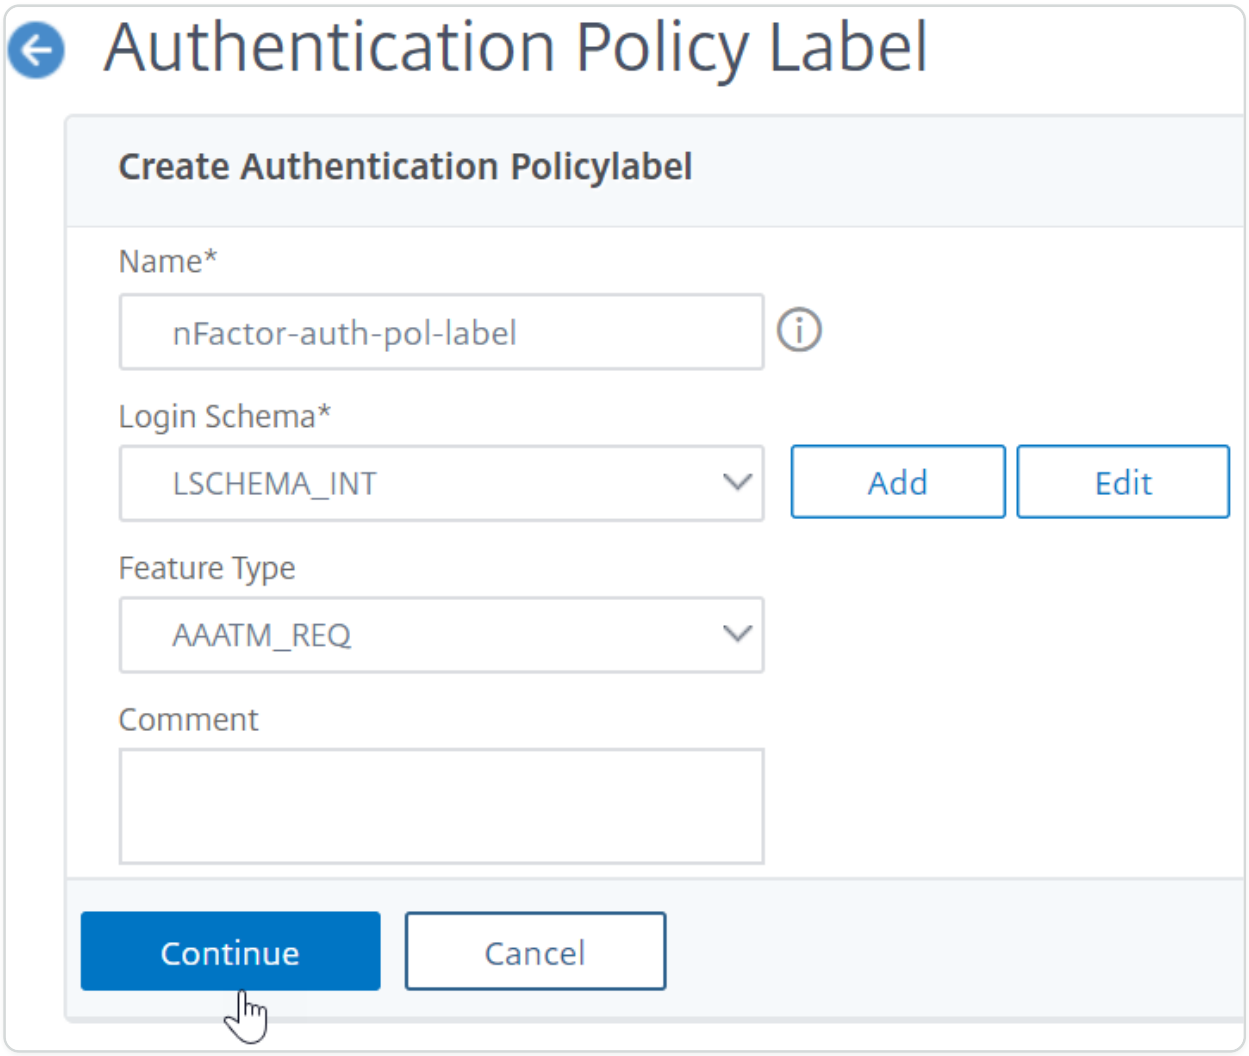
3. Complete the following fields to create an authentication policy label:

   a) Enter the **Name** for the new authentication policy label.

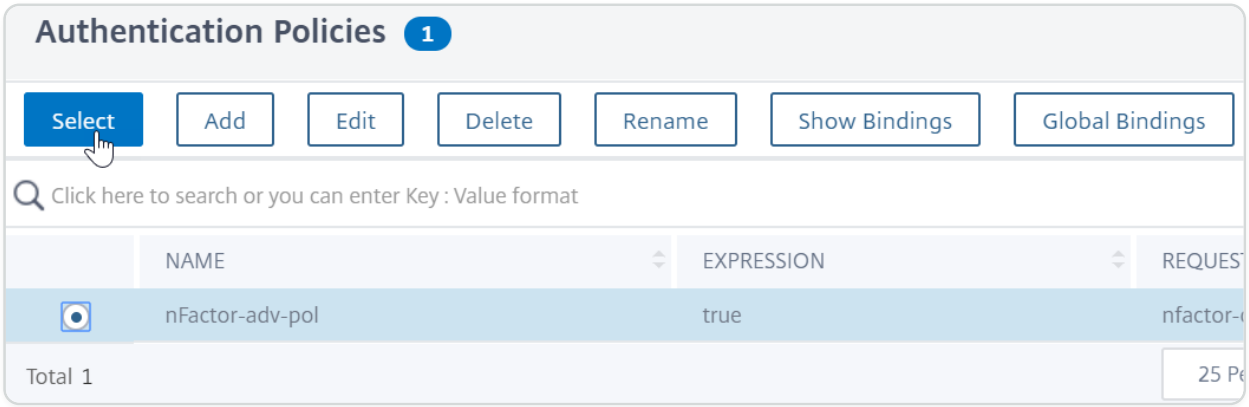
© 1997–2026 Citrix Systems, Inc. All rights reserved.

b) Select the **Login Schema** associated with authentication policy label. IF you do not want to display anything to the user, you can select a login schema profile that is set to no schema (LSCHEMA_INT).

c) Click **Continue**.



4. In the **Policy Binding** section, click where it says **Click to select**.
5. Select the authentication policy that evaluates this factor.

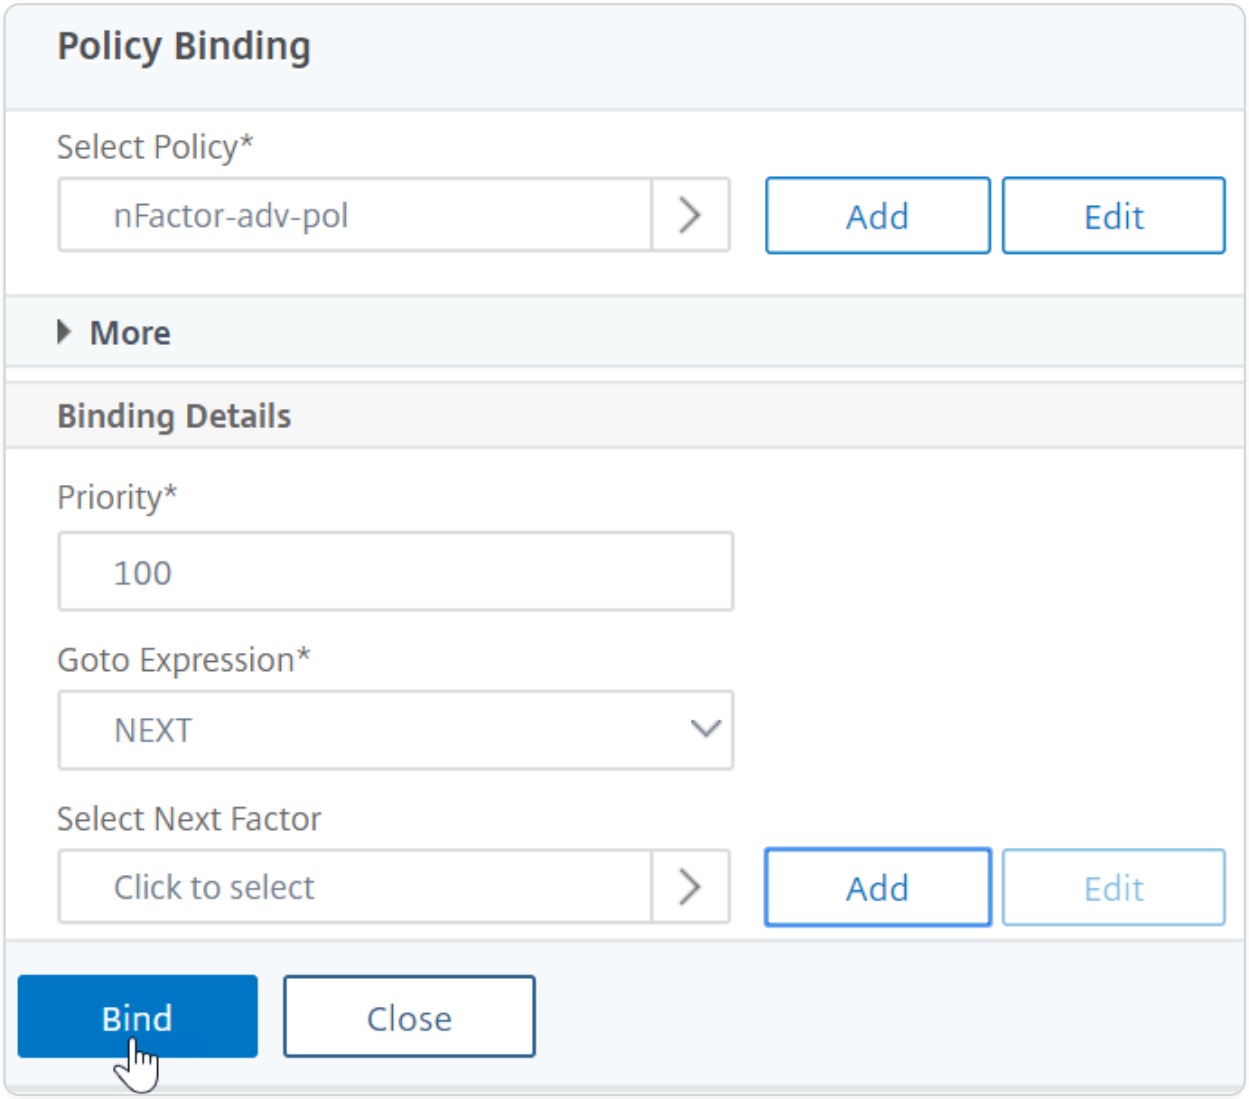


6. Complete the following fields:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

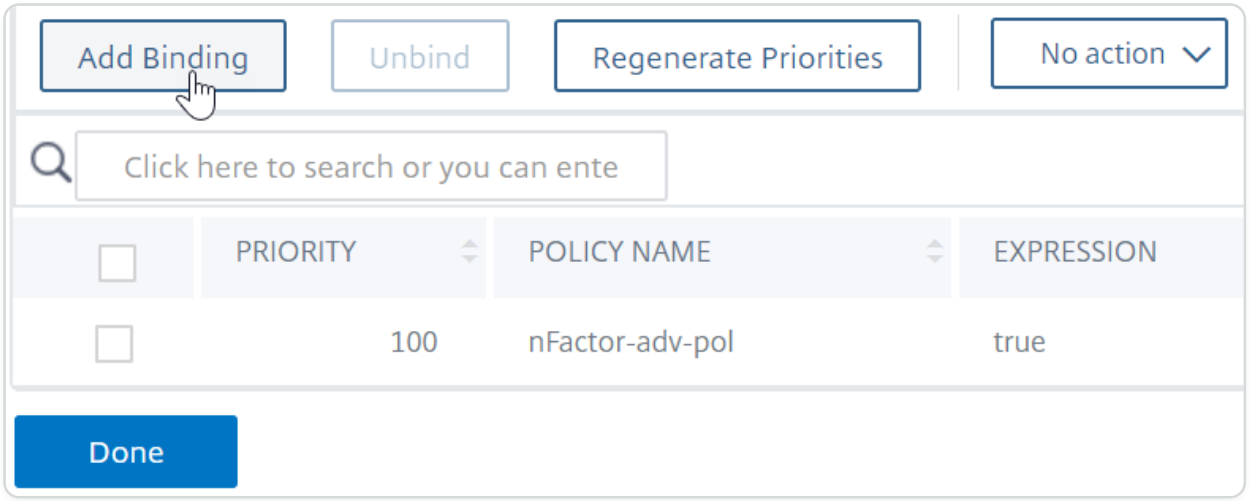
a) Enter the **Priority** of the policy binding.

b) In **Goto Expression** select **NEXT** if you want to bind more advanced authentication policies to this factor or select **END**.



7. In **Select Next Factor**, if you want to add another factor, click to select and bind the next authentication policy label (next factor). If you do not select the next factor, and if this advanced authentication policy succeeds, then authentication is successful and complete.
8. Click **Bind**.
9. You can click **Add Binding** to add more advanced authentication policies to this policy label (factor). Click **Done** upon completion.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



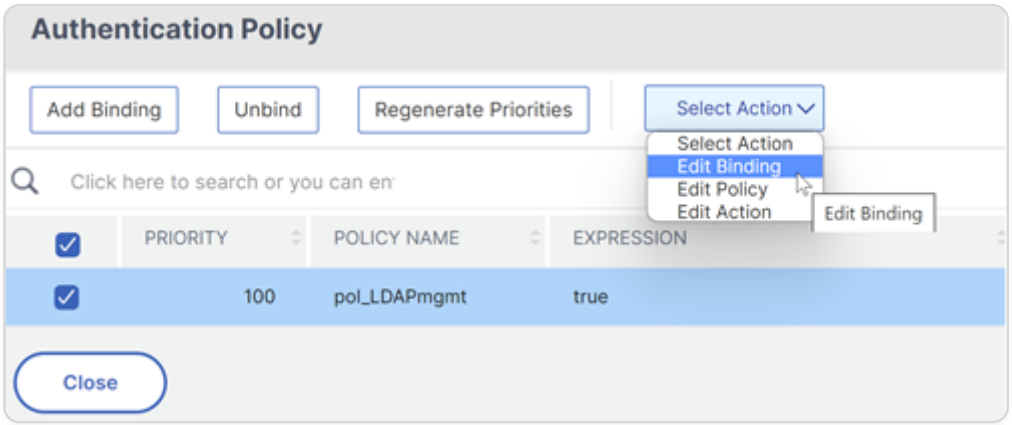
Bind authentication policy label

After you create the policy label, you bind it to an existing advanced authentication policy binding to chain the factors together.

You can select the next factor when editing an existing authentication, authorization, and auditing virtual server that has an advanced authentication policy bound or when editing a different policy label to include the next factor.

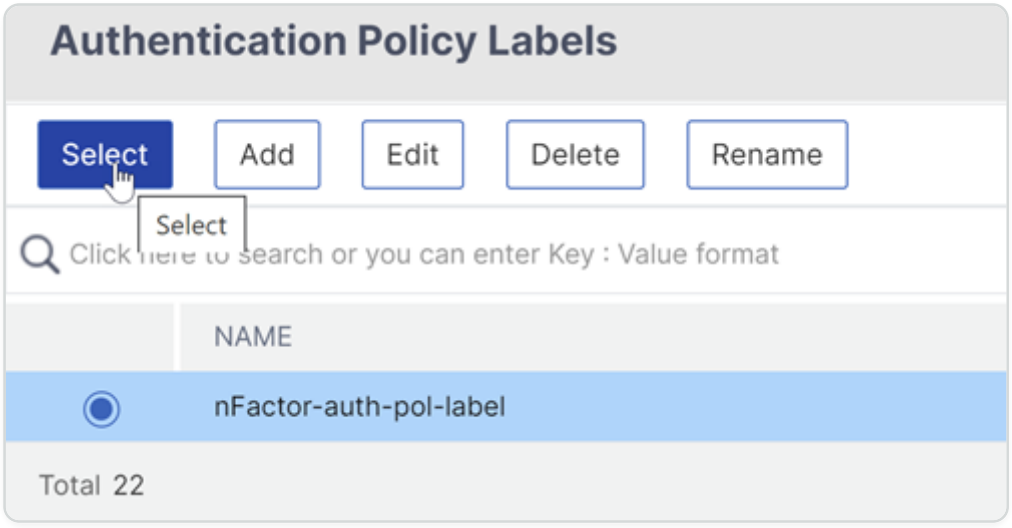
To edit an existing authentication, authorization, and auditing virtual server that has an advanced authentication policy already bound to it

1. Navigate to **Security > AAA – Application Traffic > Virtual Servers.** Select the virtual server and click **Edit**.
2. On the left, in the **Advanced Authentication Policies** section, click an existing authentication policy binding.
3. In **Select Action**, click **Edit Binding**.

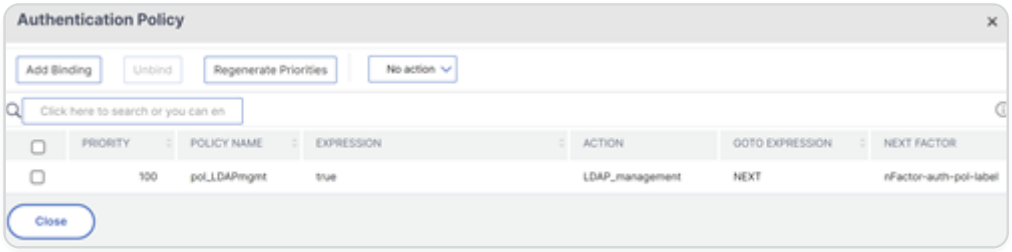


4. Click **Select Next Factor** and select an existing authentication policy label (next factor).

© 1997–2026 Citrix Systems, Inc. All rights reserved.

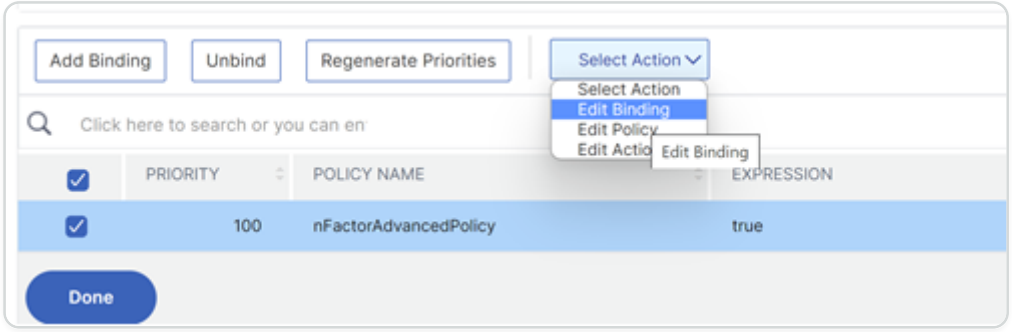


5. Click **Bind** in the **Policy Binding** page. You can see the **NEXT FACTOR** column with the next factor details on the extreme right.



To add a policy label next factor to a different policy label

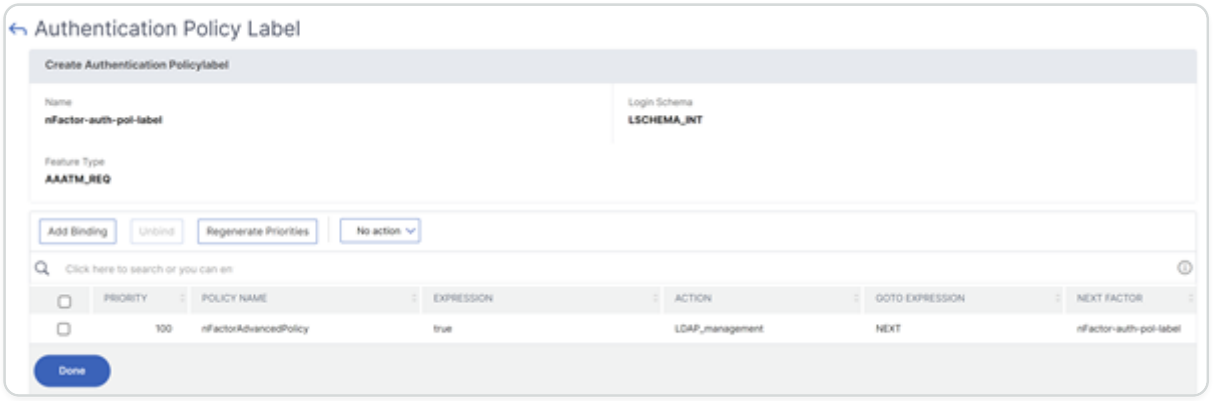
1. Navigate to **Security > AAA – Application Traffic > Policies > Authentication > Advanced Policies > PolicyLabel**.
2. On the **Authentication Policy Labels** page, select an authentication policy label and click **Edit.**
3. On the **Authentication Policies** page, select an authentication policy label and in **Select Action**, click **Edit Binding**.



4. In **Binding Details > Select Next Factor**, click to select the next factor.
5. Choose the policy label for the next factor and click the **Select** button.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

6. Click **Bind** in the **Policy Binding** page. On the **Authentication Policy Label** page, you can see the **NEXT FACTOR** column with the next factor details on the extreme right.

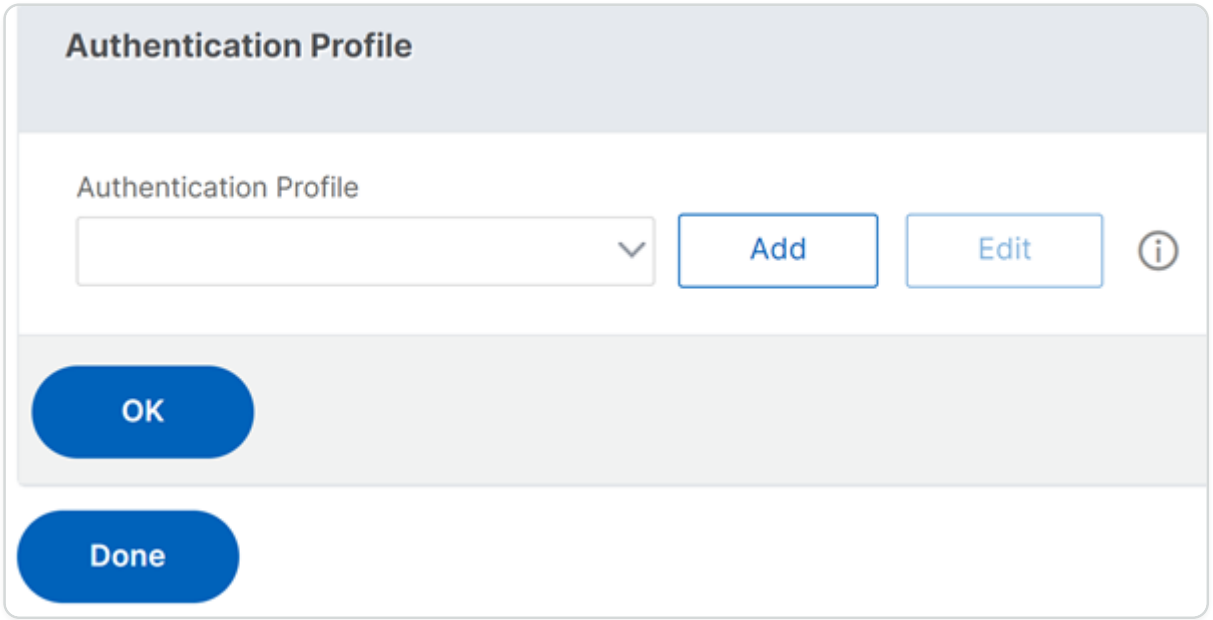


nFactor for NetScaler Gateway

To enable nFactor on the NetScaler Gateway, an authentication profile must be linked to an authentication, authorization, and auditing virtual server.

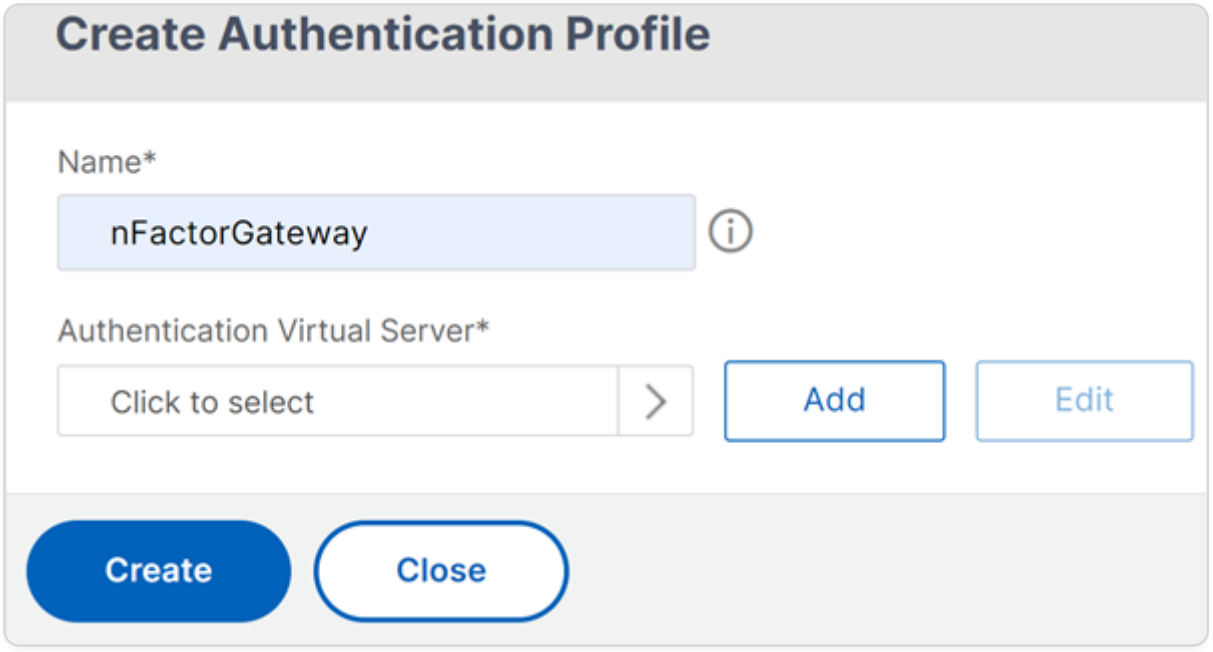
Create authentication profile to link an authentication, authorization, and auditing virtual server with NetScaler Gateway virtual server

1. Navigate to **NetScaler Gateway > Virtual Servers** and select and existing gateway virtual server to edit.
2. In **Advanced Settings**, click **Authentication Profile**.
3. Click **Add** under **Authentication Profile**

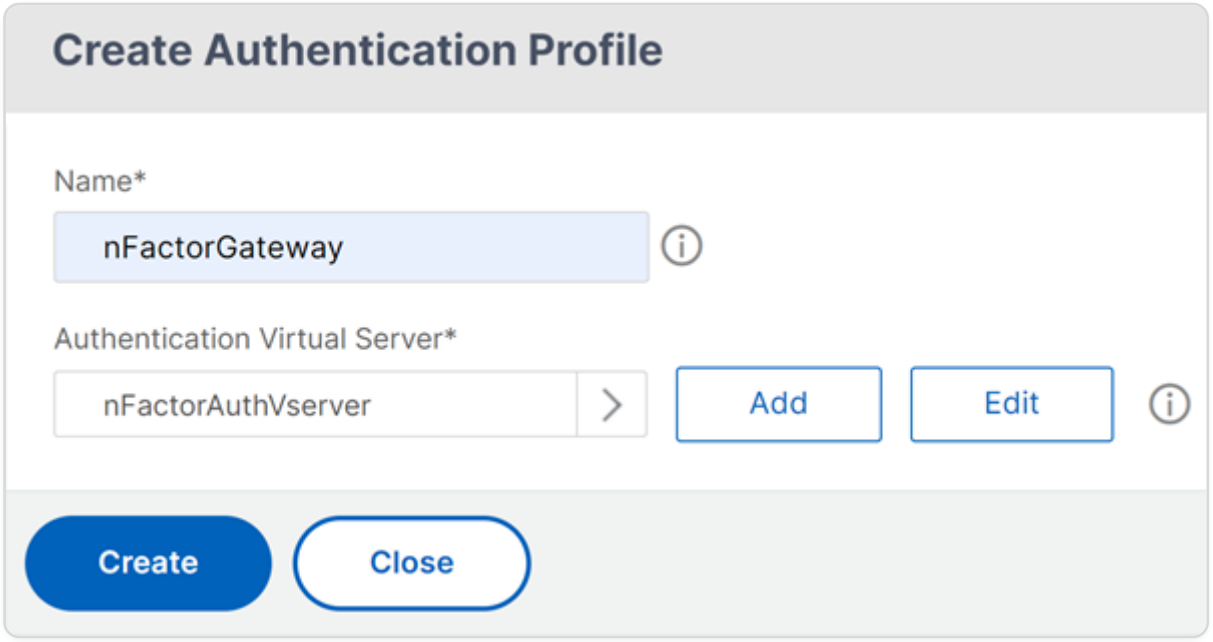


4. Enter the name for the authentication profile and click where it says **Click to select**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. In **Authentication Virtual Server**, select an existing server that has login schema, advanced authentication policy, and authentication policy labels configured. You can also create an authentication virtual server. The authentication, authorization, and auditing virtual server does not need an IP address. Click **Select**.
6. Click **Create**.



7. Click **OK** to close the Authentication Profile section.

Note: If you have configured one of the factors as client certificates, then must configure the SSL parameters and CA certificate.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

After you have completed linking the authentication profile to an authentication, authorization, and auditing virtual server, and when you browse to your NetScaler Gateway, you can view the nFactor authentication screens.

Configure SSL parameters and CA certificate

If one of the authentication factors is a certificate, then you must perform some SSL configuration on the NetScaler Gateway virtual server.

1. Navigate to **Traffic Management > SSL > Certificates > CA Certificates**, and install the root certificate for the issuer of the client certificates. Certificate Authority certificates do not need key files.

   If default SSL Profiles are enabled, then you have already created an SSL Profile that has Client Authentication enabled.
2. Navigate to **NetScaler Gateway > Virtual Servers**, and edit an existing NetScaler Gateway virtual server that is enabled for nFactor.
   - If default SSL Profiles are enabled, click the edit icon.
   - In the SSL Profile list, select the SSL Profile that has Client Authentication enabled and set to OPTIONAL.
   - If default SSL Profiles are not enabled, click the edit icon.
   - Check the Client Authentication check box.
   - Ensure that Client Certificate is set to Optional
3. Click OK.
4. In Certificates section, click **No CA Certificate.**
5. In Select CA Certificate, click to select and select the root certificate for the issuer of the client certificates.
6. Click Bind.

Note: You might have to also bind any Intermediate CA Certificates that issued the client certificates.

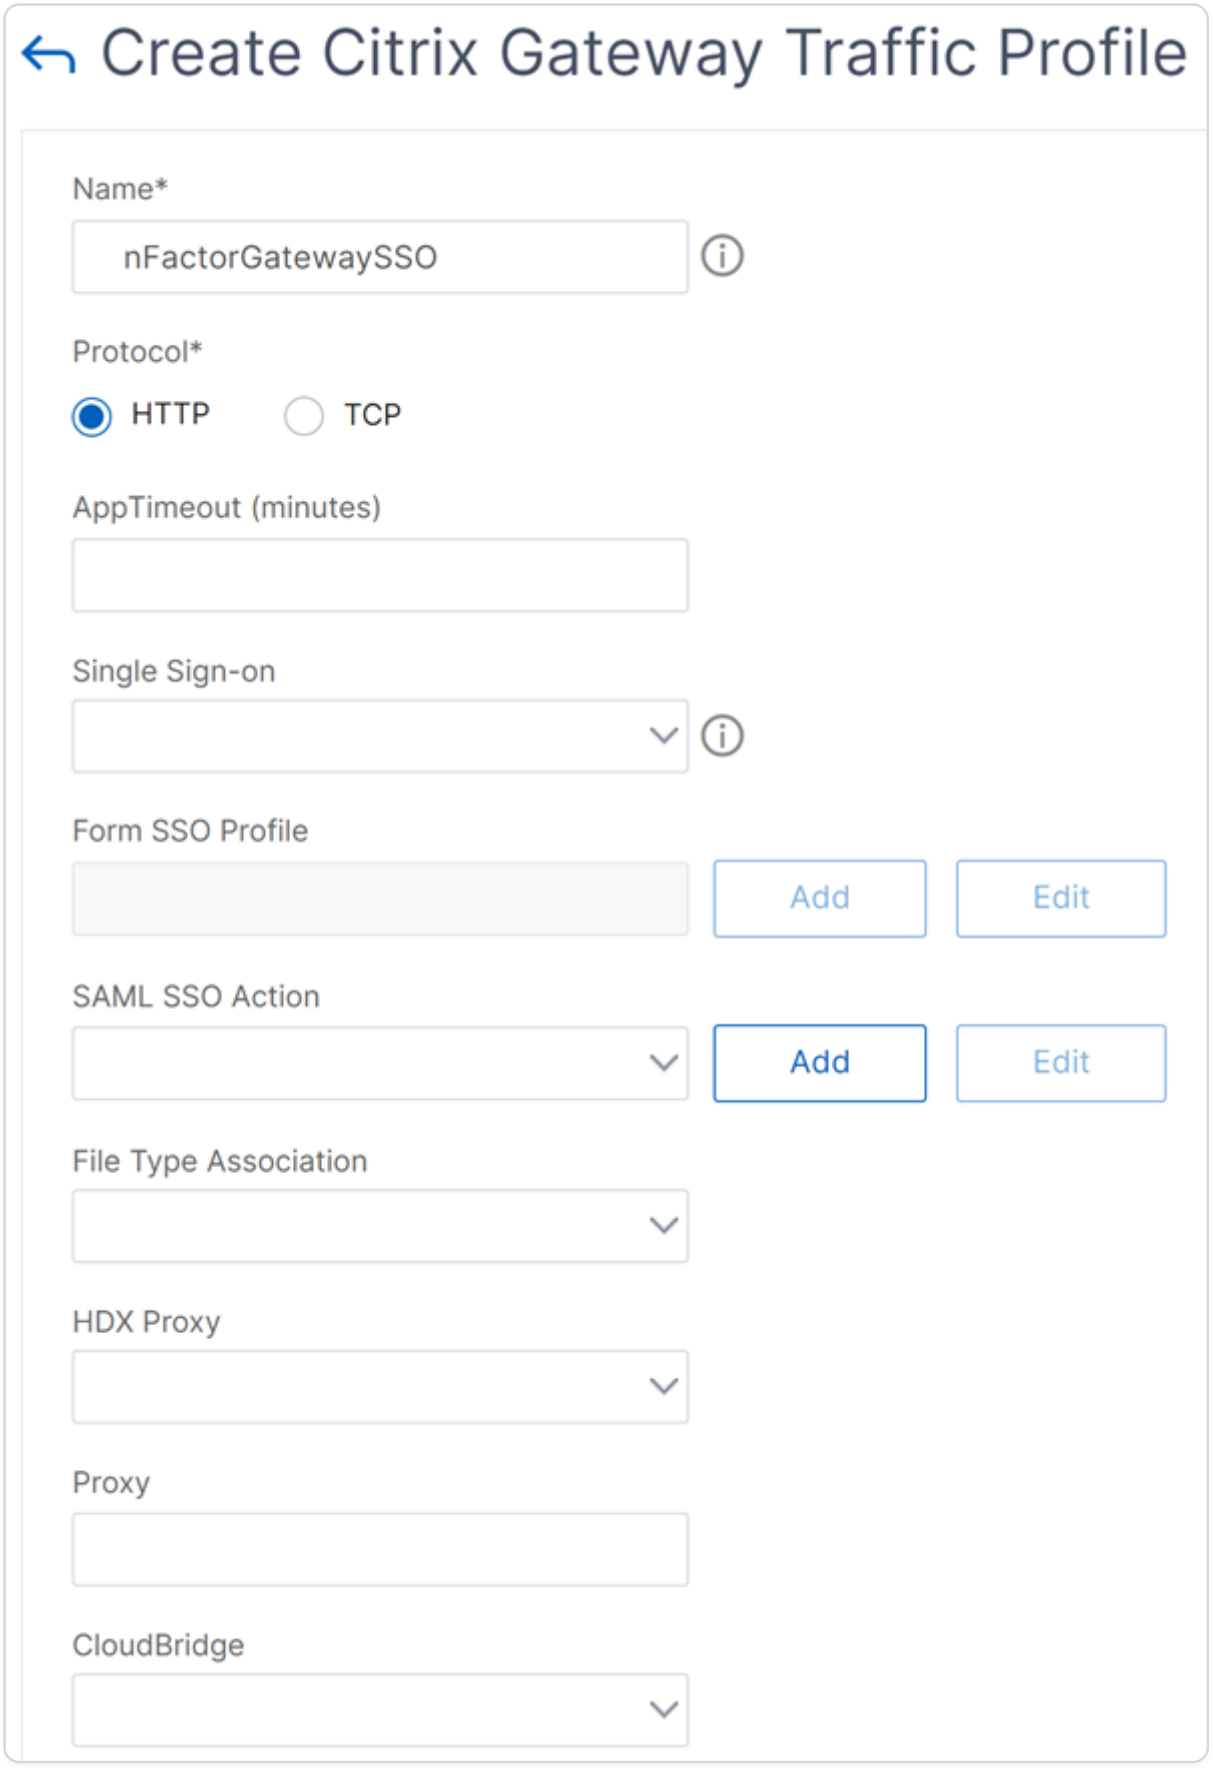
Configure NetScaler Gateway traffic policy for nFactor single sign-on to StoreFront

For single sign-on to StoreFront, nFactor defaults to using the last entered password. If LDAP is not the last entered password, then you must create a traffic policy/profile to override the default nFactor behavior.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Navigate to **NetScaler Gateway > Policies > Traffic**.
2. In the **Traffic Profiles** tab, click **Add**.
3. Enter a name for the traffic profile. Select the **HTTP** protocol. In **Single Sign-on**, select **ON**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

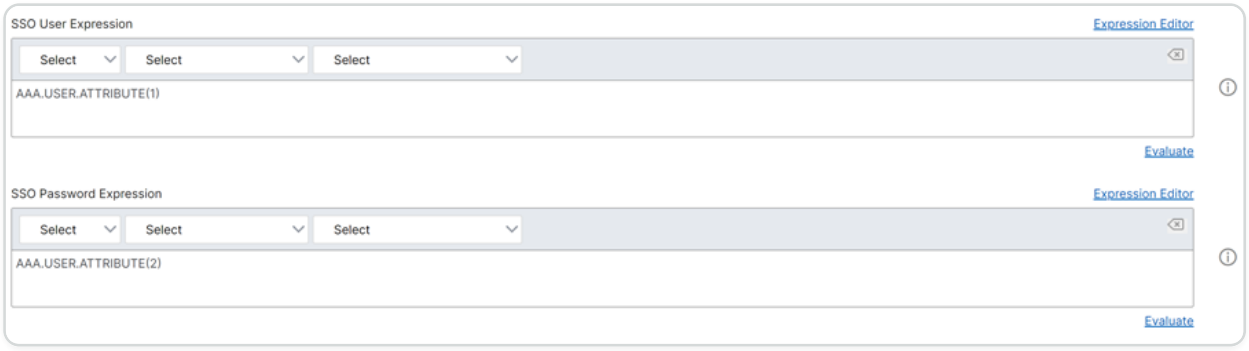


4. In the **SSO Expression**, enter a AAA.USER.ATTRIBUTE(#) expression that matches the indexes specified in the login schema and click **Create**.

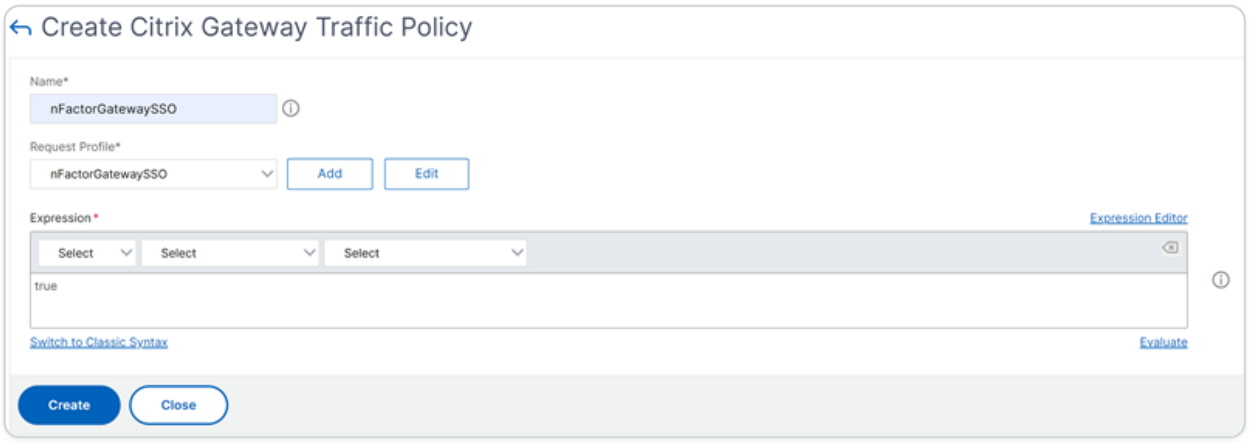
© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

AAA.USER expression is now implemented to replace the deprecated HTTP.REQ.USER expressions.



5. Click **Traffic Policies** tab, and click **Add**.
6. Enter a name for the policy. Select the traffic profile created in the previous step. In **Expression**, enter an advanced expression, and click **Create**.



7. Navigate to **NetScaler Gateway > NetScaler Gateway Virtual Server**.
   - Select and existing virtual server and click **Edit**.
   - In the **Policies** section, click the **+** sign.
   - In **Choose Policy**, select **Traffic**.
   - In **Choose Type**, select **Request**.
   - Select the traffic policy that you have created and then click **Bind**.

Sample snippet on nFactor configuration by using the CLI

To understand the step-wise configurations for nFactor authentication, let us consider a two-factor authentication deployment where the first factor is LDAP authentication and the second factor is RADIUS authentication.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

This sample deployment requires the user to log in to both factors using a single login form. Therefore, we define a single login form that accepts two passwords. The first password is used for LDAP authentication and the other for RADIUS authentication. Here are the configurations that are performed:

1. Configure the load balancing virtual server for authentication

   add lb vserver lbvs89 HTTP 1.136.19.55 80 -AuthenticationHost auth56.aaatm.com -Authentication ON

2. Configure the authentication virtual server.

   add authentication vserver auth56 SSL 10.106.30.223 443 -AuthenticationDomain aaatm.com

3. Configure the login schema for the login form and bind it to a login schema policy.

   add authentication loginSchema login1 -authenticationSchema login-2passwd.xml -userCredentialIndex 1 -passwordCredentialIndex 2

   Note:

   Use the user name and one of the passwords entered in the login schema for single sign-on (SSO) to a back-end service, for example StoreFront. You can reference these index values in the traffic action by using the expression AAA.USER.ATTRIBUTE(#). The values can be between 1 and 16.

   Alternatively, you can use the credentials entered in the login schema as your Single Sign-On credentials by using the following command.

   ```
   add authentication loginSchema login1 -authenticationSchema
   login-2passwd.xml -SSOCredentials YES

    add authentication loginSchemaPolicy login1 -rule true -action login1
   ```

4. Configure a login schema for the pass-through and bind it to a policy label

   ```
   add authentication loginSchema login2 -authenticationSchema noschema
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication policylabel label1 -loginSchema login2
```

5. Configure the LDAP and RADIUS policies.

```
add authentication ldapAction ldapAct1 -serverIP 10.17.103.28 -ldapBase
"dc=aaatm, dc=com" -ldapBindDn administrator@aaatm.com
-ldapBindDnPassword
81qw1b99ui971mn1289op1abc12542389b1f6c111n0d98e1d78ae90c8545901
-encrypted -encryptmethod ENCMTHD\_3 -ldapLoginName samAccountName
-groupAttrName memberOf -subAttributeName CN

add authentication Policy ldap -rule true -action ldapAct1

add authentication radiusAction radius -serverIP 10.101.14.3 -radKey
n231d9a8cao8671or4a9ace940d8623babca0f092gfv4n5598ngc40b18876hj32
-encrypted -encryptmethod ENCMTHD\_3 -radNASip ENABLED -radNASid
NS28.50 -radAttributeType 11 -ipAttributeType 8

add authentication Policy radius -rule true -action radius
```

6. Bind the login schema policy to the authentication virtual server

```
bind authentication vserver auth56 -policy login1 -priority 1
-gotoPriorityExpression END
```

7. Bind the LDAP policy (first factor) to the authentication virtual server.

```
bind authentication vserver auth56 -policy ldap -priority 1 -nextFactor
label1 -gotoPriorityExpression next
```

8. Bind the RADIUS policy (second factor) to the authentication policy label.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind authentication policylabel label1 -policyName radius -priority 2
-gotoPriorityExpression end
```

NFactor configuration using the latest visualizer

IMPORTANT INFORMATION:

This topic contains instructions to configure the nFactor flow using the latest visualizer. The old visualizer described in the nFactor Visualizer for simplified configuration article is planned for deprecation in the upcoming releases.

Starting from release 14.1 build 29.x, NetScaler supports the latest nFactor visualizer. The latest visualizer is an enhanced version of the old visualizer. It provides a new look and feel, and is more intuitive than the old visualizer.

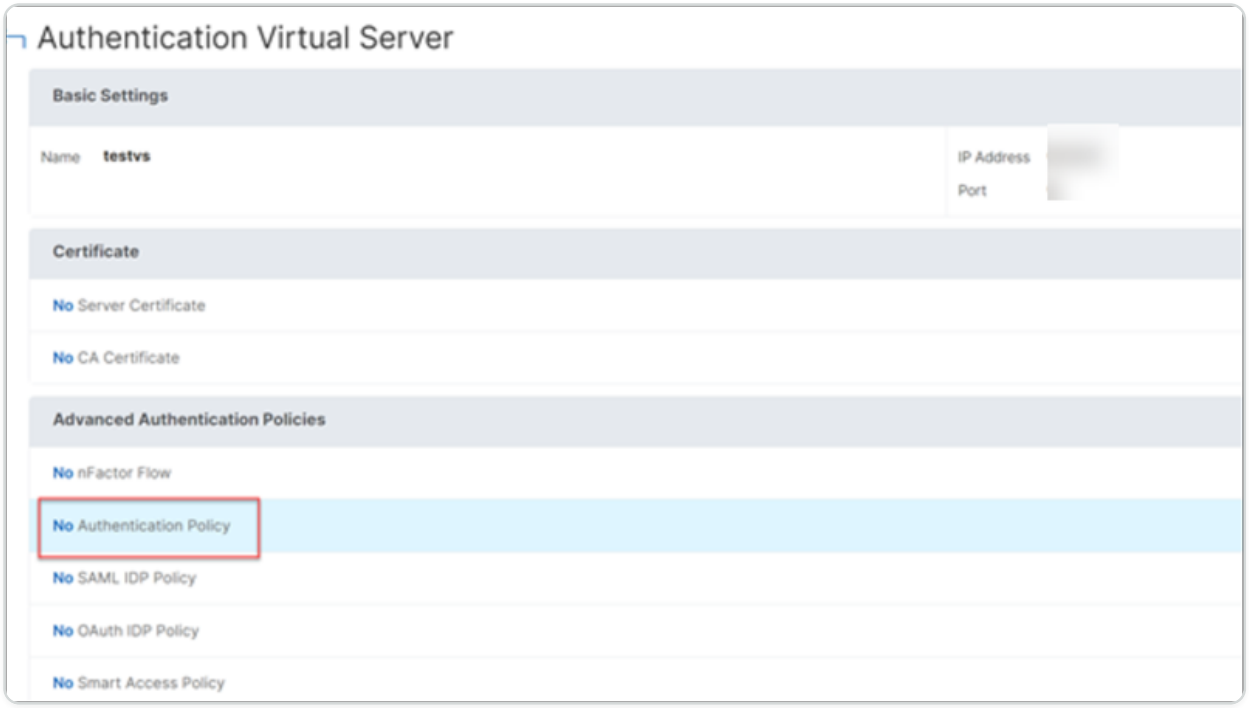
The latest visualizer supports the following features:

- You can build a prototype of your nFactor flow even before configuring the associated entities such as policies, login schema, and authentication server. The old visualizer allowed you to create the second factor only after the policies and login schema of the first factor are configured.
- The View nFactor option is introduced on the Authentication Policy page. This page displays a summary of the nFactor flows created. For the flows configured using the GUI or CLI, NetScaler automatically displays them on the latest visualizer.
- When creating the nFactor flow, you can name its entities at any point. This functionality is not supported in the old visualizer.

To configure the nFactor flow using the latest visualizer:

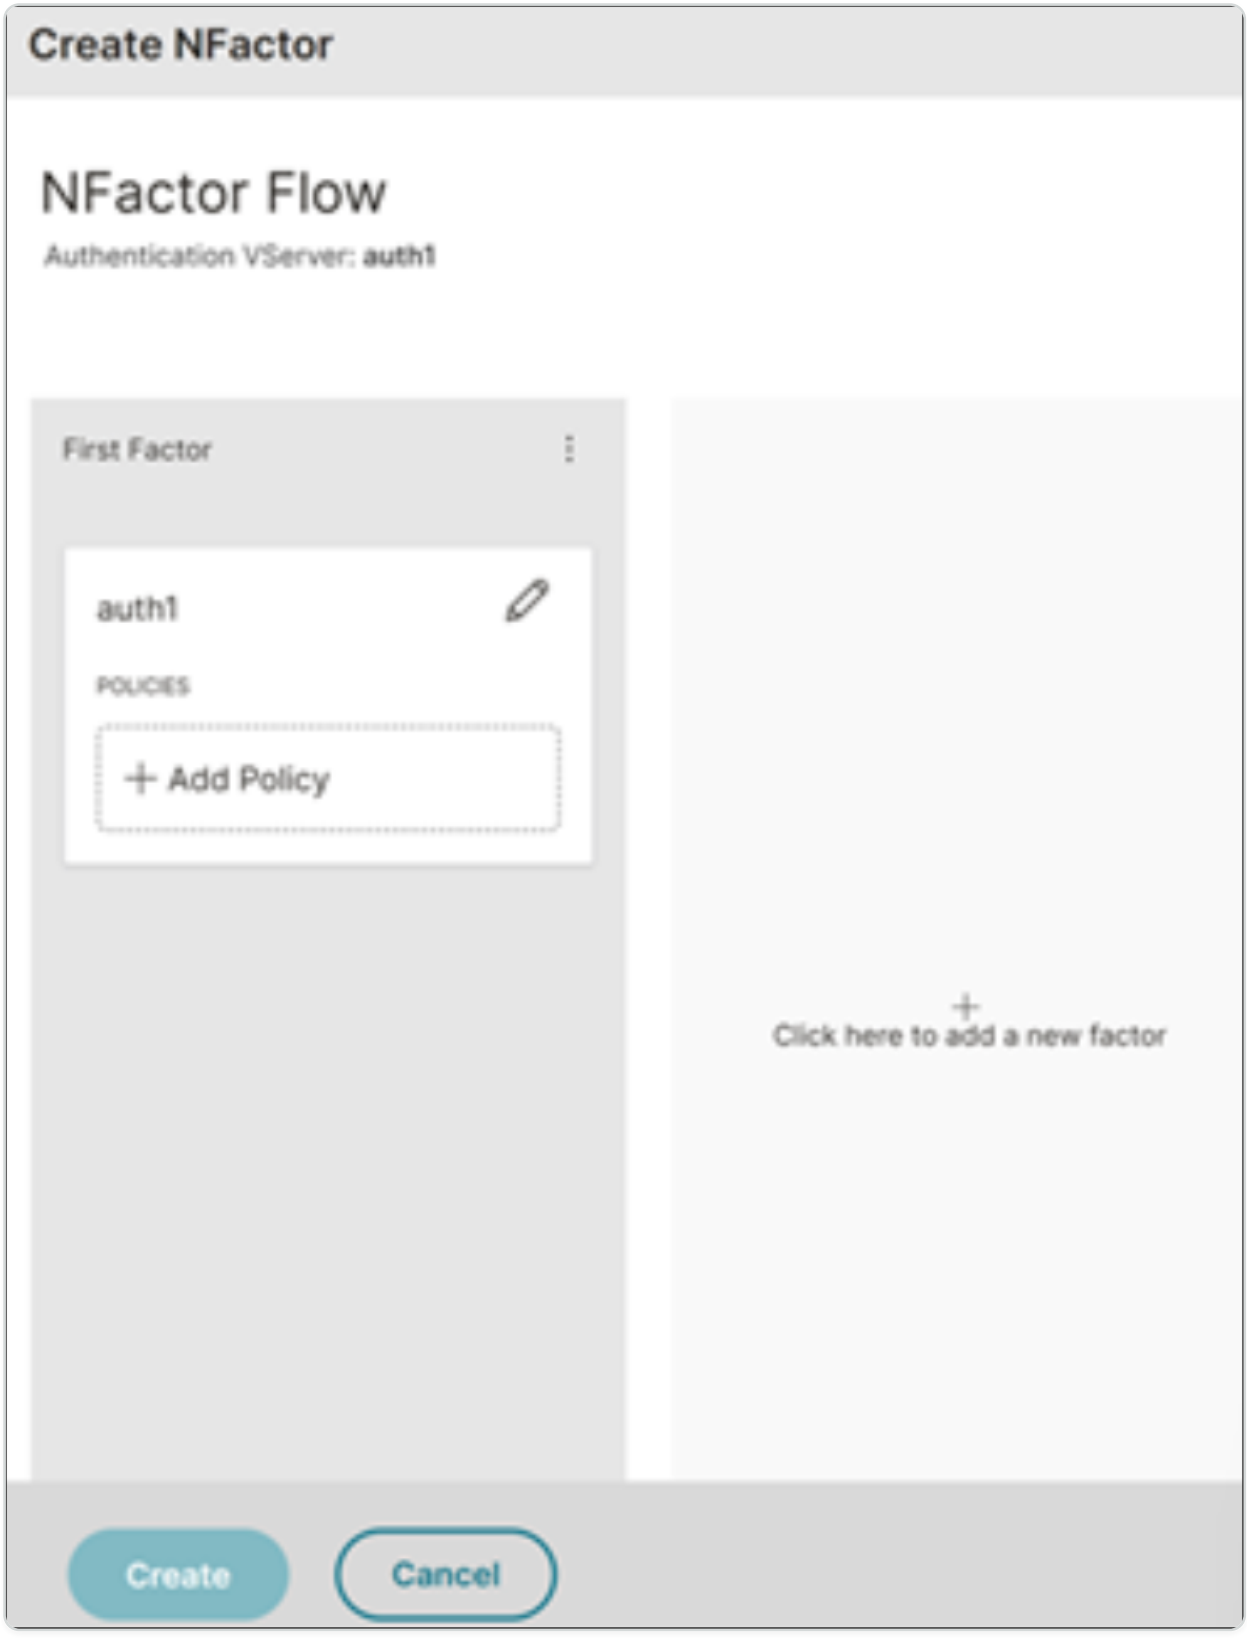
1. Navigate to **Security > AAA-Application traffic > Virtual Servers**.
2. Select an authentication virtual server and click **Edit**.
3. In the **Advanced Authentication Policies** section, select the authentication policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



4. On the **Create NFactor** page, configure the nFactor flow.

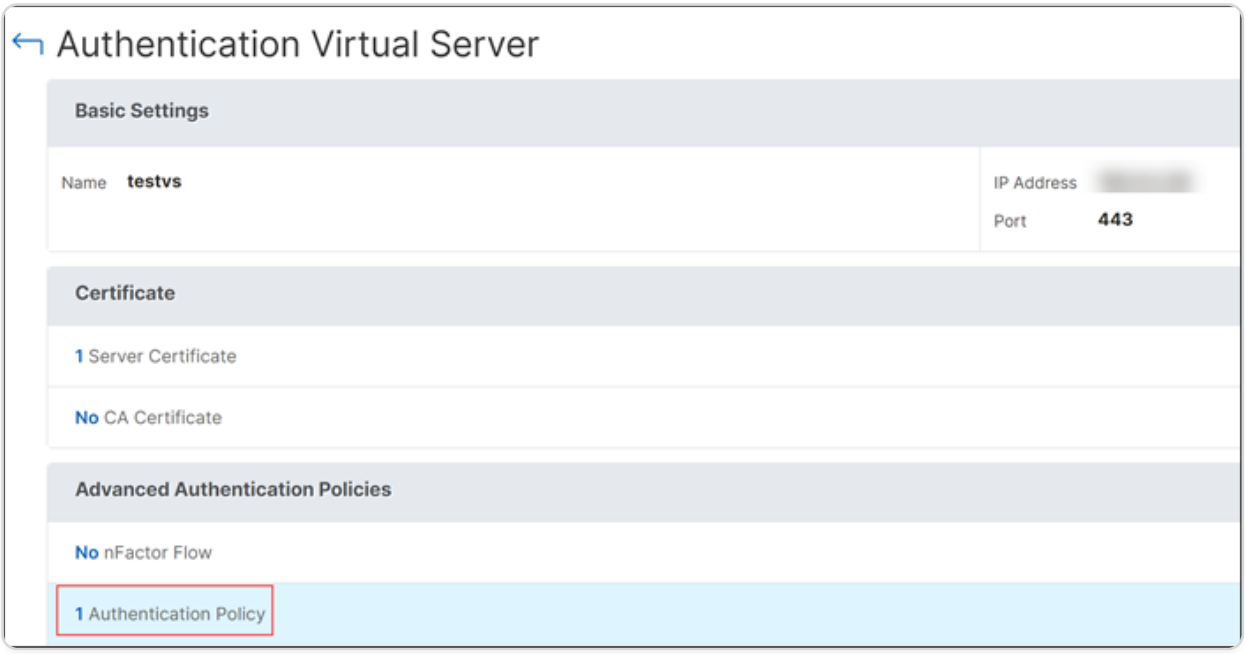
© 1997–2026 Citrix Systems, Inc. All rights reserved.



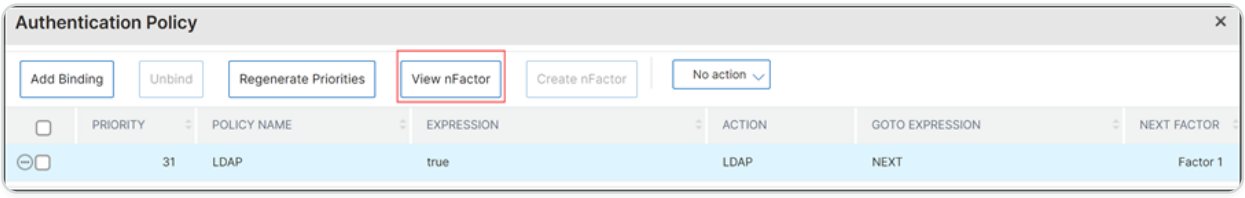
View the nFactor flow

1. Navigate to **Security > AAA - Application Traffic > Authentication Virtual Servers**.
2. On the **Authentication Virtual Server** page, select the authentication policy under **Advanced Authentication Policies**.

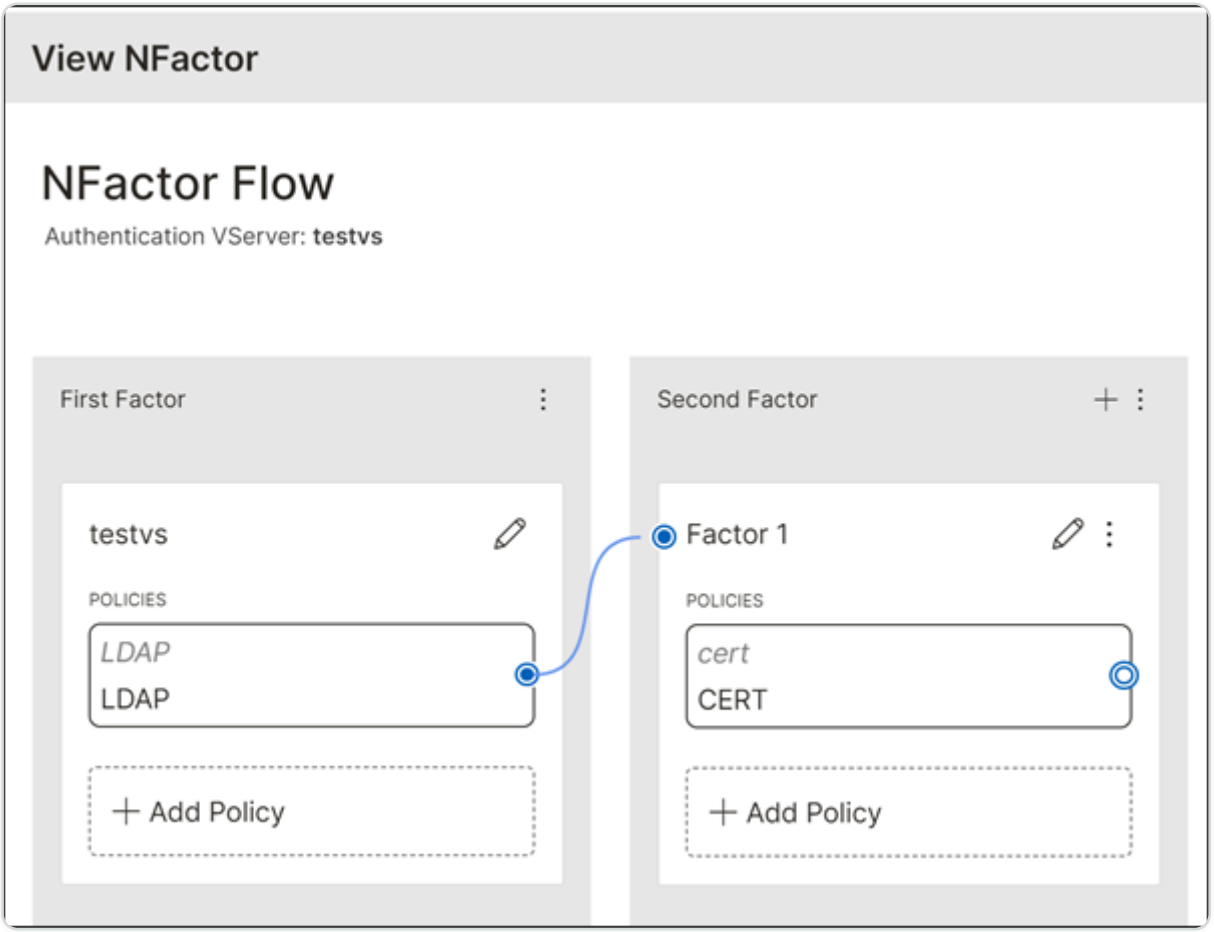
© 1997–2026 Citrix Systems, Inc. All rights reserved.



3. On the **Authentication Policy** page, select the policy and click **View nFactor**.



You can now view a summary of your nFactor flow.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTES:

- Currently, NetScaler does not support modifying an nFactor flow once created.
- When configuring a flow, if an entity (login schema, policy, or policy label) is created with a duplicate name, the GUI displays an error without specifying the name of the duplicate entity. Clicking **Create** results in the loss of the entire flow.

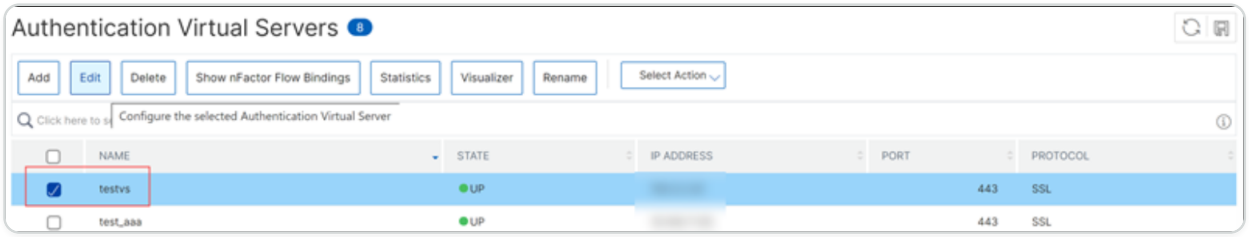
Scenario 1: LDAP group extraction as the first factor followed by LDAP or Client certificate authentication based on group membership as the second factor

In this scenario, admins can:

1. Configure LDAP group extraction in the first factor.
2. Based on the groups extracted during the first factor, admins can configure the next factors with LDAP or certificate authentication.

On the latest visualizer:

1. Navigate to **Security > AAA-Application traffic > Virtual Servers**.
2. On the **Authentication Virtual Servers** page. select an authentication virtual server and click **Edit**. In this scenario, “testvs” is the authentication server used.

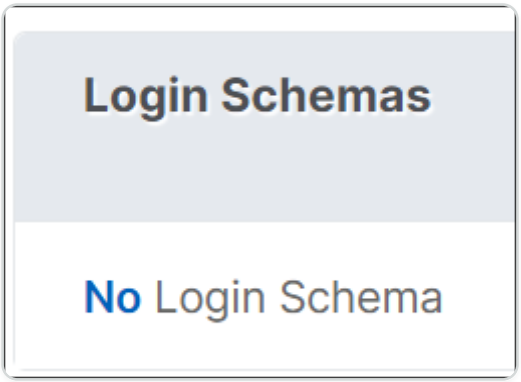


3. Create a login schema for the first factor.
   - On the **Authentication Virtual Server** page, navigate to the **Login Schemas** section.

NOTE:

In this scenario, “OnlyUsername.xml” is used as the login schema for the first factor.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

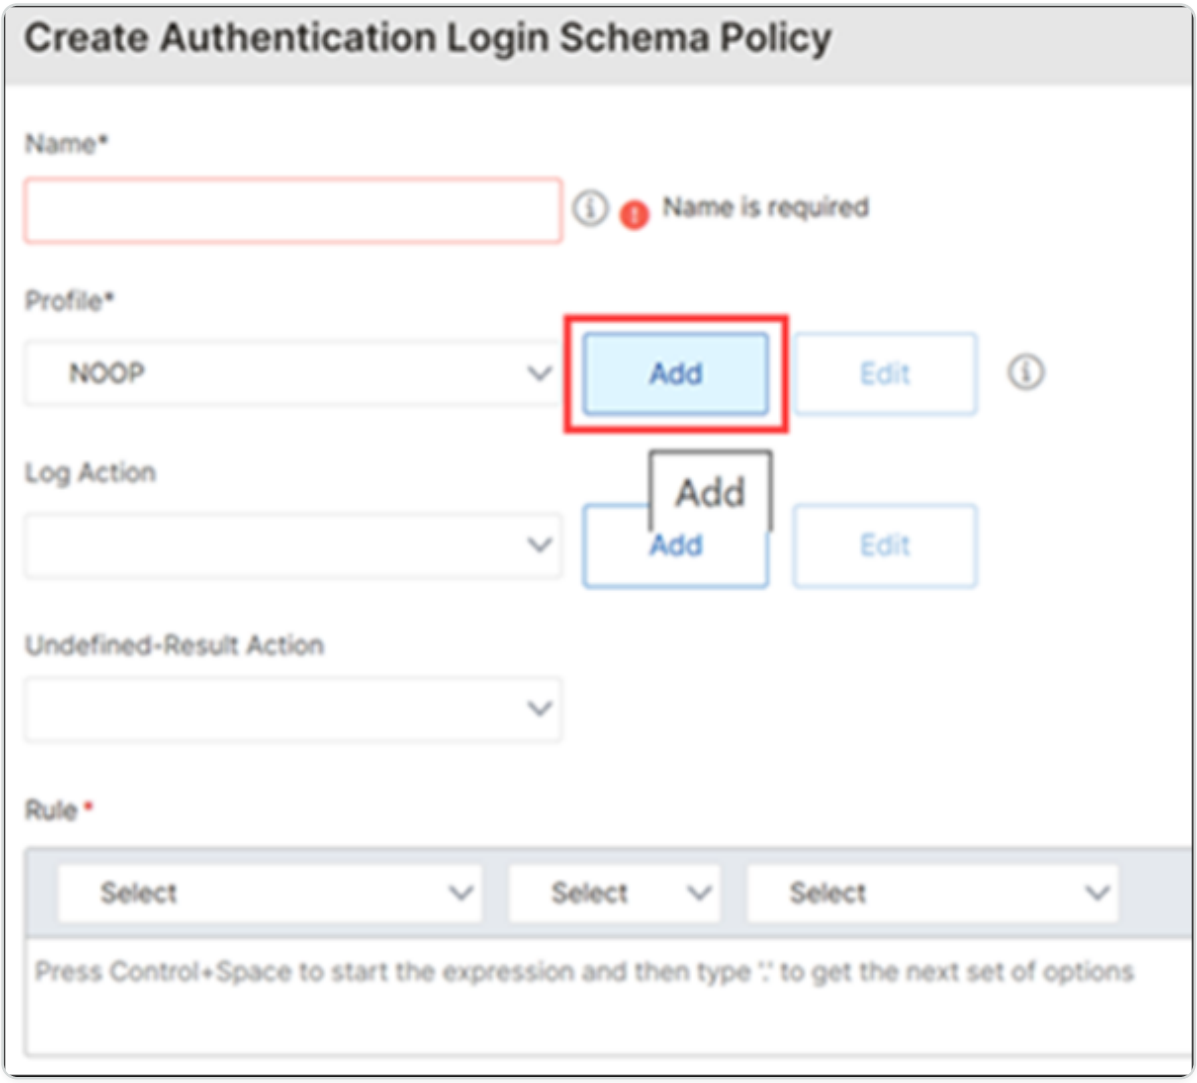


4. On the **Policy Binding** page, add a login schema policy and profile.

   - To add a policy, on the **Policy Binding** page, click **Add** next to the **Select Policy** field.

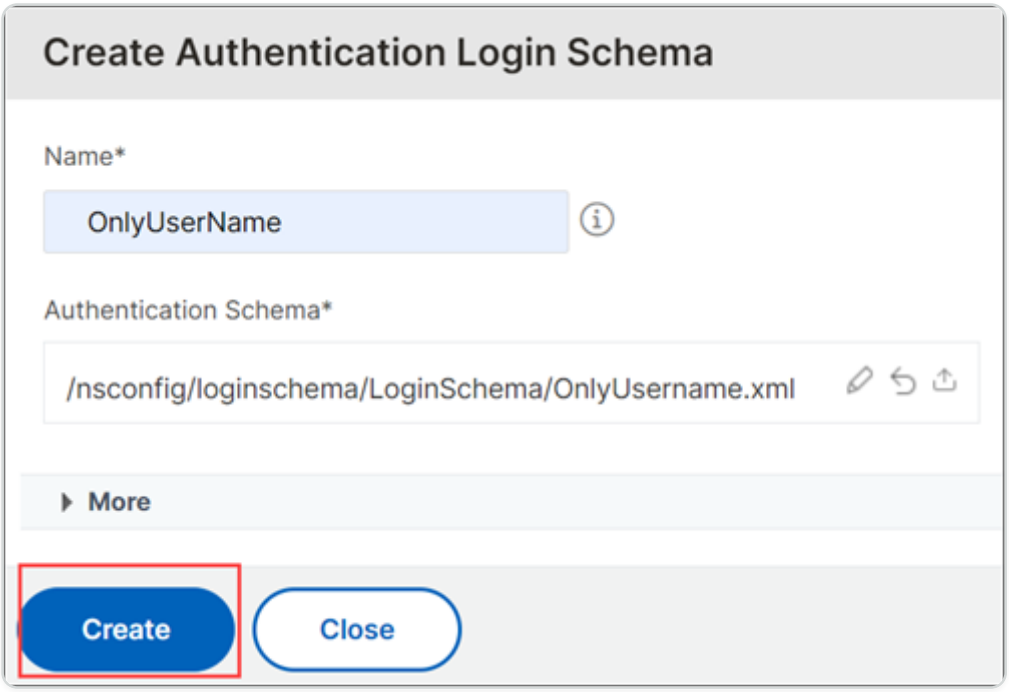
   - To add a profile, on the **Create Authentication Login Schema Policy** page, click **Add** next to the **Profile** field.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



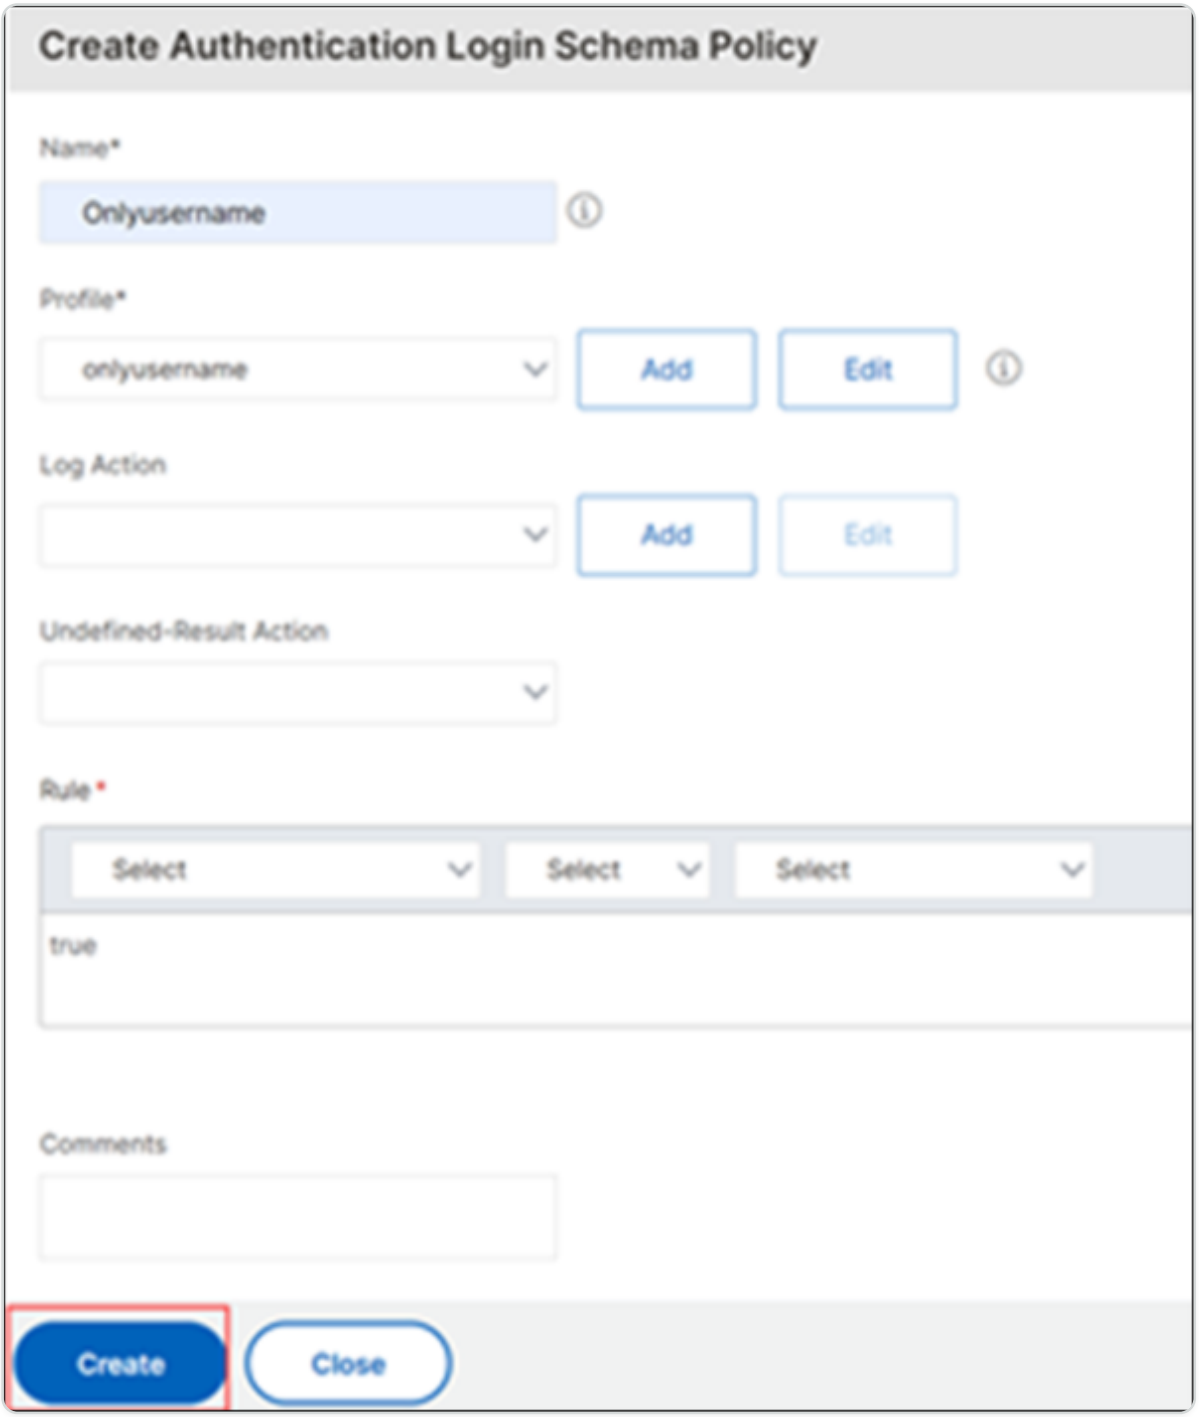
- On the **Create Authentication Login Schema** page, select “OnlyUsername” as the login schema.
- Click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- On the **Create Authentication Login Schema Policy** page, click **Create**. The authentication login schema policy and the authentication login schema are now created.

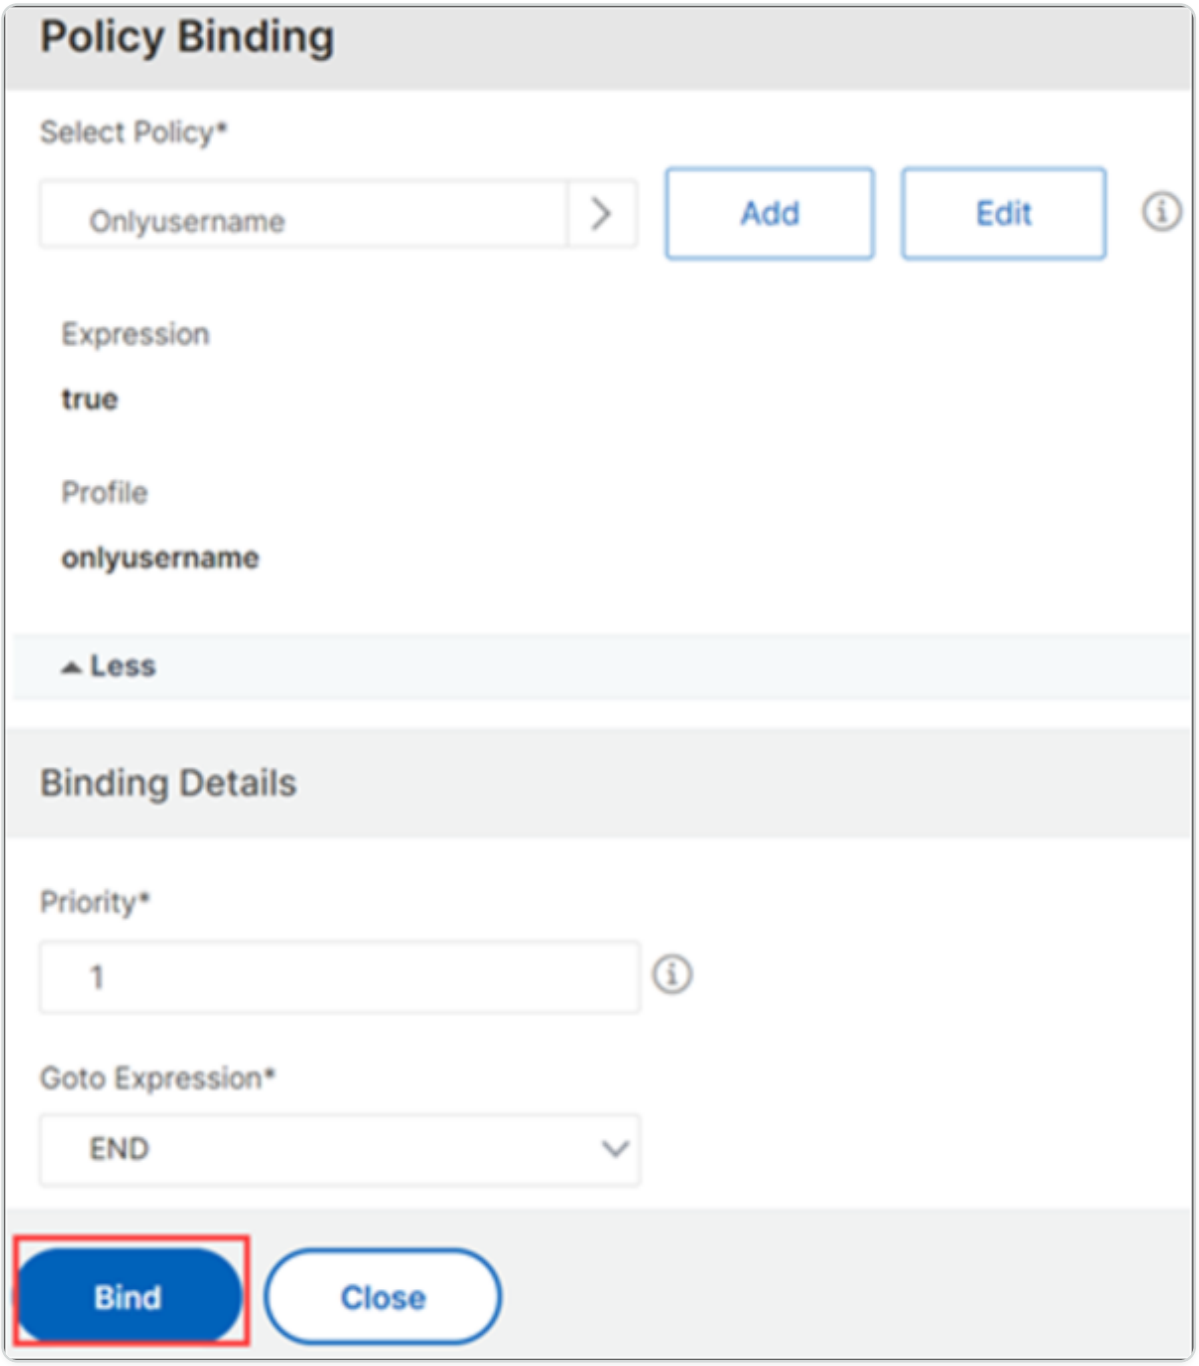
© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Bind the authentication login schema policy.

   - On the **Policy Binding** page, select the configured authentication login schema policy, configure the binding details, and click **Bind**.

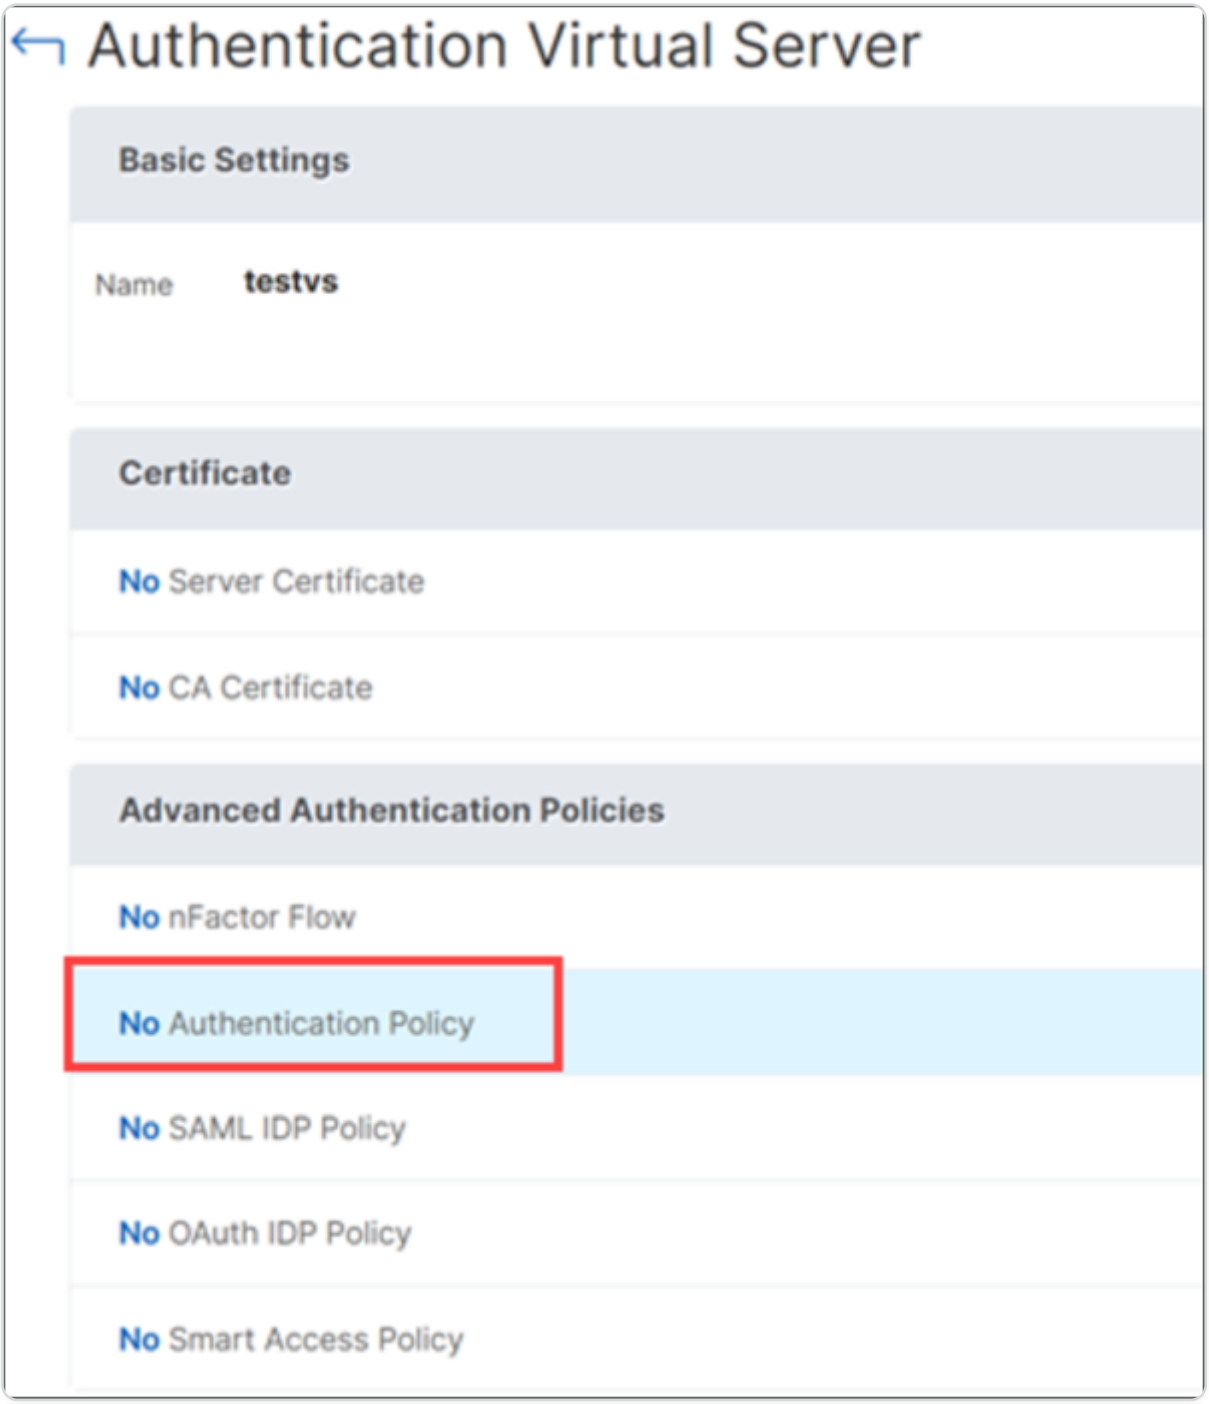
© 1997–2026 Citrix Systems, Inc. All rights reserved.



6. Create the first factor.

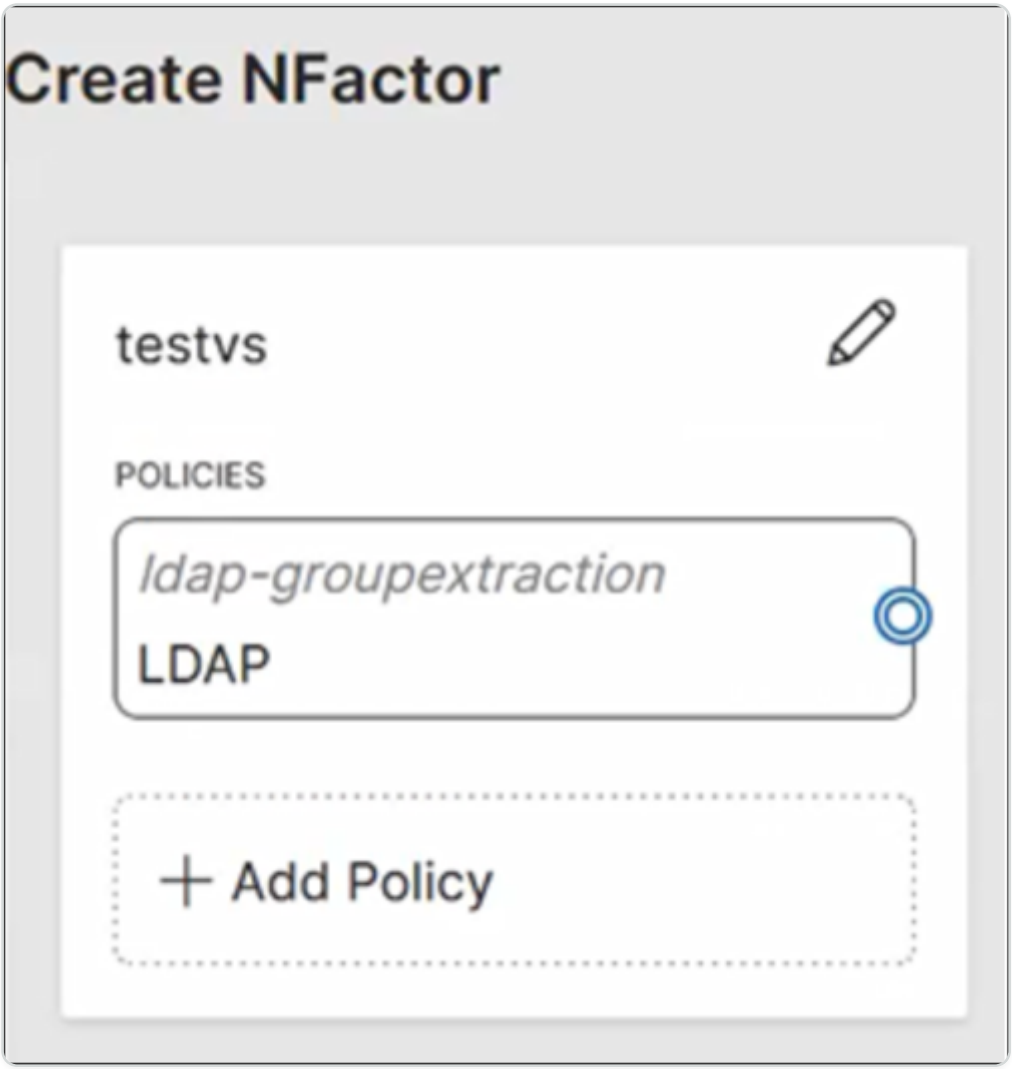
   - On the **Authentication Virtual Server** page, navigate to the **Advanced Authentication Policies** section and select the authentication policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



- On the **Create NFactor** page, configure the LDAP group extraction policy for the first factor.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

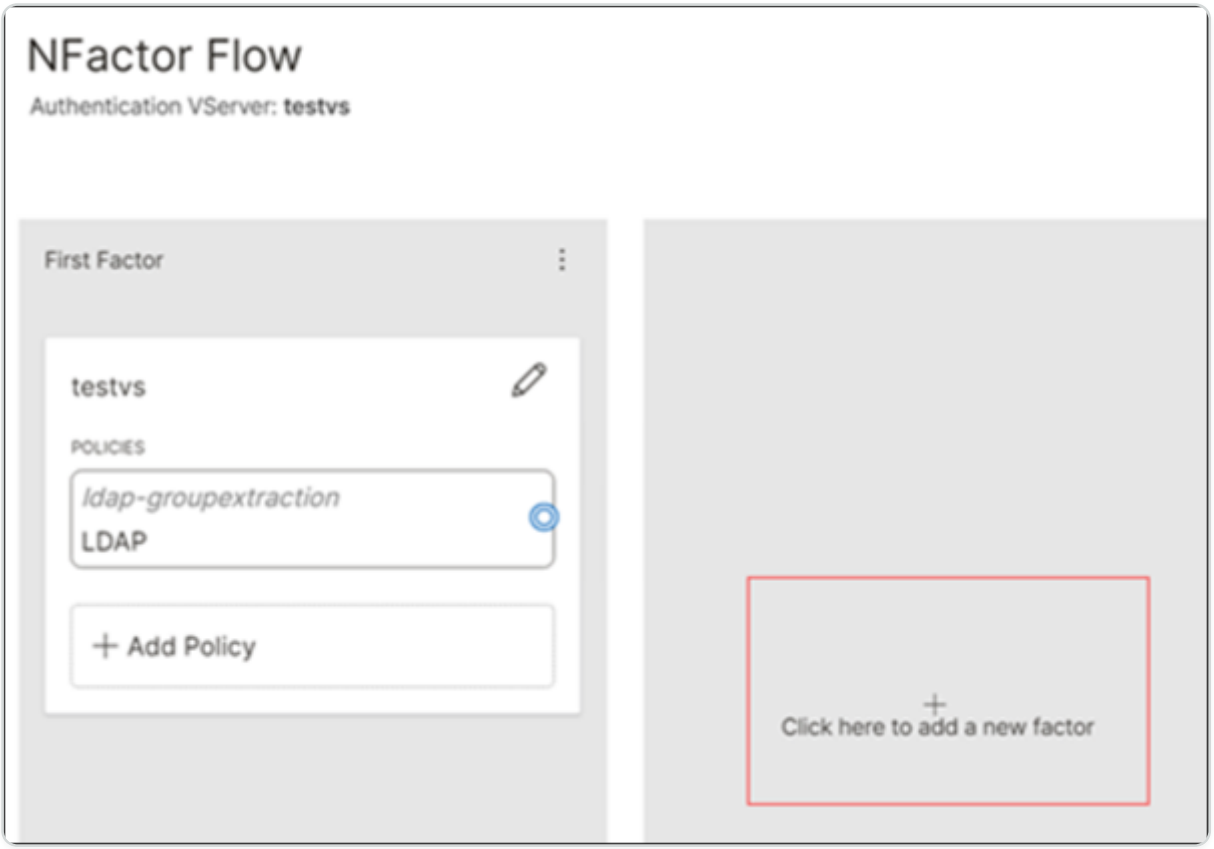


7. Click **+** to add the second factor.

NOTE:

The second factor is for the pass-through. This means that there is no login schema for this factor. Configure 2 policies (LDAP and certificate policies) for 2 different user groups for authentication. If the rules configured for this policy are met, NetScaler® does not perform any authentication for this factor.

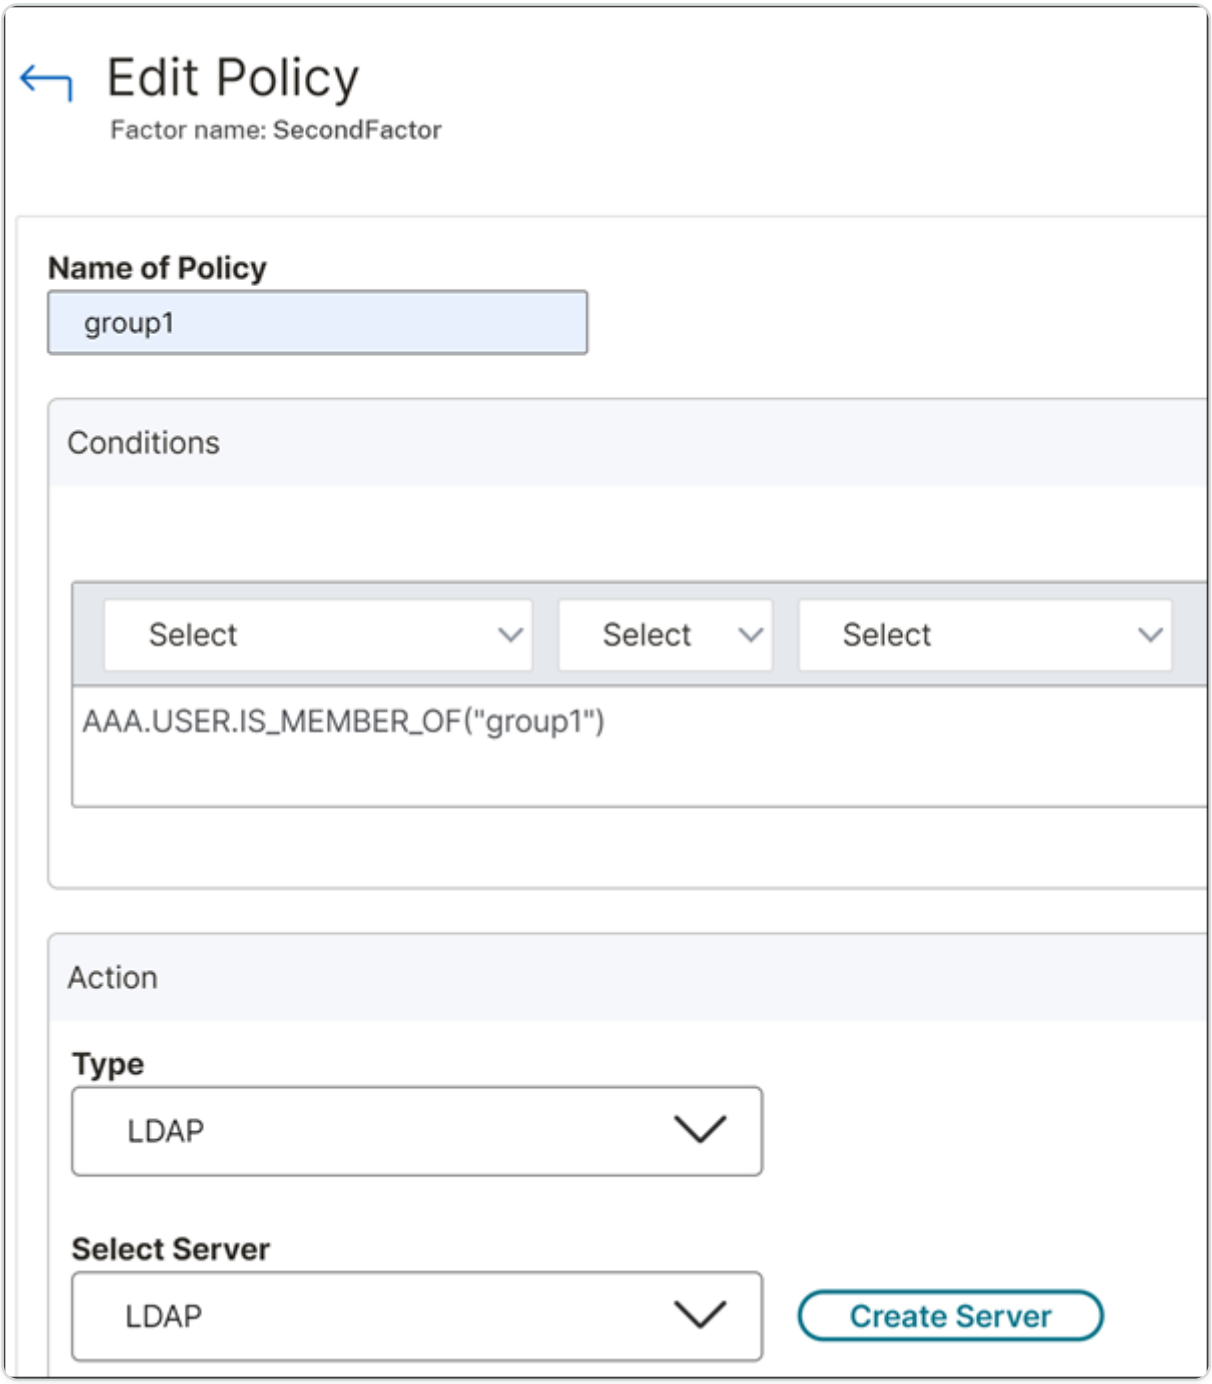
© 1997–2026 Citrix Systems, Inc. All rights reserved.



- Configure policies for different user groups. In this scenario, based on the groups extracted in the first factor, you can determine the second factor as LDAP or certificate-based authentication.

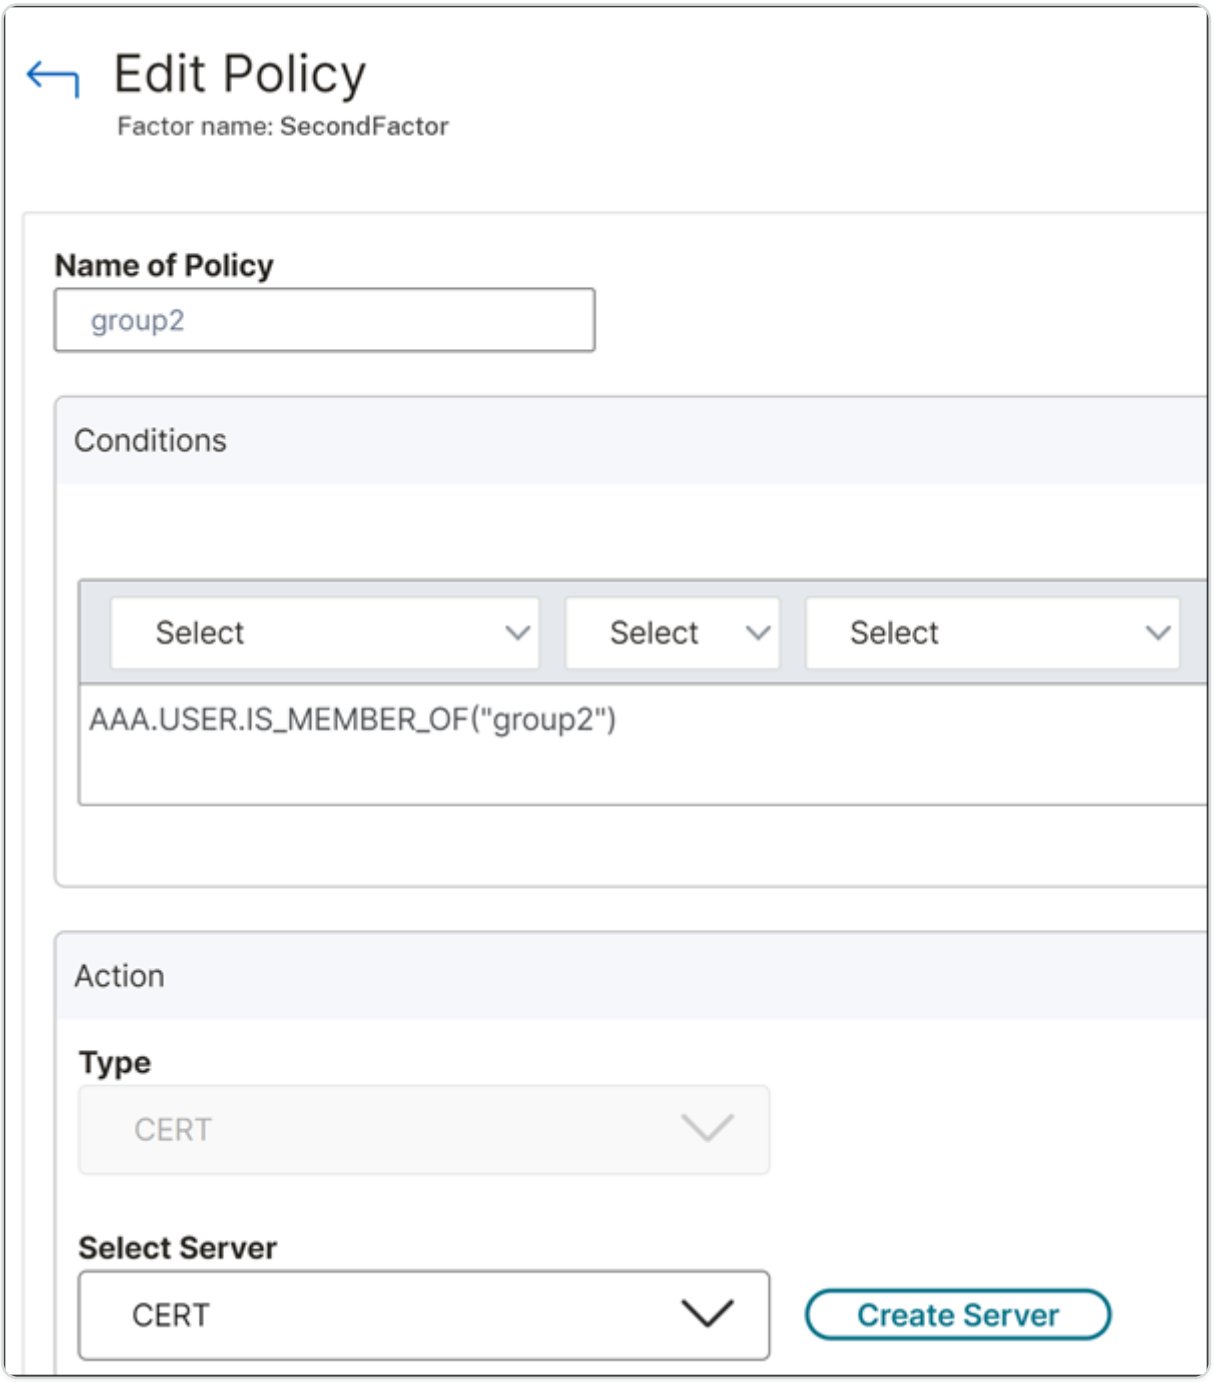
The following screenshot displays the policy expression and server details (LDAP) for “group1” users.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



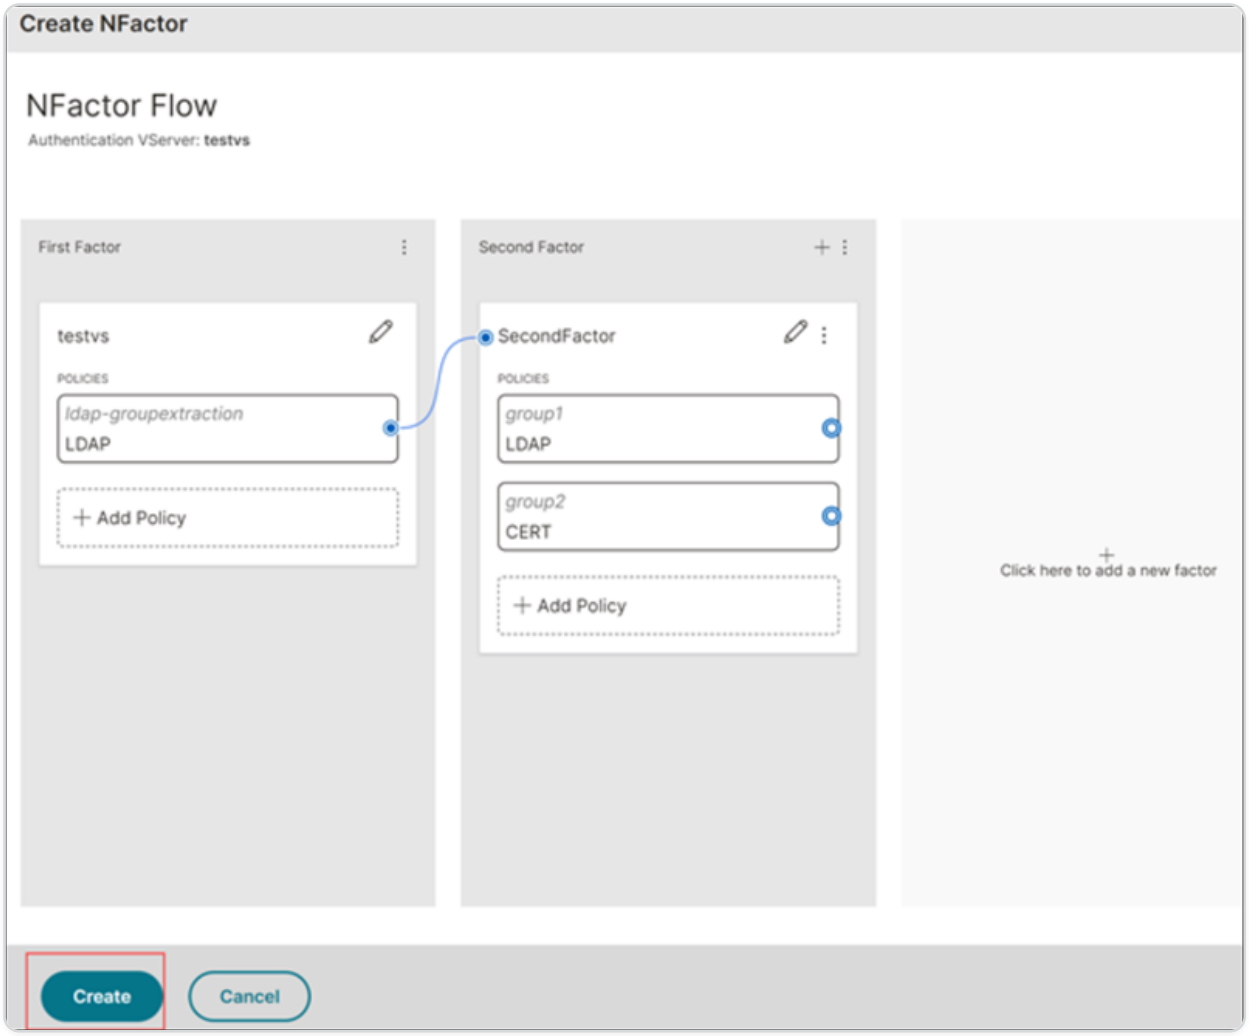
The following screenshot displays the policy expression and server details (certificate-based authentication) for “group2” users.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



8. On the **Configure Factor** page, click **Add**.
9. On the **NFactor flow** page, link the first and second factors using the blue dots and click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



10. Click **Done**.

Scenario 2: Domain drop-down list as the first factor followed by different policy evaluations based on the domain selection

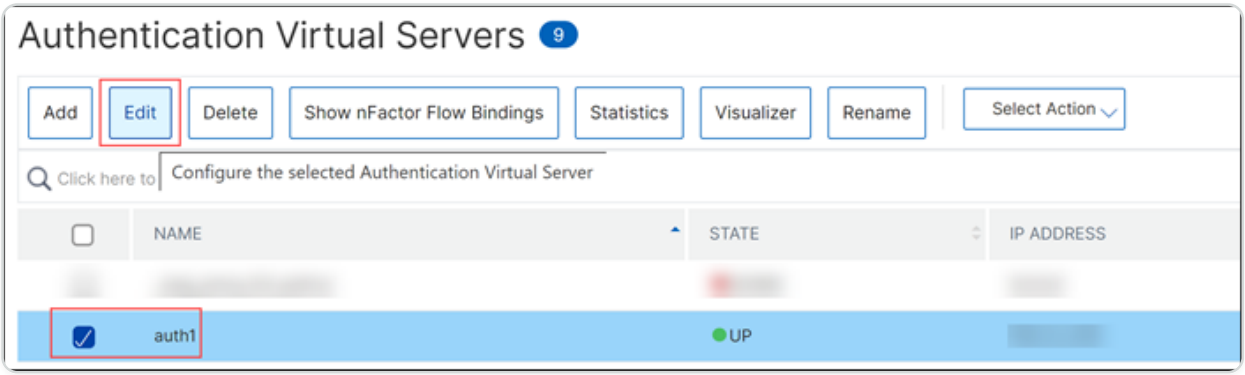
In this scenario, admins can:

1. Configure the Azure EntraID and AD credentials for users of domain-type Employee.
2. Configure the Google IdP and AD credentials for users of domain-type Partner.
3. Configure the Okta and AD credentials for users of domain-type Vendor.

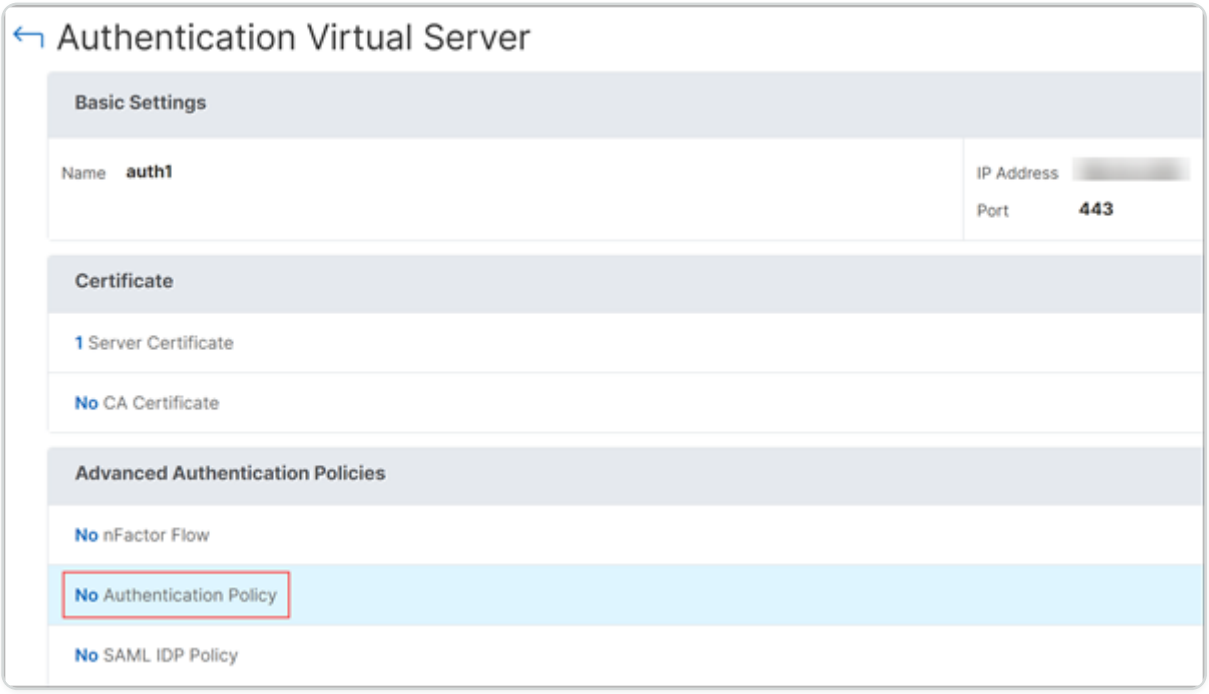
On the latest visualizer:

1. Navigate to **Security > AAA-Application traffic > Virtual Servers**.
2. Select the authentication virtual server for the nFactor flow and then click **Edit**. In this scenario, "auth1" is the virtual server for which the nFactor flow is created.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



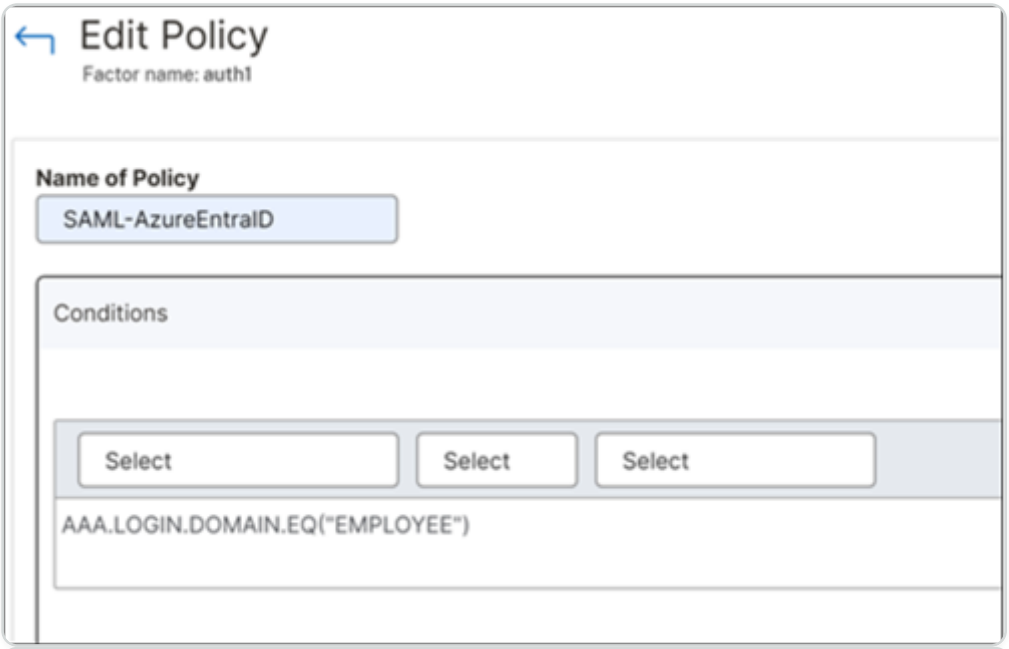
3. Under **Advanced Authentication Policies**, select an authentication policy.

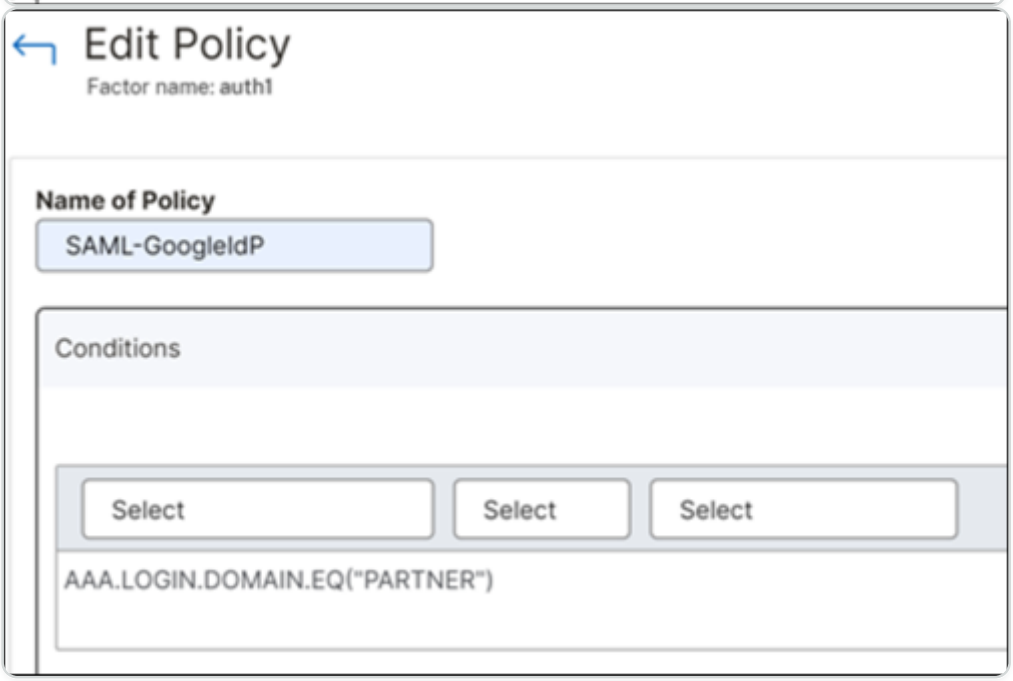


4. On the **First Factor** tile, configure SAML policies.

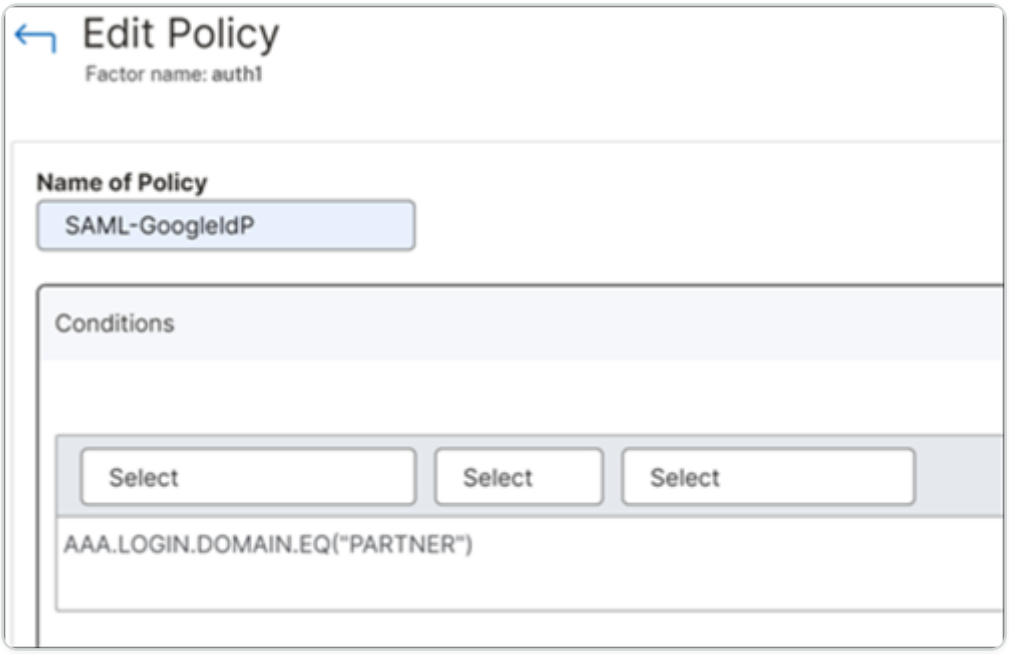
   - In this scenario, for the first factor, the policy expressions are configured for users of 3 different domains; Employee, Partner, and Vendor.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

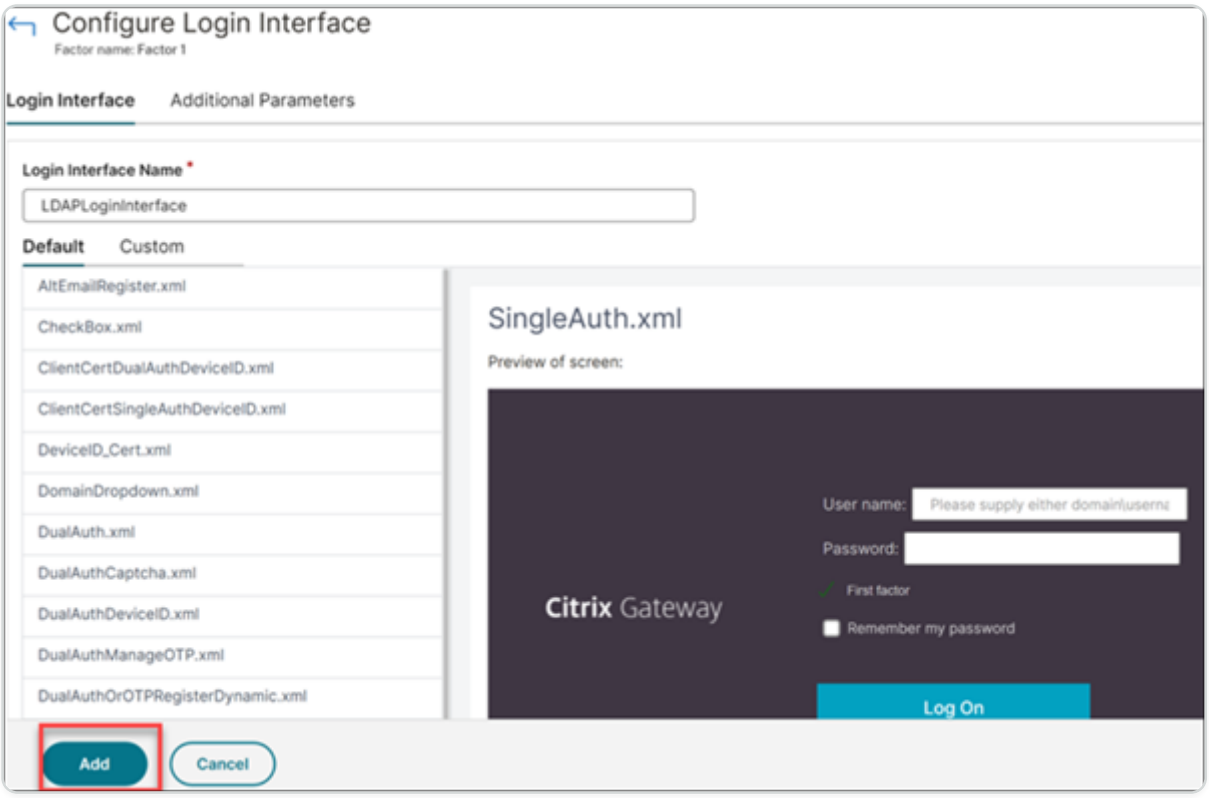




© 1997–2026 Citrix Systems, Inc. All rights reserved.

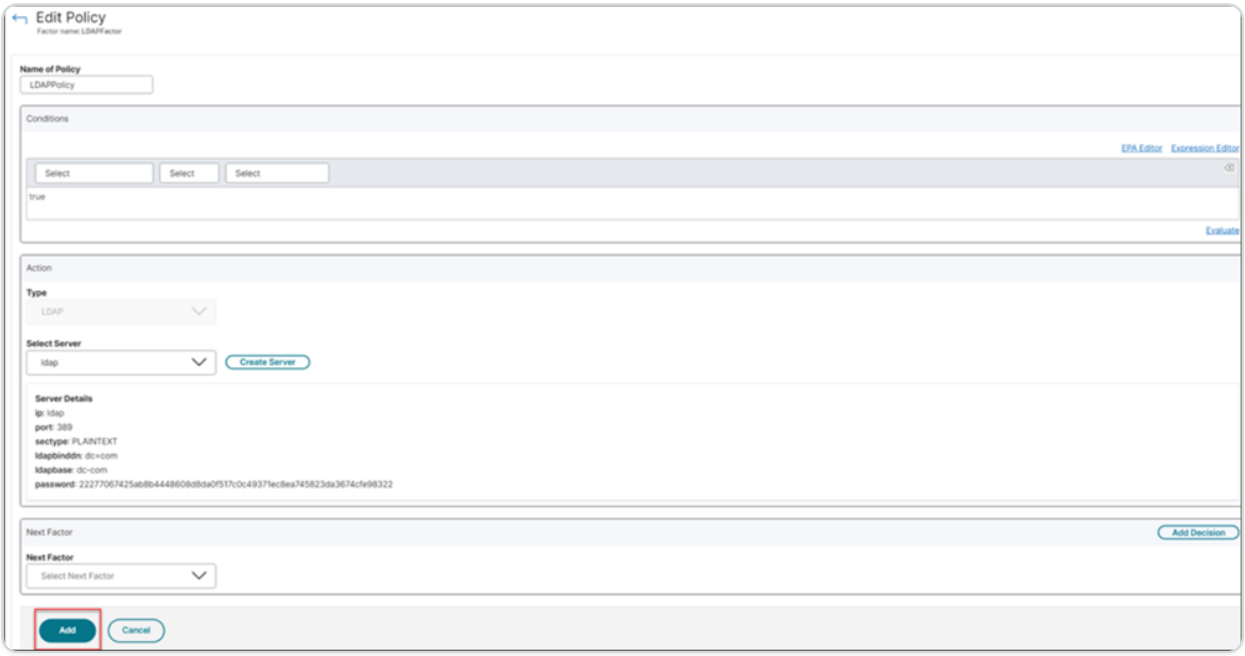


5. On the **Second Factor** tile, configure the login interface and click **Add**.

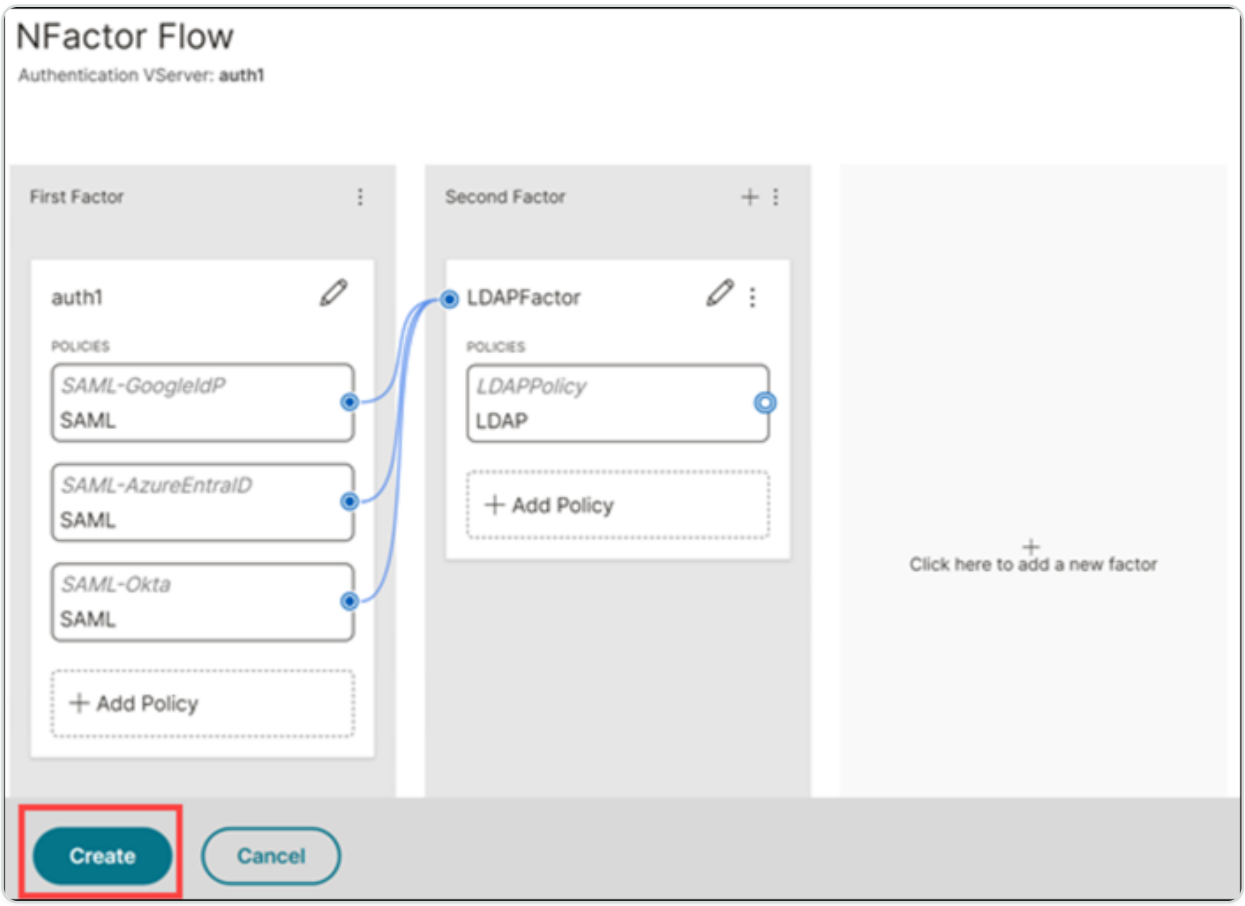


6. Configure the LDAP policy and click **Add**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



7. Link both the factor tiles and click **Create**.



nFactor visualizer for simplified configuration

Starting from NetScaler release 13.0 build 36.27, nFactor configuration through the GUI is simplified by using the nFactor Visualizer. The nFactor Visualizer helps admins add multiple factors without losing track of each factor. The group of factors that are built in the flow are displayed in

© 1997–2026 Citrix Systems, Inc. All rights reserved.

one place. Admins can add authentication success and failure paths separately. After creating the flow, admins have to bind the nFactor flow to an authentication virtual server.

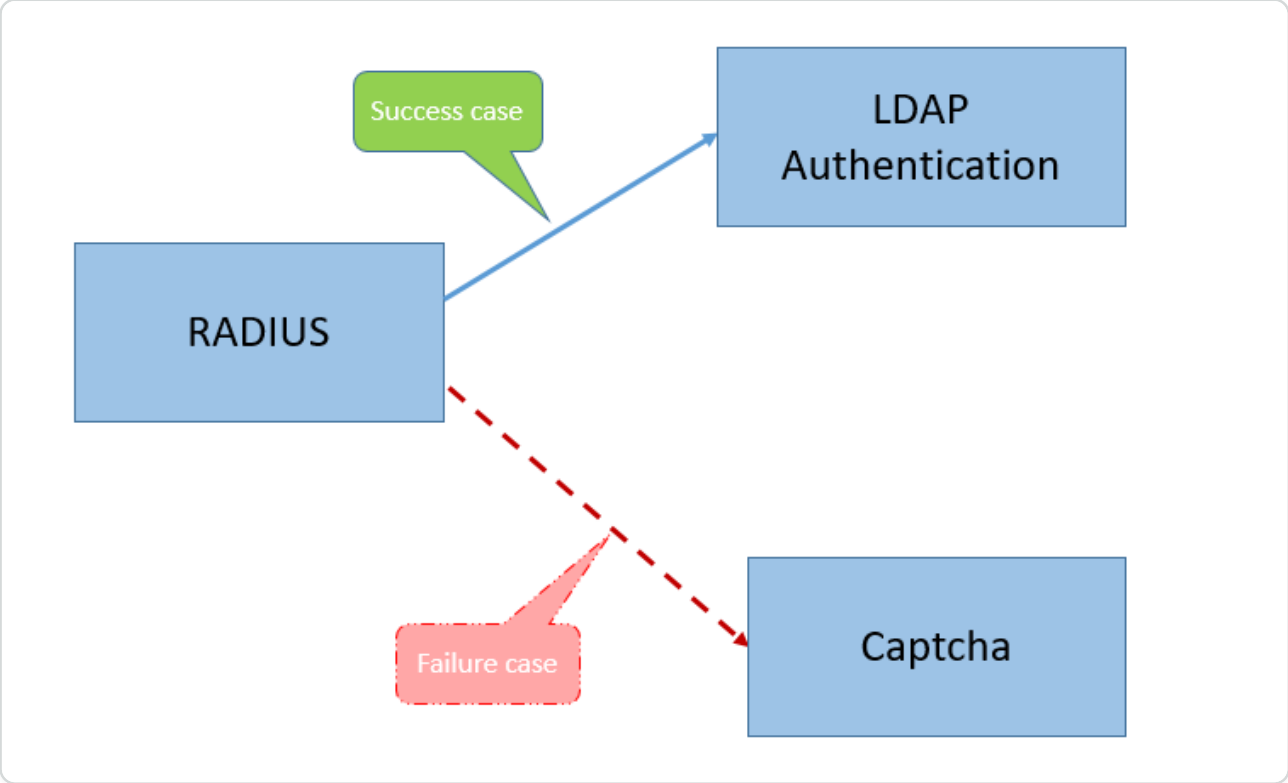
NOTE

- The visualizer described in this article is planned for deprecation.
- All factors created by an admin in the nFactor flow are retained for any future use.
- From NetScaler feature release 13.0 build 64.35 and above, using the nFactor visualizer, you can start the nFactor flow with a decision block.

Previously, nFactor configuration was cumbersome wherein the admins had to visit many pages to configure it. If a change was required, the admins had to revisit the configured sections each time. Also, there was no option to view the complete configuration in one place.

Use Case 1: RADIUS followed by LDAP authentication, else fallback to Captcha through nFactor Visualizer

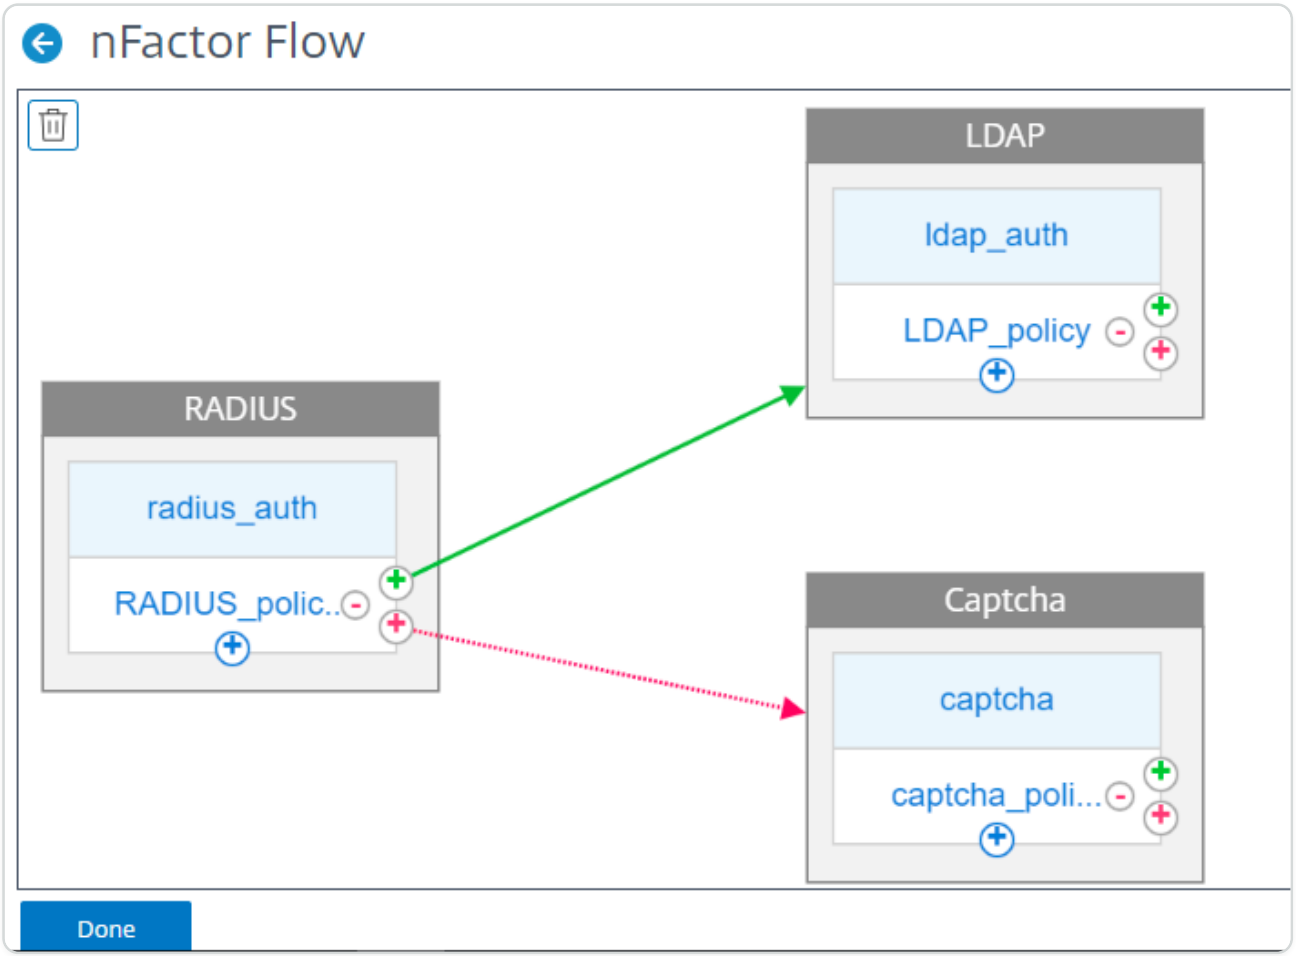
Achieve RADIUS authentication as the first-level authentication followed by LDAP authentication. In case RADIUS fails, authentication must fall back to Captcha.



To achieve this use case, you can use the nFactor Visualizer. The Visualizer provides various controls that can be used to add this flow and the related items.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following figure displays the nFactor flow created for the previous mentioned use case by using the visualizer.

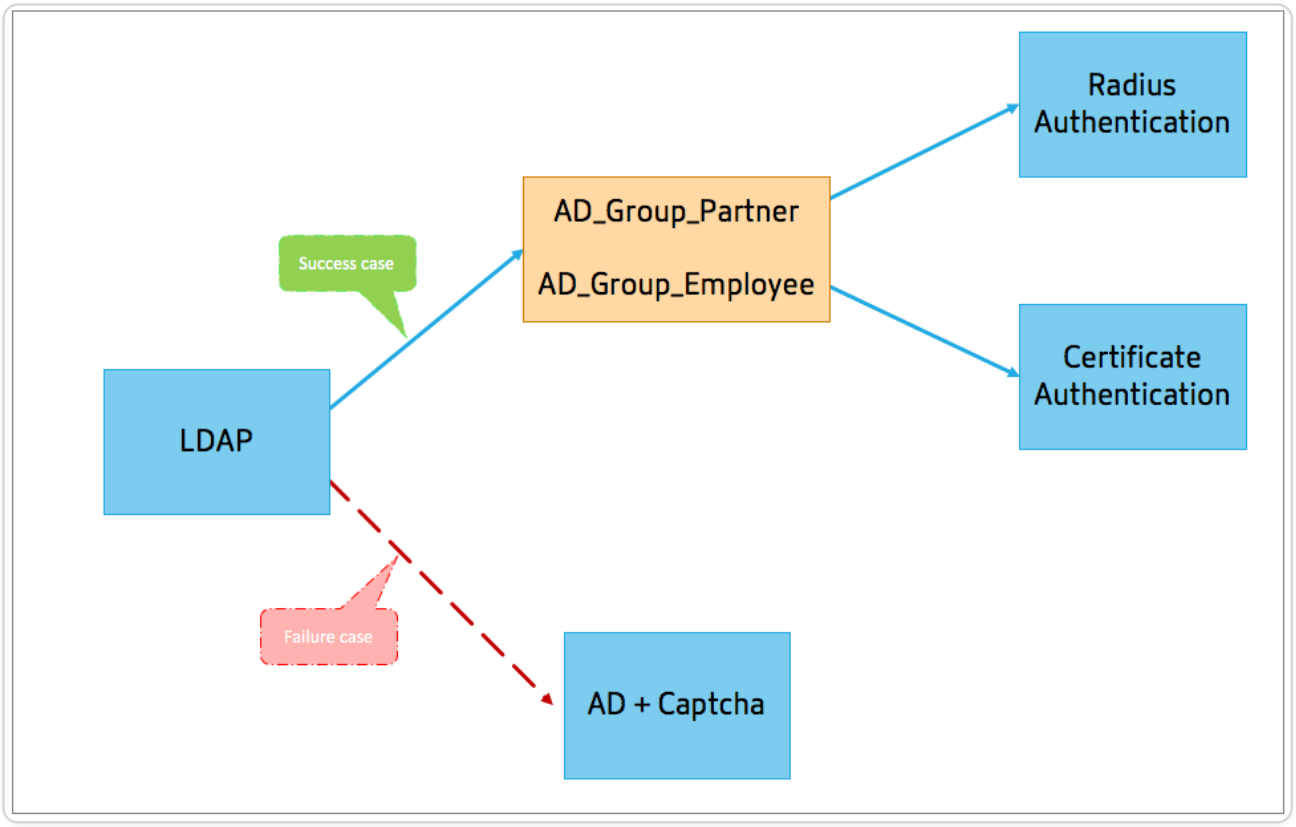


- **RADIUS.** You configure RADIUS as the first factor. You add a login schema and a policy. In this example, radius_auth and RADIUS_policy are the login schema and policy that is added. For the RADIUS_Policy, you can add another factor for the success case. In this example, an LDAP factor block is added for the success case. For the failure case, you can add a Captcha factor.
- **LDAP.** You configure LDAP authentication as the second factor. You add a login schema and a policy. In this example, ldap_auth and LDAP_policy are the login schema and policy that is added.
- **Captcha.** For the RADIUS policy failure case, you create a Captcha factor. In this example, captcha and captcha_policy are the login schema and policy that is added.

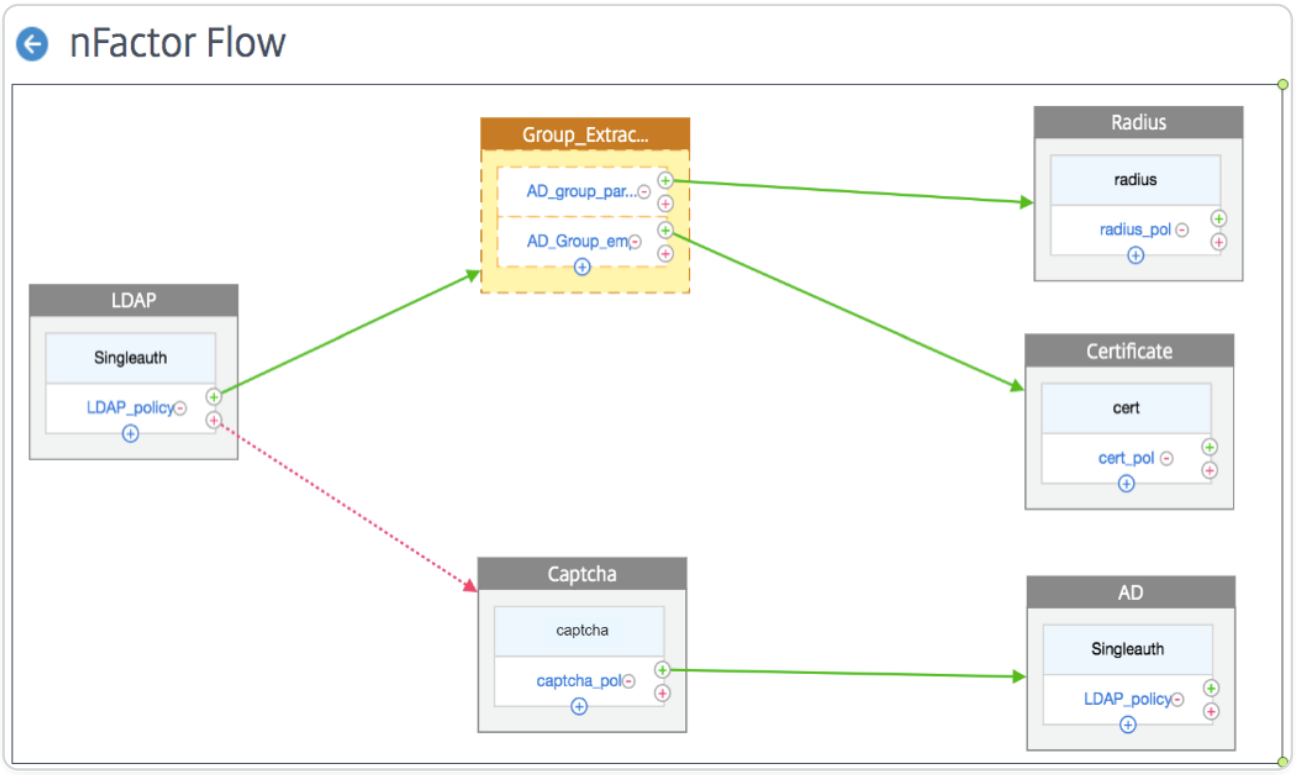
Use Case 2: LDAP followed by RADIUS/Certificate authentication with Captcha based on LDAP Group Membership through nFactor Visualizer

Achieve RADIUS authentication as the first-level authentication followed by LDAP authentication. In case RADIUS fails, authentication must fall back to Captcha.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



The following figure displays the nFactor flow created for the previous mentioned use case by using the visualizer.



- **LDAP.** You configure LDAP as the first factor. You add a login schema and a policy. In this example SingleAuth and LDAP_Policy are the login schema and policy that is added. For the LDAP_Policy, you can add another factor for the success case. In this example, a decision

© 1997–2026 Citrix Systems, Inc. All rights reserved.

block is added for the success case. For the failure case, you can add Captcha followed by AD factor.

- **Group Extraction LDAP.** Is the decision block added for the LDAP success case. The decision block is used as a branch out factor to branch out the users based on the policy rules. Visualizer allows configuring only a NO_AUTHN policy for the decision block.

  In this example, Group_Extraction_LDAP is the decision block. You add two policies (`AD_Group_Partner and AD_Group_Employee`) to this decision block. As explained in the use cases, all requests routed through AD_Group_Partner policy use RADIUS authentication. Therefore, you connect the success case of this policy to the next factor that is RADIUS factor. Similarly, all requests routed through AD_Group_Employee policy use certification authentication. Therefore, you connect the success case of this policy to the next factor that is the certification authentication factor.

  - **RADIUS.** For the AD_Group_Partner policy success case, you create the RADIUS authentication factor.
  - **Certificate.** For the AD_Group_Employee policy success case, you create the certificate authentication factor.

- **Captcha.** For the LDAP policy failure case, you create two next factors, Captcha and AD factor.

NOTE

- If you have a use case to branch out as a first thing, then you can either create two flows and bind separately or create one flow with the first one as branch out, and bind it to the virtual server.
- If you have multiple blocks, and to view the entire flow in the nFactor Flow screen, click the visualizer and drag the flow to the extreme left.
- We recommend that you modify the nFactor flows using the nFactor Flows page only.

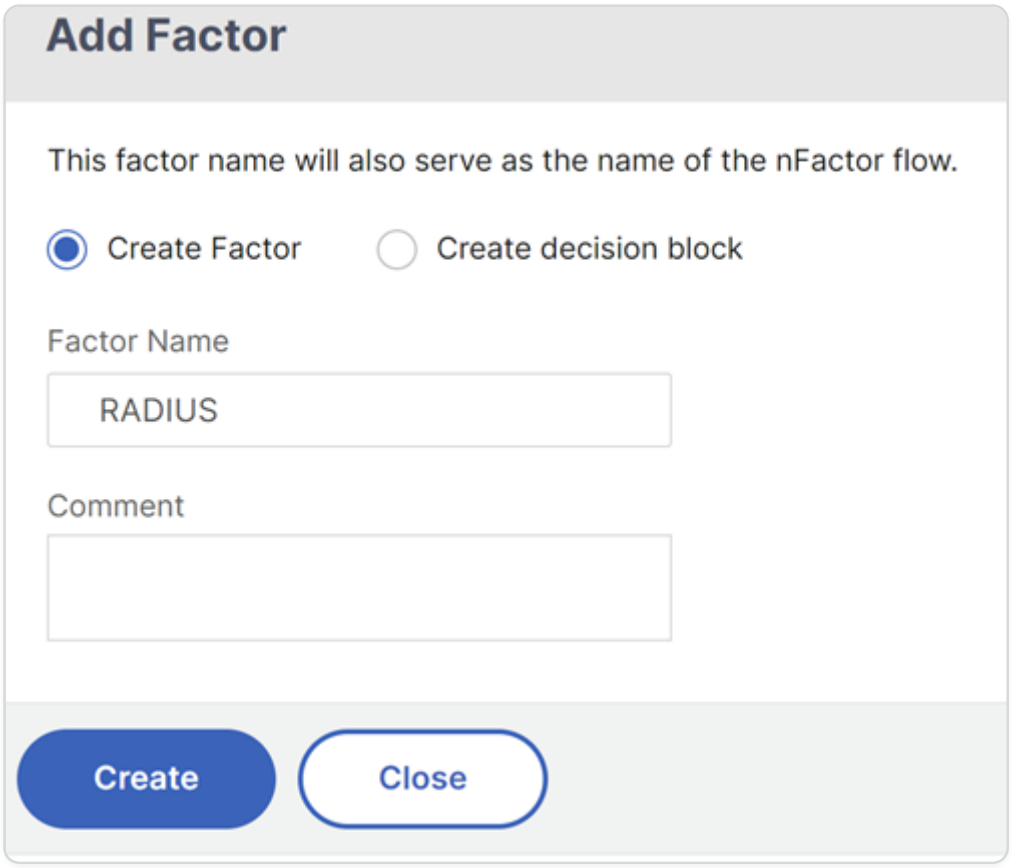
To configure nFactor by using the nFactor Visualizer

NOTE

The following nFactor configuration is a simple example that helps you accomplish the Use Case 1 scenario configurations.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Navigate to **Security > AAA – Application Traffic > nFactor Visualizer > nFactor Flows**.
2. Click **Add**.
3. On the **nFactor Flows** page, click **+** to add a first factor for the flow. The first factor also serves as an identifier for this nFactor flow.
4. Enter the factor name and click **Create**.



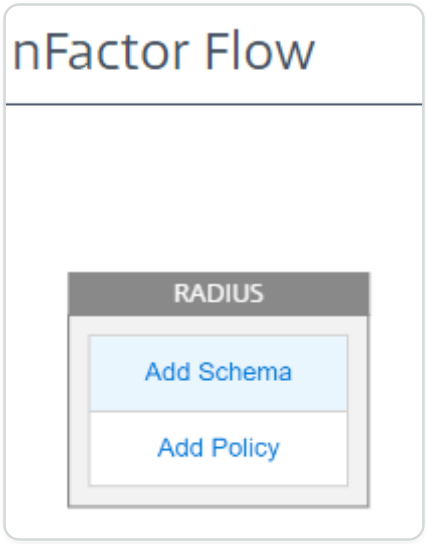
The factor name appears on the factor block in the nFactor Flow page.

NOTE

We recommend that you do not use policy label names such as, `__root` and `__<flow_name>` as suffix and `_db_` as prefix. It is used as the factor names that are created in the nFactor flow.

5. Once the RADIUS factor is created, the Add Schema and Add Policy must be created.

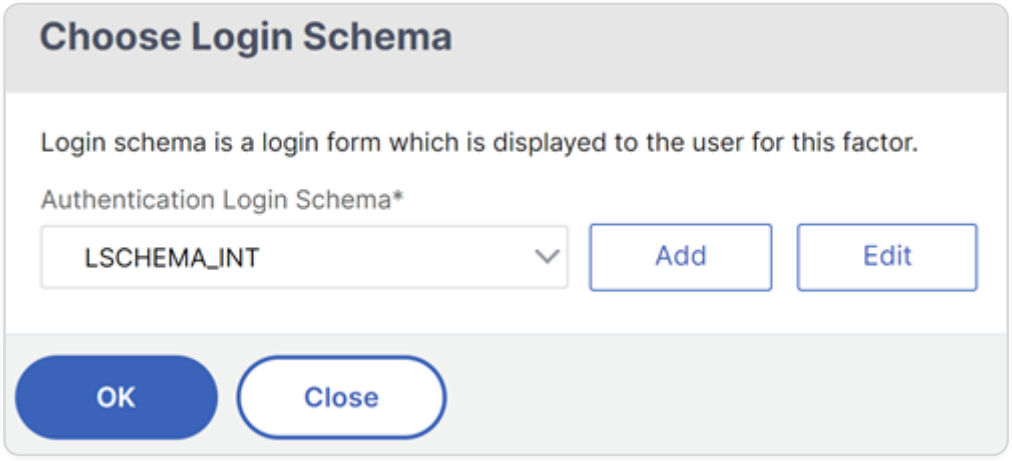
© 1997–2026 Citrix Systems, Inc. All rights reserved.



NOTE

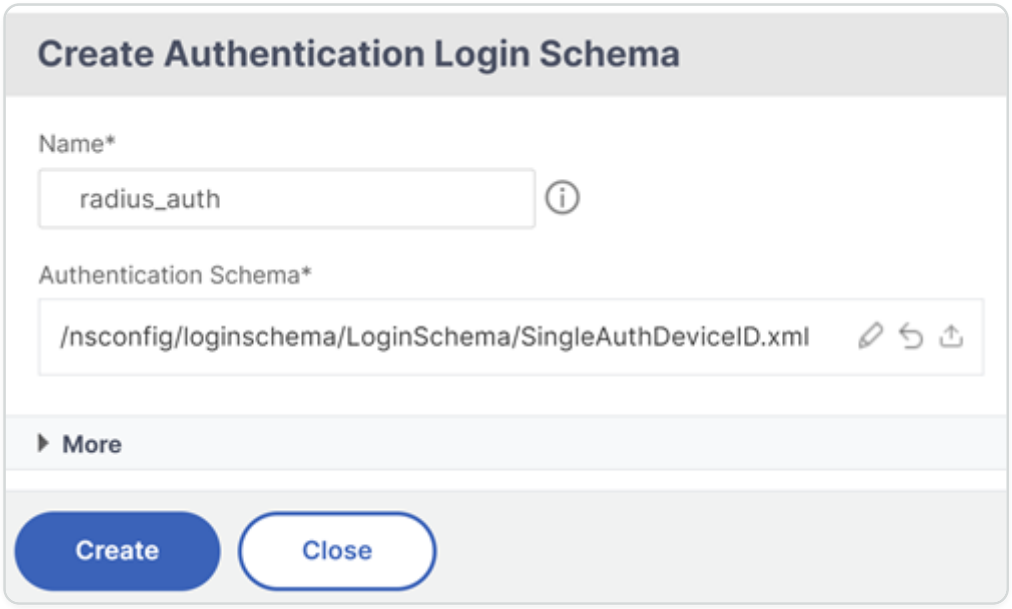
For more information, see nFactor concepts, entities, and terminology.

6. Click **Add Schema**. You can either add a new login schema or select an existing login schema from the **Authentication Login Schema** list.

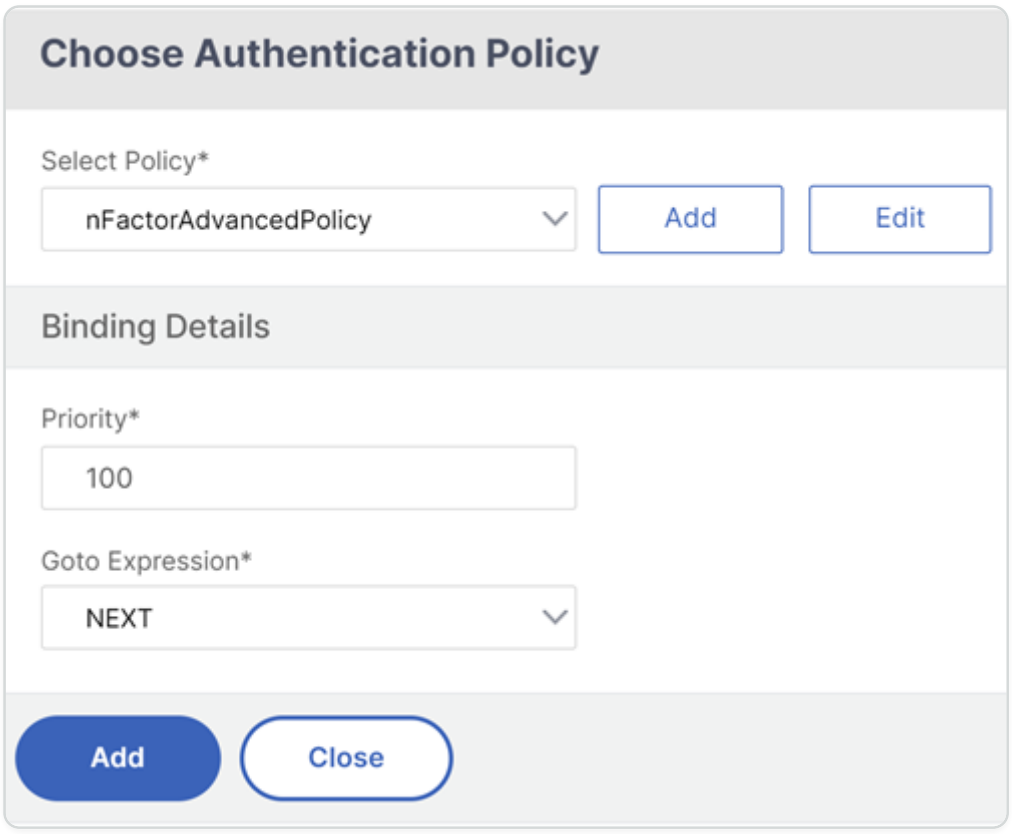


7. To create a login schema, click **Add** and in the **Create Authentication Login Schema** page, enter the name for the schema. Click **Edit** (pencil icon) to select the **Login Schema Files** from the list.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

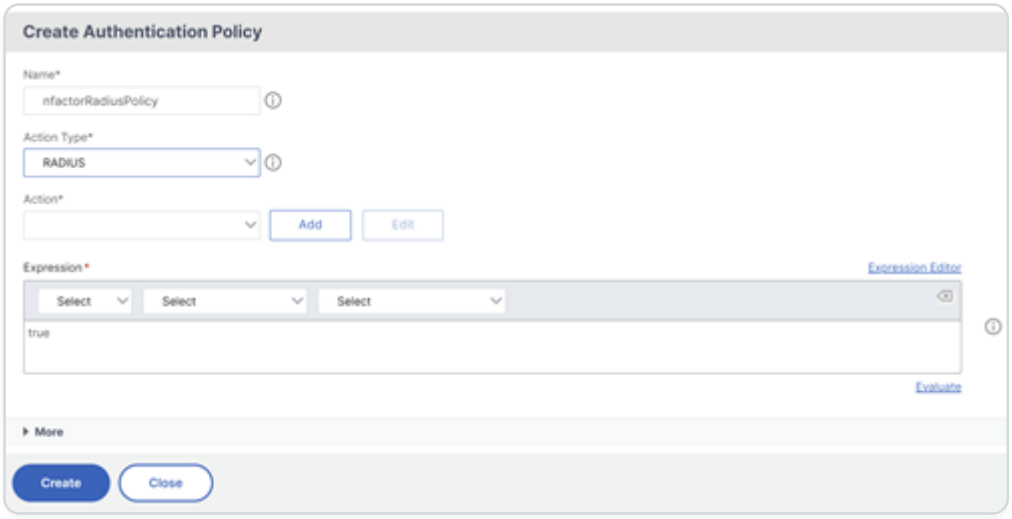


8. Click **Add Policy**. You can either create a new policy or choose an existing authentication policy.

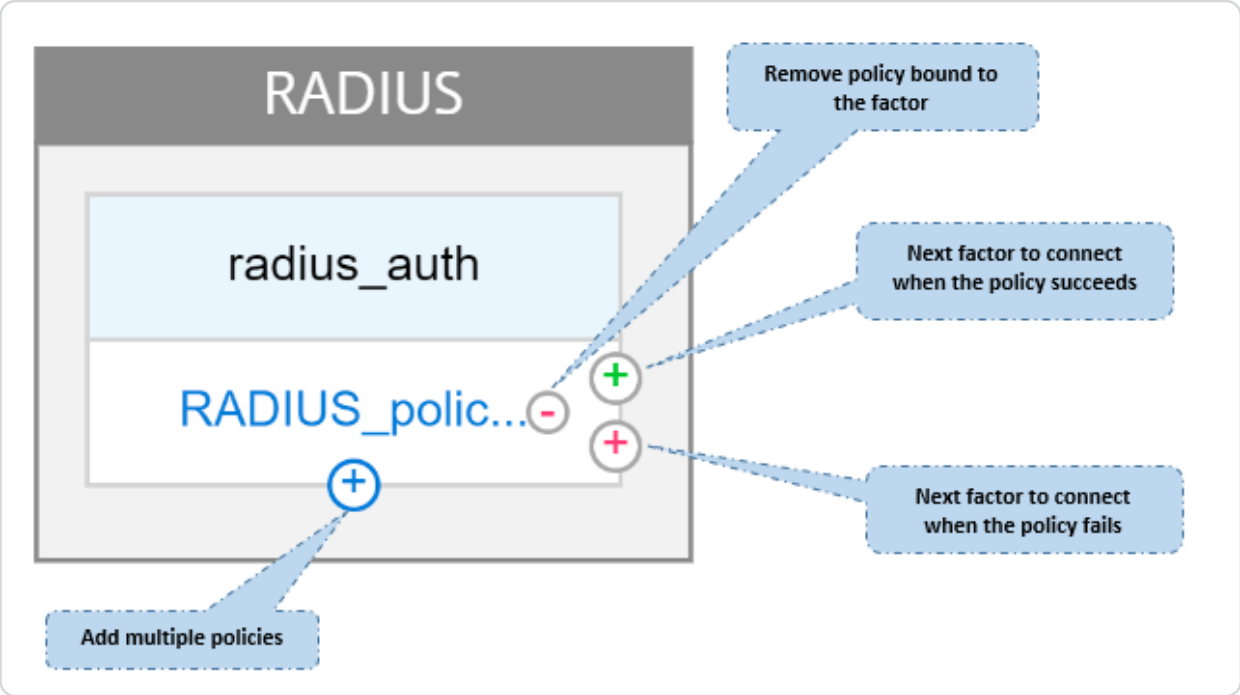


9. To create a new policy, click **Add** and in the **Create Authentication Policy** page, enter the name for the policy and click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



10. After you add a login schema and policy to the factor, the login schema and policy appear on the factor in the Visualizer as displayed in the following figure. For any given factor, you can add multiple policies and define the next factor for the success and failure of each policy. You can also remove the policies that are part of the factor.



11. After you create the flow, you can then bind the nFactor flow to an authentication virtual server.

Adding the next factor

To add the next factor, you can select one of the following options as per your requirement:

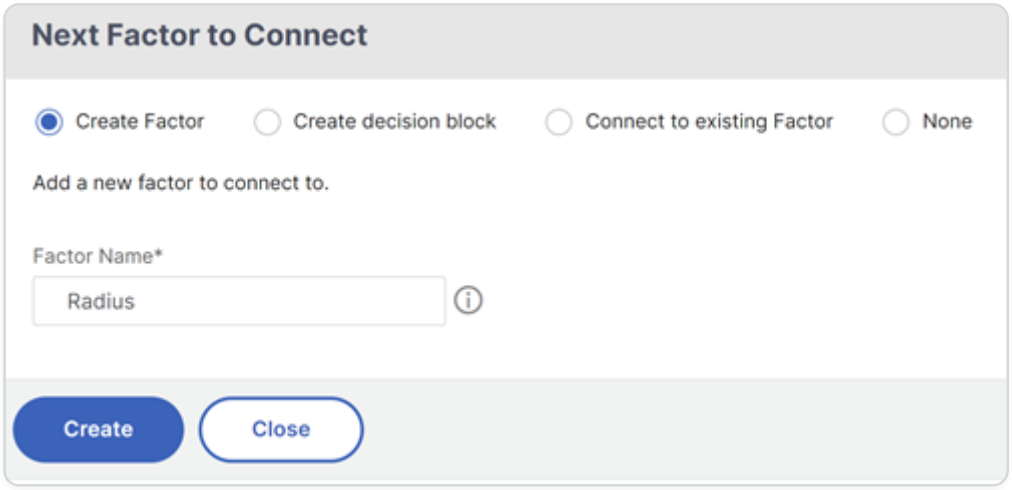
- **Create Factor**. Create a factor. Each factor that is created in a flow is exclusive to that flow.
- **Create a decision block.** Create a decision block to serve as a branch-out factor. You cannot add a login schema to the decision block. Visualizer allows configuring only a NO_AUTHN policy for the decision block.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

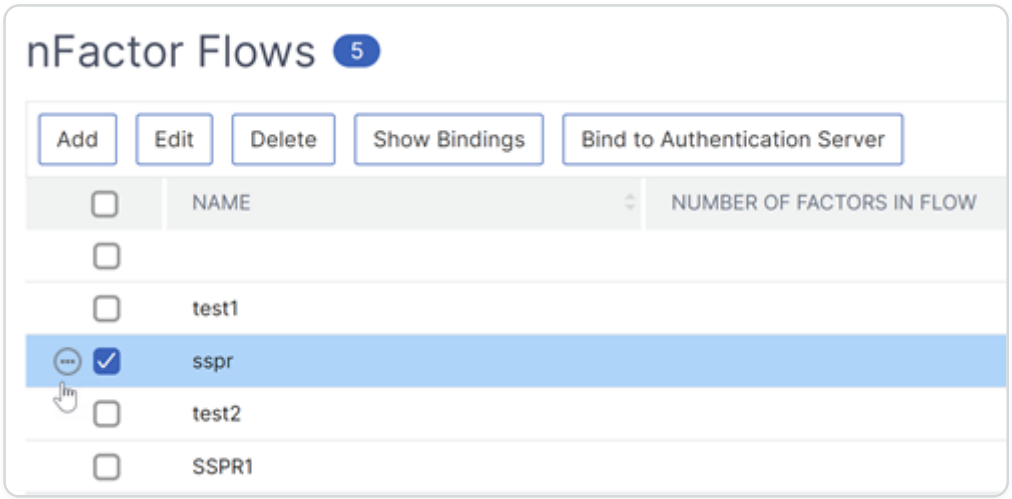
You can only add or edit the decision block through the NetScaler GUI. There is no option to configure the decision block from the CLI command.

- **Connect to an existing Factor**. Select an existing factor as your next factor. All the factors that appear in the existing list are created exclusively for that flow.
- **None.** Remove an existing connection.



To bind the nFactor flow to authentication server

1. On the **nFactor Flows** page, select an nFactor flow that you prefer to bind to an authentication virtual server.
2. Click the horizontal ellipsis and select **Bind to Authentication Server** or on the **nFactor Flows** page, click **Bind to Authentication Server**.



3. On the **Bind to Authentication Server** page, you can perform the following actions:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To add a **Authentication Virtual Server**, click **Add**.
- To select an existing authentication server from the list, click **Authentication Server** field.

4. Click **Show Bindings** from the hamburger icon to view the bindings.
5. To unbind the authentication server from the specific nFactor flow, perform the following steps:
   - On the **nFactor Flows** page, click **Show Bindings** from the hamburger icon.
   - On the **Authentication Server Bindings** page, select the authentication server to unbind and click **Unbind**. Click **Close**.

For more information on nFactor authentication, see the following topics:

- Concept: Multi-Factor (nFactor) authentication.
- Workflow: How nFactor authentication works.
- Configuration: Configuring nFactor authentication.

Enhancements to the nFactor Visualizer

Starting from NetScaler release 13.0 build 41.20, the following enhancements are made in the nFactor Visualizer.

- Admins can move the created factors to the trash icon.
- View the nFactor flows in the Authentication Virtual server page.

Trash icon. Admins can only delete the nodes that have no connections. However, the underlying policies or the schemas that are created for the factor are not deleted if the factor is moved to trash.

To view the trash icon,

1. Navigate to **Security > AAA – Application Traffic > nFactor Visualizer > nFactor Flows**. You can view the trash icon on the top left corner.
2. To delete the factor, click the factor block and drag it to trash.

View nFactor flow from Authentication Virtual Server. Admins can also view the created nFactor flows from theAuthentication Virtual Server page.

To view the nFactor flow from Authentication Virtual Server page,

1. Navigate to **Security > AAA – Application Traffic > Virtual Servers**. On the **Authentication Virtual Servers** page, you can perform the following steps:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To add an authentication virtual server, click **Add**.
- To edit an existing authentication virtual server, click **Edit** option from the details pane.

2. On the **Authentication Virtual Server** page, you can view the **nFactor Flow** option under **Advanced Authentication Policies**.
3. If there is no nFactor flow bound to the virtual server, you can click **No nFactor Flow** option under **Advanced Authentication Policies** section to either add a new nFactor flow or select the existing nFactor flow from the list.

nFactor Extensibility

nFactor authentication framework provides the flexibility of adding customizations to make the logon interface more intuitive for rich user experience. You can add custom login labels, custom login credentials, customizing UI displays and so on.

With nFactor, each factor can have its own logon screen. In each logon screen you can present any information from any of the previous factors or more information that is invisible in other factors. For example, your last factor can be an informative page where the user reads the instructions and clicks continue.

Before nFactor, custom login pages were limited and customizations and needed support. It was possible to replace the tmindex.html or apply rewrite rules to change some of its behavior. However, it was not possible to achieve the underlying functionality.

The following nFactor related customizations are captured in detail in this topic.

- Customize login labels
- Customize UI to display images
- Customize NetScaler nFactor logon form

Assumptions

You are familiar with nFactor, Shell commands, XML, and text editors.

Prerequisites

- Customization described in this topic is possible only when the RfWeb UI theme (or theme based) is configured on NetScaler.
- Authentication policy must be bound to the authentication, authorization, and auditing virtual server, else the flow does not work as intended.
- You have the following items related to nFactor

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- XML schema
- JavaScript
- Authentication actions
- Authentication virtual server
- NetScaler version 11.1 and later

Customize logon labels

To customize logon labels, you need the following:

- The XML schema that describes how the logon page looks.
- The script.js file that contains the JavaScript that is used to change the rendering process.

NOTE:

The script.js file can be found in the directory `/var/netscaler/logon/themes/<custom_theme>/`.

How it works

The JavaScript parses the XML file, rendering each item inside the `<Requirements>` tag. Each element corresponds to a line in the HTML form. For example, a login field is a line, the password field is another line, and so is the logon button. To introduce new lines, you must specify them in the XML schema file using the StoreFront SDK. The StoreFront SDK allows the logon page with an XML schema to use the `<Requirement>` tag and define elements on it. These elements allow to use JavaScript to introduce in that space whatever HTML elements are required. In this case, a line is created with some text in the form of HTML.

The XML that can be used is as follows:

```
<Requirement>

<Credential>

<Type>nsg-custom-cred</Type>

<ID>passwd</ID>

</Credential>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Label>

<Type>nsg-custom-label</Type>

</Label>

</Requirement>
```

`<Requirement>`: Space provided in the logon page. The credential fills the space, and the other parts route the engine into the correct information. In this case, type `nsg-custom-cred`. This is defined as plain text and the label is defined for its body. The requirement XML is paired with the JavaScript code to achieve the required results.

```
// Custom Label Handler for Self Service Links

CTXS.ExtensionAPI.addCustomAuthLabelHandler({

getLabelTypeName: function () { return "nsg-custom-label"; },

getLabelTypeMarkup: function (requirements) {

return $("< Enter your HTML codes here>");

},

// Instruction to parse the label as if it was a standard type

parseAsType: function () {

return "plain";

}

});

//Custom Credential Handler for Self Service Links

CTXS.ExtensionAPI.addCustomCredentialHandler({

getCredentialTypeName: function () { return "nsg-custom-cred"; },
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
getCredentialTypeMarkup: function (requirements) {

return $("<div/>");

},

});
```

IMPORTANT:

When you are adding the HTML code, ensure that the return value starts with an HTML tag.

The XML portion indicates the logon page what to display, and the JavaScript code provides the actual text. The credential handler opens up the space and the label fills the space. Because all authentication traffic is now invisible to rewrite and responder, you can change the look and feel of the page. Configuration to customize login labels

1. Create and bind a theme based on RfWeb.

   ```
   add vpn portaltheme RfWebUI_MOD -basetheme RfWebUI

   bind vpn vserver TESTAAA –portaltheme RfWebUI_MOD
   ```

   The path for the files based on the theme is available in the directory; /var/netscaler/logon/themes/RfWebUI_MOD

2. Add the following snippet to the end of the script.js file:

   NOTE:

   Failing to include the preceding lines inside the correct file or missing to include any JavaScript functions prevent the XML from being loaded. The error can only be seen in the Developer Console of the browser with the following text: "Undefined Type `nsg-custom-cred`."

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
// Custom Label Handler for Self Service Links

CTXS.ExtensionAPI.addCustomAuthLabelHandler({

getLabelTypeName: function () { return "nsg-custom-label"; },

getLabelTypeMarkup: function (requirements) {

return $("<a href=\"https://identity.test.com/identity/faces/register\"
style=\"font-size: 16px;\" style=\"text-align: center;\">Self
Registration</a><br><a href=\"https://identity.test.com/identity/faces/
forgotpassword\" style=\"font-size: 16px;\" style=\"text-align: center;
\">Forgot Password</a><br><a href=\"https://identity.test.com/identity/
faces/forgotuserlogin\" style=\"font-size: 16px;\" style=\"text-align:
center;\">Forgot User Login</a>");

},

// Instruction to parse the label as if it was a standard type

parseAsType: function () {

return "plain";

}

});

//Custom Credential Handler for Self Service Links

CTXS.ExtensionAPI.addCustomCredentialHandler({

getCredentialTypeName: function () { return "nsg-custom-cred"; },

getCredentialTypeMarkup: function (requirements) {

return $("<div/>");

},

});
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT:

When you are adding the HTML code, ensure that the return value starts with an HTML tag.

Login schema used in this example

```
<?xml version="1.0" encoding="utf-8"?>

<AuthenticateResponse xmlns="http://citrix.com/authentication/response/1">

<Status>success</Status>

<Result>more-info</Result>

<StateContext/>

<ReadOnly>false</ReadOnly>
<InitialValue/>
<Constraint>.+</Constraint>
</Text>
</Input>
</Requirement>
<Requirement>
<Credential>
<Type>nsg-custom-cred</Type>
<ID>passwd</ID>
</Credential>
<Label>
<Type>nsg-custom-label</Type>
</Label>
</Requirement>
<Requirement>
<Credential>
<ID>loginBtn</ID>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Type>none</Type>

</Credential>

<Label>

<Type>none</Type>

</Label>

<Input>

<Button>Please Log On</Button>

</Input>

</Requirement>

</Requirements>

</AuthenticationRequirements>

</AuthenticateResponse>
```

Run the following commands to load the custom schema to config.

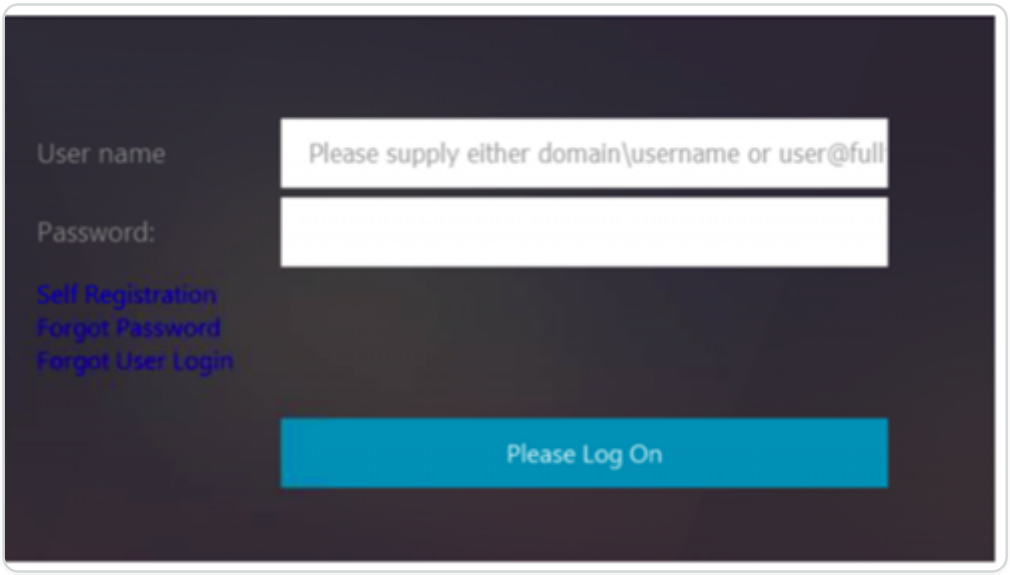
```
add authentication loginSchema custom -authenticationSchema custom.xml

add authentication loginSchemaPolicy custom -rule true -action custom

bind authentication vserver AAATEST -policy custom -priority 100
-gotoPriorityExpression END
```

The following figure displays the login page that is rendered with this configuration.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Customize UI to display images

nFactor allows for customized display with the use of login schema files. There might be a requirement for further customizations other than those offered by the built-in login schema files. For example, displaying a hyperlink or writing custom logic in the UI. These can be achieved using 'custom credentials' that comprises the login schema extension and corresponding javascript file.

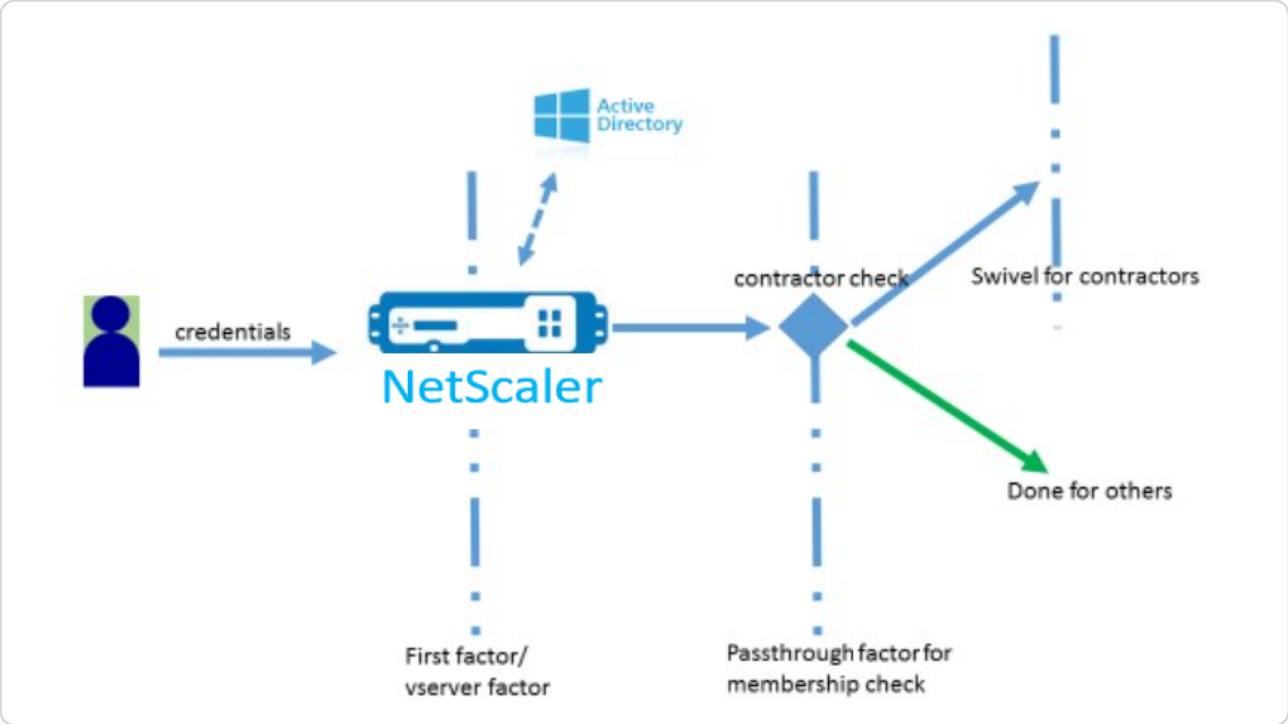
Login schema files can be found in the `/nsconfig/loginschema/LoginSchema` directory.

For UI customization to display images, a deployment flow in the "NetScaler-Swivel" integration is used as an example.

There are two factors in this flow.

- First factor: Checks user's AD credentials.
- Second factor: Prompts for user logon based on group membership.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



In this flow, all users go through the first factor. Before the second factor, there is a pseudo factor to check if some users can be omitted from the "swivel" factor. If the user requires the "swivel" factor, an image and a text box are displayed to enter the code.

Solution

The solution for customizing the UI to display images contains two parts;

- Login schema extension.
- Custom script to process the login schema extension.

Login schema extension

To control form rendering, a custom 'id'/'credential' is injected into the login schema. This can be done by reusing the existing schema and modifying as per the requirement.

In the example, a login schema that has only one text field (such as /nsconfig/loginschema/LoginSchema/OnlyPassword.xml) is considered. The following snippet is added to the login schema.

```
<Requirement><Credential><ID>swivel_cred</ID><Type>swivel_cred</
Type><Input><Text><Hidden>true</Hidden><InitialValue>${http.req.user.name}
</InitialValue></Text></Input></Credential></Requirement>
```

In the snippet, "swivel_cred" is specified as the "Type" of the credential. Because this is not recognized as a built-in 'credential,' UI looks for a handler for this type, and calls it if it exists. An

© 1997–2026 Citrix Systems, Inc. All rights reserved.

initial value is sent for this credential which is an expression that NetScaler dynamically fills. In the example, it is the user's name used to notify the swivel server of the user name. It might not be needed all the time or it can be augmented with some other data. Those details must be added as required.

Javascript to handle custom credential

When the UI finds a custom credential, it looks for a handler. All custom handlers are written in /var/netscaler/logon/LogonPoint/custom/script.js for the default portal theme.

For the custom portal themes, script.js can be found in the directory `/var/netscaler/logon/themes/<custom_theme>/`.

The following script is added to render markup for custom credentials.

```
CTXS.ExtensionAPI.addCustomCredentialHandler({

    // The name of the credential, must match the type returned by the
server

    getCredentialTypeName: function () { return "swivel_cred"; },

    // Generate HTML for the custom credential

    getCredentialTypeMarkup: function (requirements) {

        var div = $("<div></div>");

        var image = $("<img/>");

        var username = requirements.input.text.initialValue; //Get the
secret from the response

        image.attr({

            "style" : "width:200px;height:200px;",

            "id" : "qrcodeimg",

            "<Enter your server URL here>"

        });
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
        div.append(image);

        return div;

    }

});
```

This snippet is for handling the mark-up for 'swivel_cred'. Credential name highlighted must match the 'type' specified earlier in the login schema extension. To generate mark-up, an image whose source points to the swivel server needs to be added. Once this is done, UI loads the image from the specified location. Because this login schema also has a textbox, UI renders that text box.

NOTE:

Administrator can modify the "style" of the image element to resize the image. Currently it configured for 200x200 pixels.

Configuration for customizing UI to display images

nFactor configuration is better constructed bottom-up, that is the last factor first because when you try to specify 'nextFactor' for the previous factors, you require the subsequent factor's name.

Swivel factor configuration:

```
add loginschema swivel_image –authenticationSchema /nsconfig/loginschema/
SwivelImage.xml

add authentication policylabel SwivelFactor –loginSchema swivel_image

bind authentication policylabel SwivelFactor –policy <policy-to-check-
swivel-image> -priority 10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Download SwivelImage.xml from the login schema used in the example.

Pseudo factor for group check configuration:

```
add authentication policylabel GroupCheckFactor

add authentication policy contractors_auth_policy –rule
‘http.req.user.is_member_of(“contractors”)’ –action NO_AUTHN

add authentication policy not_contractors _auth_policy–rule true –action
NO_AUTHN

bind authentication policylabel GroupCheckFactor –policy
contractors_auth_policy –pri 10 –nextFactor SwivelFactor

bind authentication policylabel GroupCheckFactor –policy
not_contractors_auth_policy –pri 20
```

First factor for Active Directory login:

```
add ldapAction <>

add authentication policy user_login_auth_policy –rule true –action <>

bind authentication vserver <> -policy user_login_auth_policy –pri 10 –
nextFactor GroupCheckFactor
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In the configuration, three factors are specified of which one is implicit/pseudo.

Login schema used in this example

The following is an example schema with swivel credential and a text box.

NOTE:

When copying data for a web browser, quotes might be displayed differently. Copy data in editors like notepad before saving them to files.

```
<?xml version="1.0" encoding="UTF-8"?>

<AuthenticateResponse xmlns="http://citrix.com/authentication/response/1">

<Status>success</Status>

<Result>more-info</Result>

<StateContext></StateContext>

<AuthenticationRequirements>

<PostBack>/nf/auth/doAuthentication.do</PostBack>

<CancelPostBack>/nf/auth/doLogoff.do</CancelPostBack>

<CancelButtonText>Cancel</CancelButtonText>

<Requirements>

<Requirement><Credential><ID>swivel_cred</ID><Type>swivel_cred</
Type><Input><Text><Hidden>true</Hidden><InitialValue>${http.req.user.name}
</InitialValue></Text></Input></Credential></Requirement>

<Requirement><Credential><ID>passwd</ID><SaveID>ExplicitForms-Password</
SaveID><Type>password</Type></Credential><Label><Text>Password:</
Text><Type>plain</Type></Label><Input><Text><Secret>true</
Secret><ReadOnly>false</ReadOnly><InitialValue></
InitialValue><Constraint>.+</Constraint></Text></Input></Requirement>

<Requirement><Credential><Type>none</Type></Credential><Label><Text>Hello
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
${http.req.user.name}, Please enter passcode from above image.</
Text><Type>confirmation</Type></Label><Input /></Requirement>

<Requirement><Credential><ID>saveCredentials</ID><Type>savecredentials</
Type></Credential><Label><Text>Remember my password</Text><Type>plain</
Type></Label><Input><CheckBox><InitialValue>false</InitialValue></
CheckBox></Input></Requirement>

<Requirement><Credential><ID>loginBtn</ID><Type>none</Type></
Credential><Label><Type>none</Type></Label><Input><Button>Log On</
Button></Input></Requirement>

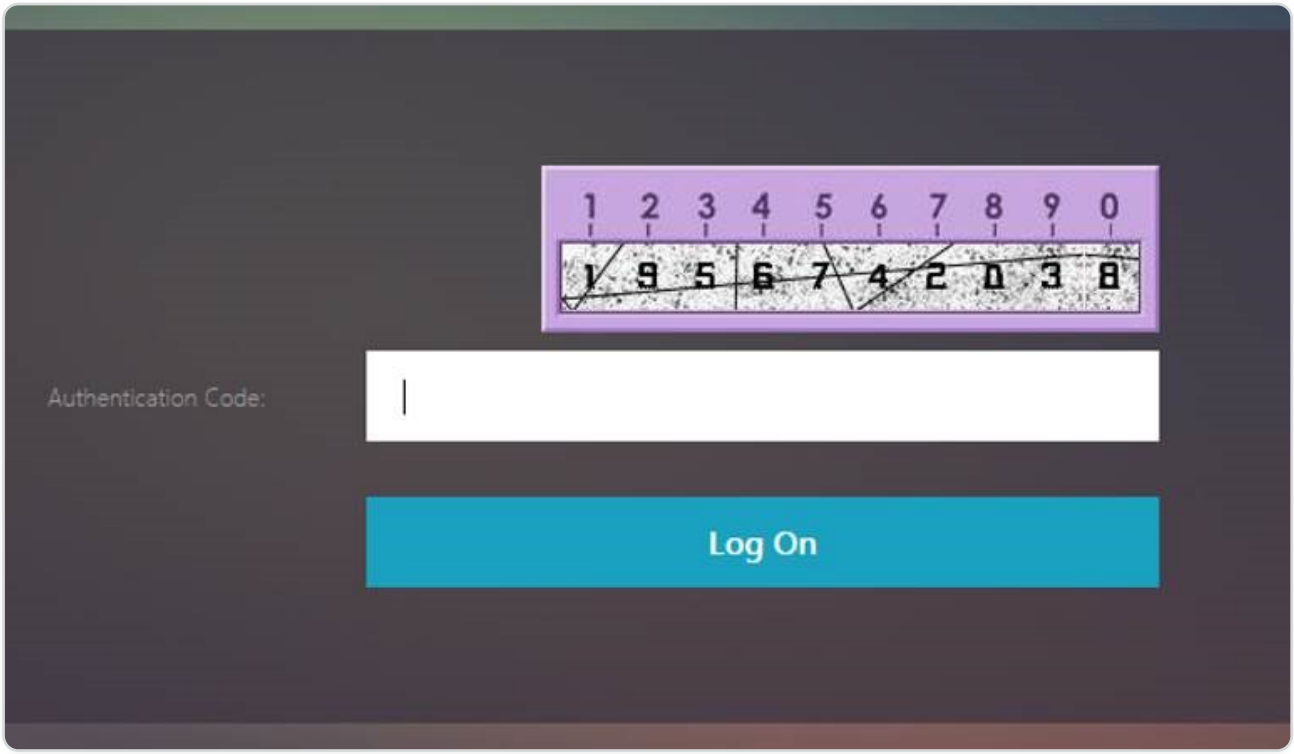
</Requirements>

</AuthenticationRequirements>

</AuthenticateResponse>
```

Output

Once the configuration is performed, the following image is displayed.



NOTE:

Image height and placement can be altered in the JavaScript.

Customize NetScaler nFactor logon form to show or hide fields

NetScaler Gateway's RfWeb UI allows for wide variety of customizations. This capability when combined with the nFactor authentication framework lets customers configure complex flows without compromising existing workflows.

In this example, two authentication options, OAuth and LDAP are available from the Logon Type list. When the form is first loaded, the user name and password fields (LDAP is shown first) are displayed. If OAuth is selected, all the fields are hidden because OAuth implies an offload of authentication to a third party server. This way, an administrator can configure intuitive workflows as per user convenience.

NOTE:

- The values in the Logon Type list can be modified with simple modifications to the script file.
- This section describes only the UI part of the flow. The run time handling of the authentication is outside the scope of this article. Users are recommended to refer to the nFactor documentation for authentication configuration.

How to customize nFactor logon form

Customizing nFactor logon form can be classified into two parts

- Sending the right login schema to the UI
- Writing a handler to interpret login schema and user selections

Send the correct login schema to the UI

In this example, a simple claim/requirement is sent in the login schema.

For this, the SingleAuth.xml file is modified. The SingleAuth.xml is shipped with NetScaler firmware and can be found in the `/nsconfig/loginschema/LoginSchema` directory.

Steps to send login schema:

1. Log in via SSH and drop to shell (type 'shell').
2. Copy SingleAuth.xml to a different file for modification.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

The destination folder is different from the default NetScaler login schemas folder.

cp /nsconfig/loginschema/LoginSchema/SingleAuth.xml /nsconfig/loginschema/SingleAuthDynamic.xml

3. Add the following claim to SingleAuthDynamic.xml.

```
<Requirement><Credential><ID>nsg_dropdown</ID><Type>nsg_dropdown</
Type></Credential><Label><Text>Logon Type:</Text><Type>plain</Type></
Label></Requirement>
```

4. Configure NetScaler to send this login schema to load the first form.

```
add loginschema single_auth_dynamic –authenticationSchema
SingleAuthDynamic.xml

add loginschemaPolicy single_auth_dynamic –rule true –action
single_auth_dynamic

bind authentication vserver aaa_nfactor –policy single_auth_dynamic –
pri 10
```

Script changes to load form and handle user events

You can modify the JavaScript that enables an administrator to customize the display for the logon form. In this example, the user name and password field are displayed if LDAP is chosen and are hidden if OAuth is chosen. Administrator can also hide only the password.

Admins must append the following snippet to "script.js" that is at "/var/netscaler/logon/LogonPoint/custom" directory.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

Because this directory is a global directory, create a portal theme and edit the "script.js" file within that folder, at `"/var/netscaler/logon/themes/<THEME_NAME>"`.

```
CTXS.ExtensionAPI.addCustomCredentialHandler({

    // The name of the credential, must match the type returned by the
server

    getCredentialTypeName: function () { return "nsg_dropdown"; },

    // Generate HTML for the custom credential

    getCredentialTypeMarkup: function (requirements) {

        var div = $("<div></div>");

        var select = $("<select name='nsg_dropdown'></select>").attr("id",
"nsg_dropdown");

        var rsa = $("<option></option>").attr("selected",
"selected").text("LDAP").val("LDAP");

        var OAuthID = $("<option></option>").text("OAuth").val("OAuth");

        select.append(rsa, OAuthID);

        select.change(function(e) {

            var value = $(this).val();

            var ldapPwd = $($
(".credentialform").find(".CredentialTypepassword")[0]);

            var ldapUname = $($
(".credentialform").find(".CredentialTypeusername"));
```

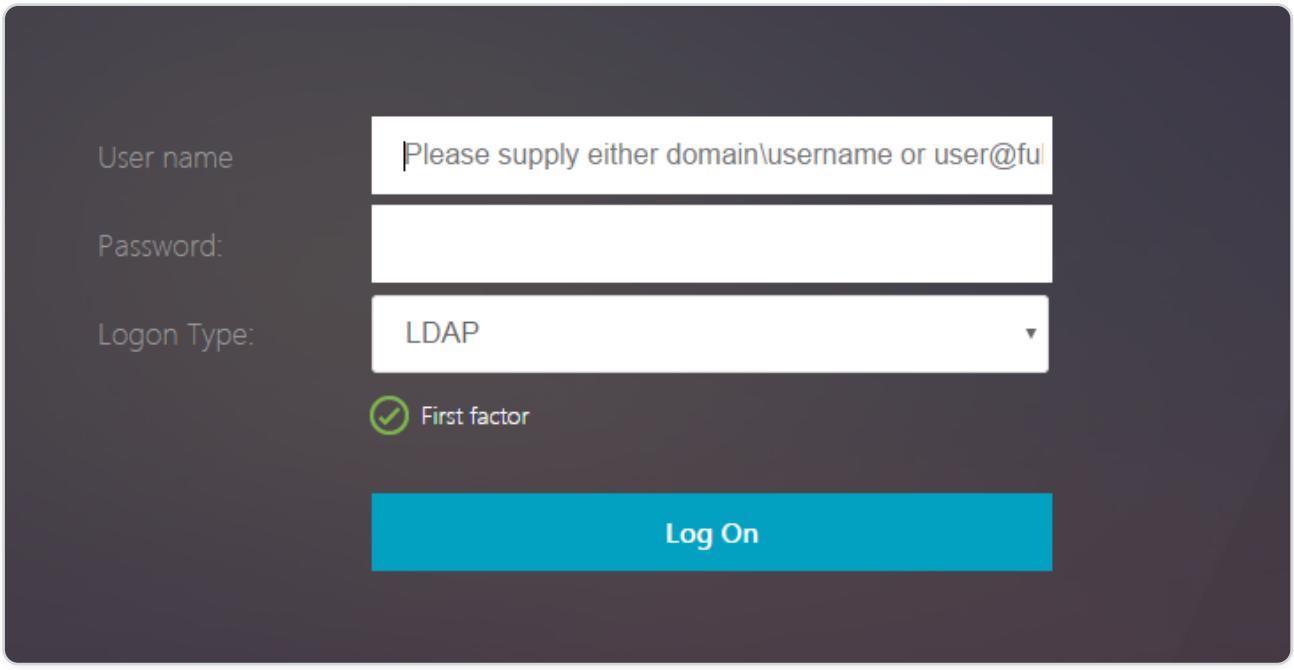
© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
            if(value == "OAuth") {
                if (ldapPwd.length)
                        ldapPwd.hide();
                if (ldapUname.length)
                        ldapUname.hide();
            } else if(value == "LDAP") {
                if (ldapPwd.length)
                        ldapPwd.show();
                if (ldapUname.length)
                        ldapUname.show();
            }
         });
        div.append(select);
         return div;
    }
});
```

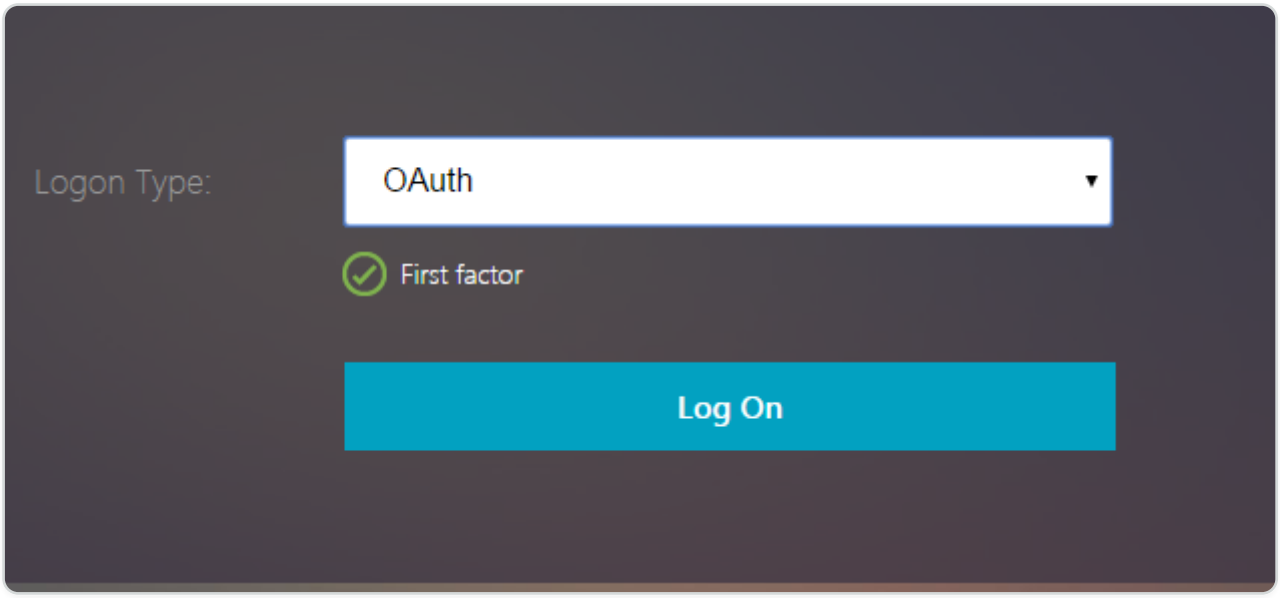
End-user experience

When an end user loads the logon page first time, the following screen appears.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



If **OAuth** is selected in **Logon Type**, user name and password fields are hidden.



If **LDAP** is selected, user name and password are displayed. This way, the logon page can be dynamically loaded based on user selection.

Login schema used in this example

```
<?xml version="1.0" encoding="UTF-8"?>

```
</AuthenticationRequirements>

</AuthenticateResponse>
```

NOTE:

For more details about various nFactor related topics, see nFactor authentication.

Set a cookie using nFactor

You can apply the nFactor custom labels and set a cookie as a factor of the authentication flow. Through custom labels, you can use JavaScript to manipulate the login schema.

To set a cookie as a factor, you do not need to display any information to the user, which is performed with a no schema login. Instead, you must interact with the user's browser to instruct the login schema to store the desired data. A login schema is required to set the cookie when the page is loaded. The cookie is set with a custom label and JavaScript code.

To implement a factor that sets a cookie, create an XML file called cookie.xml to store the schema in the /nsconfig/loginschema/ directory with the following content:

```
<?xml version="1.0" encoding="UTF-8"?>

<AuthenticateResponse xmlns="http://citrix.com/authentication/response/1">

<Status>success</Status>

<Result>more-info</Result>

<StateContext></StateContext>

<AuthenticationRequirements>

<PostBack>/nf/auth/doAuthentication.do</PostBack>

<CancelPostBack>/nf/auth/doLogoff.do</CancelPostBack>

<CancelButtonText>Cancel</CancelButtonText>

<Requirements>
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<Requirement>
<Credential><ID>nsg_cookie</ID><Type>nsg_cookie</Type></Credential>
<Label><Text>Logon Type:</Text><Type>Plain</Type></Label>
</Requirement>

<Requirement>
<Credential><ID>loginBtn</ID><Type>none</Type></Credential>
<Label><Type>none</Type></Label><Input><Button>Log On</Button></Input>
</Requirement>

</Requirements>
</AuthenticationRequirements>
</AuthenticateResponse>
```

In this XML;

- The custom label nsg_cookie is used to create the cookie and submit the form, and the form button.
- The RfWebUI_custom is the new Portal theme based on the RfWebUI theme.

Steps to set a cookie using nFactor

1. Create a portal theme based on the RfWebUI theme.

   ```
   add vpn portaltheme RfWebUI_custom -basetheme RfWebUI
   ```

   This command creates a folder for this theme at /var/netscaler/logon/themes/RfWebUI_custom
2. Edit the file /var/netscaler/logon/themes/RfWebUI_custom/script.js and add the following script:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
CTXS.ExtensionAPI.addCustomCredentialHandler({

    // The name of the credential, must match the type returned by the
server

    getCredentialTypeName: function () { return "nsg_cookie"; },

    // Generate HTML for the custom credential

    getCredentialTypeMarkup: function (requirements) {

        var div = $("<div></div>");

        $(document).ready(function() {

        //Set cookie valid for 1000 days

        var exdays = 1000;

        var d = new Date();

        d.setTime(d.getTime() + (exdays*24*60*60*1000));

        var expires = "expires="+ d.toUTCString();

        document.cookie = "NSC_COOKIE_NAME=CookieValue;" + expires +
";path=/";

        //Submit form

        document.getElementById('loginBtn').click();

        });

        return div;

    }

});
```

This code performs the following:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Waits for the browser to finish loading the page
- Sets a cookie called NSC_COOKIE_NAME with the value CookieValue, valid for 1000 days
- Auto-submits the form.

The cookie is created and the user does not need to interact with the page.

3. Create a login schema to bind to the policy label that represents the set cookie factor.

```
add authentication loginSchema Cookie_LS -authenticationSchema "/
nsconfig/loginschema/cookie.xml"
```

4. Create a NO_AUTHN authentication policy to bind to the policy label that represents the set cookie factor.

```
add authentication Policy NO_AUTHN_POL -rule TRUE -action NO_AUTHN
```

This policy always evaluates as true, moving the user to the next factor or completing the authentication flow.

5. Bind the portal theme RfWebUI_custom to the NetScaler Gateway virtual server or NetScaler AAA virtual server.

Sample deployments using nFactor authentication

The following are the sample deployments using nFactor authentication:

- Getting two passwords up-front, pass-through in next factor. Read
- Group extraction followed by certificate or LDAP authentication, based on group membership. Read
- SAML followed by LDAP or certificate authentication, based on attributes extracted during SAML. Read
- SAML in first factor, followed by group extraction, and then LDAP or certificate authentication, based on groups extracted. Read
- Prefilling user name from certificate. Read
- Certificate authentication followed by group extraction for 401 enabled traffic management virtual servers. Read
- Username and two passwords with group extraction in third factor. Read

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Certificate fallback to LDAP in same cascade; one virtual server for both certificate and LDAP authentication. Read
- LDAP in first factor and WebAuth in second factor. Read
- Domain drop down in first factor, then different policy evaluations based on group. Read
- Configure email ID (or user name) input based group extraction at first factor to decide the next factor authentication flow. Read

How to articles

The Authentication, authorization, and auditing "How to articles" are simple, relevant, and easy to implement articles. These articles contain information about some of the popular Authentication, authorization, and auditing features such LDAP authentication and multifactor authentication.

Endpoint Analysis

Configure pre-authentication Endpoint Analysis scan as a factor in nFactor authentication

Configure post-authentication Endpoint Analysis scan as a factor in NetScaler nFactor authentication

Configure pre-authentication and post-authentication EPA scan as a factor in nFactor authentication

Configure periodic Endpoint Analysis scan as a factor in nFactor authentication

Configure NetScaler Gateway preauthentication EPA scan for the domain check

First factor and second factor configuration combinations

Configure nFactor for NetScaler Gateway with WebAuth in first factor and LDAP with password change in second factor

Configure SAML followed by LDAP or certificate authentication based on SAML attribute extraction in nFactor authentication

Configure certificate authentication as first factor and LDAP as second factor in NetScaler nFactor authentication

Configure two-factor authentication with one login schema and one passthrough schema in NetScaler nFactor authentication

Configure user name and two passwords with group extraction in third factor by nFactor authentication

Protected user as an authentication factor

Configure protected user as an authentication factor in NetScaler nFactor authentication

SAML authentication

Security Assertion Markup Language (SAML) is an XML-based authentication mechanism that provides single sign-on capability and is defined by the OASIS Security Services Technical Committee.

Note

> Starting from NetScaler 12.0 Build 51.x, NetScaler appliance used as a SAML Service Provider (SP) with Multi-Factor (nFactor) authentication now prepopulates the user-name field on the login page. The appliance sends a NameID attribute as part of a SAML authorization request, retrieves the NameID attribute value from the NetScaler SAML Identity Provider (IdP), and prepopulates the user-name field.

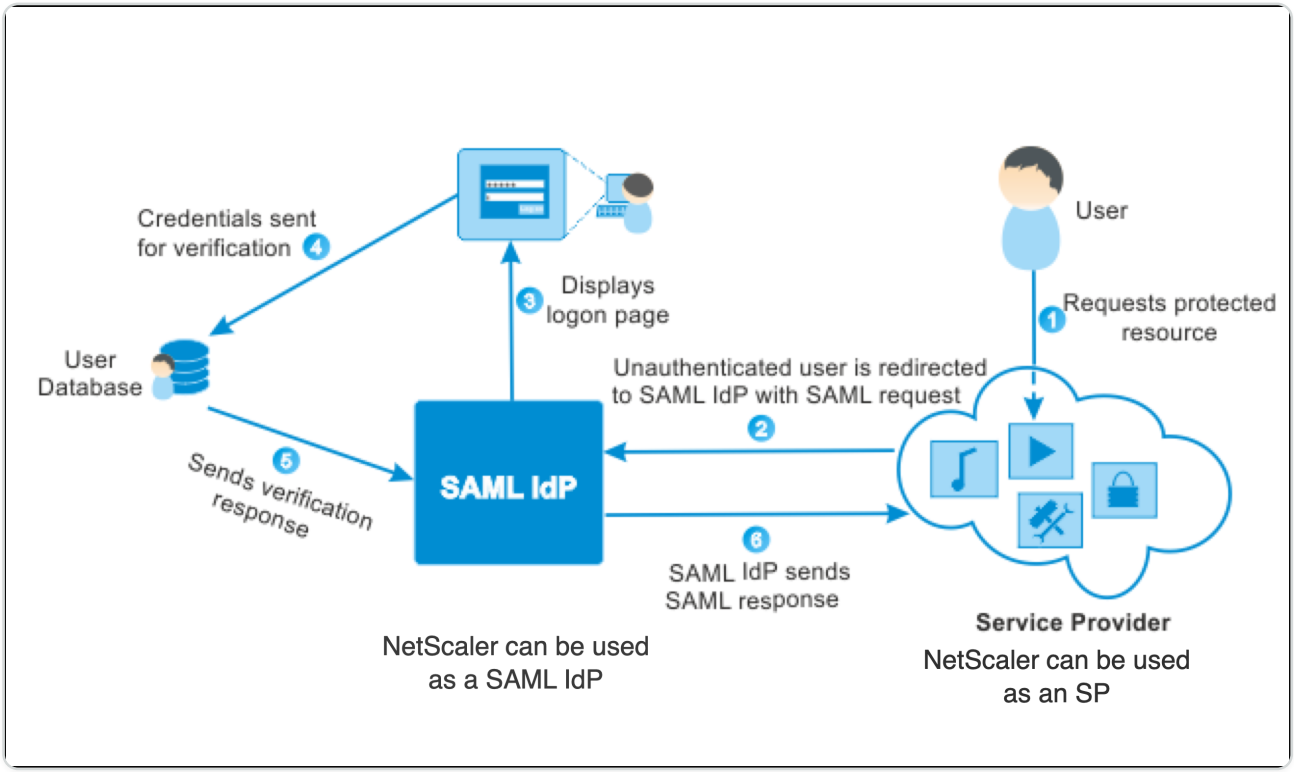
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Why use SAML authentication

Consider a scenario in which a service provider (LargeProvider) hosts a number of applications for a customer (BigCompany). BigCompany has users that must seamlessly access these applications. In a traditional setup, LargeProvider would need to maintain a database of users of BigCompany. This raises some concerns for each of the following stakeholders:

- LargeProvider must ensure security of user data.
- BigCompany must validate the users and keep the user data up-to-date, not just in its own database, but also in the user database maintained by LargeProvider. For example, a user removed from the BigCompany database must also be removed from the LargeProvider database.
- A user has to log on individually to each of the hosted applications.

The SAML authentication mechanism provides an alternative approach. The following deployment diagram shows how SAML works (SP initiated flow).



The concerns raised by traditional authentication mechanisms are resolved as follows:

- LargeProvider does not have to maintain a database for BigCompany users. Freed from identity management, LargeProvider can concentrate on providing better services.
- BigCompany does not bear the burden of making sure the LargeProvider user database is kept in sync with its own user database.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- A user can log on once, to one application hosted on LargeProvider, and be automatically logged on to the other applications that are hosted there.

The NetScaler appliance can be deployed as a SAML Service Provider (SP) and a SAML Identity Provider (IdP). Read through the relevant topics to understand the configurations that must be performed on the NetScaler appliance.

A NetScaler appliance configured as a SAML service provider can now enforce an audience restriction check. The audience restriction condition evaluates to “Valid” only if the SAML replying party is a member of at least one of the specified audiences.

You can configure a NetScaler appliance to parse attributes in SAML assertions as group attributes. Parsing them as group attributes enables the appliance to bind policies to the groups.

NetScaler as a SAML SP

The SAML service provider (SP) is a SAML entity deployed by the service provider. When a user tries to access a protected application, the SP evaluates the client request. If the client is unauthenticated (does not have a valid NSC_TMAA or NSC_TMAS cookie), the SP redirects the request to the SAML identity provider (IdP).

The SP also validates SAML assertions that are received from the IdP.

When the NetScaler appliance is configured as an SP, a traffic management virtual server (load balancing or content switching) receives all user requests associated with the relevant SAML action.

The NetScaler appliance also supports POST and Redirect bindings during logout.

NOTE

A NetScaler appliance can be used as a SAML SP in a deployment where the SAML IdP is configured either on the appliance or on any external SAML IdP.

When used as a SAML SP, a NetScaler appliance:

- Can extract the user information (attributes) from the SAML token. This information can then be used in the policies that are configured on the NetScaler appliance. For example, if you want to extract the GroupMember and **emailaddress** attributes in the SAMLAction, specify the **Attribute2** parameter as GroupMember and the **Attribute3** parameter as **emailaddress**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

Default attributes such as user name, password, and logout URL must not be extracted in attributes 1–16, because they as are implicitly parsed and stored in the session.

- Can extract attribute names of up to 127 bytes from an incoming SAML assertion. The previous limit was 63 bytes.
- Supports post, redirect, and artifact bindings.

NOTE

Do not use redirect binding for large amounts of data when the assertion after inflate or decoding is greater than 10K.

- Can decrypt assertions.

NOTE:

The supported decryption algorithms are DES3, AES128, AES192, AES256, and RSA-OAEP.

- Can extract multi-valued attributes from a SAML assertion. These attributes are sent is nested XML tags such as:

  \<AttributeValue\> \<AttributeValue\>Value1\</AttributeValue\>
  \<AttributeValue\>Value2\</AttributeValue\> \</AttributeValue\>

  NOTE

  From NetScaler 13.0 Build 63.x and above, the individual maximum length for SAML attributes has been increased to allow a maximum of 40k bytes. The size of all the attributes must not exceed 40k bytes.

  When presented with previous XML, the NetScaler appliance can extract both Value1 and Value2 as values of a given attribute, as opposed to the old firmware that extracts only Value1.

- Can specify the validity of a SAML assertion.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If the system time on NetScaler SAML IdP and the peer SAML SP is not in sync, the messages might get invalidated by either party. To avoid such cases, you can now configure the time duration for which the assertions are valid.

This duration called the "skew time," specifies the number of minutes for which the message can be accepted. The skew time can be configured on the SAML SP and the SAML IdP.

- Can send an extra attribute called 'ForceAuth' in the authentication request to an external IdP (identity provider). By default, the ForceAuthn is set to 'False'. It can be set to 'True' to suggest IdP to force authentication despite the existing authentication context. Also, NetScaler SP does authentication request in query parameter when configured with artifact binding.

Configure the NetScaler appliance as a SAML SP by using the CLI

1. Configure a SAML SP action.

   Example

   The following command adds a SAML action that redirects unauthenticated user requests.

   ```
   add authentication samlAction SamlSPAct1 -metadataUrl "https://ksidp1.ksaaa.local/metadata/samlidp/SAML_IDP_profile" -samlIdPCertName nssp -preferredbindtype SSOREDIRECT -samlSigningCertName nssp –samlRedirectUrl https://auth1.example.com -relaystateRule "AAA.LOGIN.RELAYSTATE.EQ(\"https://lb.example1.com/\")"
   ```

   Points to note

   - Certificate provided for `-samlIdPCertName` in the samlAction command must match the corresponding certificate from IdP for the signature verification to succeed.
   - SAML supports only the RSA certificate. Other certificates like HSM and FIPS are not supported.
   - It is recommended to have a full domain name with a trailing '/' in the expression.
   - If the authentication virtual server is configured as a SAML IdP, the metadata URL that must be used in the SAML SP action is `https://<netscaler-saml-idp-fqdn>/metadata/samlidp/SAML_IDP_profile`.
   - If multiple SAML policies are part of an IdP chain, it is sufficient to configure a relay state rule only on the first SAML policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For details on this command, see `<https://developer-docs.netscaler.com/en-us/adc-command-reference-int/current-release/authentication/authentication-samlaction>` and `<https://support.citrix.com/article/CTX316577>`.

2. Configure the SAML policy.

   Example:

   The following command defines a SAML policy that applies the previously defined SAML action to all traffic.

   ```
   add authentication policy SamlSPPol1 -rule true -action SamlSPAct1
   ```

3. Bind the SAML policy to the authentication virtual server.

   Example

   The following command binds the SAML policy to an authentication virtual server named "av_saml".

   ```
   bind authentication vserver av_saml -policy SamlSPPol1
   ```

4. Bind the authentication virtual server to the appropriate traffic management virtual server.

   Example

   The following command adds a load balancing virtual server named "lb1_ssl" and associates the authentication virtual server named "av_saml" to the load balancing virtual server. `add lb vserver lb1_ssl SSL 10.217.28.224 443 -persistenceType NONE -cltTimeout 180 -AuthenticationHost auth1.example.com -Authentication ON -authnVsName av_saml`

   For details on this command, see authentication-samlAction.

Configure a NetScaler appliance as a SAML SP by using the GUI

1. Configure a SAML SP action.

   a. Navigate to **Security** -> **AAA - Application Traffic** -> **Policies** -> **Authentication** -> **Basic Policies** -> **SAML**.

   b. On the **Servers** tab, click **Add**, enter values for the following parameters, and click **Create**.

      Parameter descriptions:

      - **Name:** Name of the server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Export SAML Metadata:** Click this link if you want to export the metadata of the SAML profile to a NetScaler Gateway VPN virtual server.
- **Import Metadata:** This option imports the SAML metadata. This option is enabled by default.
    - If the **Import Metadata** option is disabled, enter the values for the following parameters:
        - **Redirect URL:** URL that users authenticate against. Some IdPs have special URLs that are not reachable unless they are on a SAML setup.
        - **Single Logout URL:** URL specified so that the NetScaler can recognize when to send the client back to the IdP to complete the sign-out process.
        - **SAML Binding:** A mechanism that is used to transport SAML requestor and responder messages between the SP and IdP. When NetScaler acts as an SP, it supports Post, Redirect, and Artifact bindings. The default binding method is POST.

          NOTE:

          For Artifact binding, the transport mechanism on the SP and IdP must be the same.

        - **Logout Binding:** Specifies the transport mechanism of SAML logout messages. The default binding mechanism is Post.
        - **IDP Certificate Name:** IdPCert Certificate (Base64) present under SAML Signing Certificate.
- **SAML IDP Metadata URL:** Used to obtain the SAML metadata. You do not have to specify the IdP certificate name and the redirect URL fields when the metadata URL is present.

  When you configure the metadata URL, the SAML IdP sends the binding type options for SSO and Logout to NetScaler. By default, NetScaler selects Redirect as the binding type for Logout and Post as the binding type for SSO.

  The following is an example of the SAML IdP response that includes the options for binding type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<?xml version=\"1.0\"?> <md:EntityDescriptor
xmlns:md=\"urn:oasis:names:tc:SAML:2.0:metadata\"
ID=\"_b4743282f0a1e14164b8ccd429e8cee2\" entityID=\"192.0.2.255\">
<md:SingleLogoutService
Binding=\"urn:oasis:names:tc:SAML:2.0:bindings:HTTP -Redirect\"
Location=\"https://192.0.2.255 /cgi/tmlogout_redirect1\"></
md:SingleLogoutService> <md:SingleLogoutService
Binding=\"urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST\"
Location=\"https://192.0.2.255 /cgi/tmlogout_post1\"></
md:SingleLogoutService> <md:SingleSignOnServ ice
Binding=\"urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST\"
Location=\"https://192.0.2.255 /saml/login_post1\"> </
md:SingleSignOnService> <md:SingleSignOnService
Binding=\"urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect\"
Location=\"https://192.0.2.255 /saml/login_redirect1\"> </
md:SingleSignOnService> </md:EntityDescriptor>
```

You can modify the default binding types for SSO and Logout by configuring the **Preferred bind type** parameter.

NOTE:

Starting from release 14.1 build 29.x onwards, NetScaler configured as a SAML SP can retrieve and store multiple certificates from the same IdP using the SAML IdP metadata URL. This functionality allows the SP to select the correct certificate and validate SAML assertions from the IdP by using that certificate. The SP can store up to 4 certificates. This enhances the flexibility and robustness of the system.

- **Preferred Bind Type:** Specifies the preferred binding type for SSO and logout. This option is available from release 14.1 build 25.x onwards.

  In the previous SAML IdP response, for SSO, NetScaler selects Post as the SAML binding and chooses `https://192.0.2.255/saml/login_post1`, by default. You can modify this behavior by selecting the `SSOREDIRECT` checkbox as the preferred binding type.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

In the previous SAML IdP response, for Logout, NetScaler selects Redirect as the Logout binding type and chooses `https://192.0.2.255/cgi/tmlogout_redirect1`, by default. You can modify this behavior by selecting the `LOGOUTPOST` checkbox as the preferred binding type.

You can configure either one or both the binding types based on your preference.

- **Metadata Refresh Interval (mins):** Interval in minutes for fetching metadata from the specified metadata URL.
- **User Field:** Section of the IdP's SAML authentication form that contains the user name for SP to extract if necessary.
- **Signing Certificate Name:** Select the SAML SP certificate (with private key) that NetScaler uses to sign authentication requests to the IdP. The same certificate (without private key) must be imported to the IdP, so that the IdP can verify the authentication request signature. Most IdPs do not require the signing certificate name.
- **Issuer Name:** A unique ID that is specified on both the SP and IdP to help identify the service provider to each other.
- **Reject Unsigned Assertion:** Option that you can specify if you require the assertions from the IdP to be signed. The default option is **ON**.
  - **ON:** Rejects assertions without a signature
  - **STRICT:** Ensures that both response and assertion are signed
- **Audience:** Audience for which an assertion sent by IdP is applicable. This is typically an entity name or a URL that represents the service provider.
- **Signature Algorithm:** Algorithm to be used to sign/verify SAML transactions. The default value is RSA-SHA256.
- **Digest Method:** Algorithm to be used to compute/verify digest for SAML transactions. The default value is SHA256.
- **Relay State Rule:** Refer to Points to note about the `relaystateRule` parameter for details about this parameter.
- **State Check Rule:** Configure the expressions that are evaluated to validate HTTP requests on SAML endpoints.
- **Default Authentication Group:** The default group that is chosen when the authentication succeeds in addition to the extracted groups.
- **Group Name Field:** Name of the tag in an assertion that contains user groups.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Skew Time (mins):** This option specifies the clock skew in minutes that the NetScaler service provider allows on an incoming assertion. For example, if you set the skew time to 10 minutes at 16:00, the SAML assertion is valid from 15:50 to 16:10 - 20 minutes in total. The default skew time is 5 minutes.
- **Two Factor:** Enables the second factor authentication after SAML.
- **Assertion Consumer Service Index:** Index/ID of the metadata entry corresponding to this configuration.
- **Attribute Consuming Service Index:** Index/ID of the attribute specification at the IdP. The IdP locates the attributes requested by SP using this index and send those attributes in the SAML assertion.
- **Requested Authentication Context:** Specifies the context requirements of the authentication statements returned in the response.
- **Authentication Class Types:** Specifies the authentication class types that are requested from the IdP.
- **Custom Authentication Class Types:** Specifies the custom authentication class reference to be sent as part of the authentication request sent by the SP to SAML IdP.
- **Send Thumbprint:** Sends the thumbprint instead of the certificate in the SAML request.
- **Enforce Username:** Choose if the user name extracted from the SAML assertion can be edited on the login page while doing a second factor authentication.
- **Force Authentication:** Enforces authentication at the IdP that receives the request from NetScaler.
- **Store SAML Response:** Stores the entire SAML response as long as the user session is active.

2. Create a corresponding SAML policy.

   a. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy** and click **Add**.

   b. On the **Create Authentication Policy** page, provide the following details:

      - **Name:** Specify a name for the SAML policy.
      - **Action Type:** Select **SAML** as the authentication action type.
      - **Action:** Select the SAML server profile to bind the SAML policy with.
      - **Expression:** Displays the name of the rule or expression that the SAML policy uses to determine if the user must authenticate with the SAML server. On the text box, set the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

value "rule = true" for the SAML policy to take effect and the corresponding SAML action to be run.

3. Bind the SAML policy to the authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and associate the SAML policy with the authentication virtual server.

4. Associate the authentication server with the appropriate traffic management virtual server.

   Navigate to **Traffic Management > Load Balancing** (or **Content Switching**) > **Virtual Servers**, select the virtual server, and associate the authentication virtual server with it.

Points to note about the relaystateRule parameter

IMPORTANT:

To prevent phishing attacks, we recommend you to configure `relaysStateRule` parameter in the `samlAction`. For more information, see the NetScaler secure deployment guide.

Configure an expression for the `relaysStateRule` parameter in the `samlAction` command for a smooth authentication redirection after the SAML assertion. The expression must include a single published domain or a list of published domains that users want to connect to, before an authentication redirection. For example, the expression must contain the domains of the front-end virtual server (VPN, load balancing, or content switching) that uses the SAML action for authentication.

We recommend using full domain names with a trailing (`/`). For example `https://example.com/` .

The following examples describe the `relaystateRule` parameter configuration examples for single domain and multiple domain scenarios:

For a single domain:

```
set samlAction <samlActionName> -relaystateRule "AAA.LOGIN.RELAYSTATE.EQ(\"https://example1.com/\")"
```

For multiple domains:

Use pattern sets to add multiple domains:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add patset test1

bind patset test1 "https://example1.com/"

bind patset test1 "https://test1.com/"

bind patset test1 "https://10.11.11.112/"

set samlAction <samlActionName> -relaystateRule
AAA.LOGIN.RELAYSTATE.CONTAINS_ANY("test1")
```

To configure RegEx pattern matching for the FQDN:

```
set samlaction <samlActionName> -relaystateRule
"AAA.LOGIN.RELAYSTATE.REGEX_MATCH(re#^https://[a-zA-Z0-9]*\.example1\.com/
#)"
```

Specify the “\^” sign (`\^https`) at the starting of the domain and specify the forward slash “/” at the end of the expression (example: `example1\.com/`).

Following are some of definitions of the `relaystateRule` expressions:

```
EQ: Exact match.

CONTAINS: Domain inclusion.

CONTAINS_ANY: Match any domain from a PATSET.

REGEX_MATCH: Regex-based matching.
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Relay state rule configurations for different uses cases

The `relaystateRule` parameter in the `add authentication samlAction` command must be a PI expression. This expression is evaluated during the processing of the SAML response.

Administrators can configure the `relaystateRule` with necessary expressions based on their specific requirements. We recommend combining the custom expression with a recommended expression as per the use case.

AAATM use case

When the traffic management virtual server (load balancing or content switching) is enabled with authentication and the authentication virtual server acts as SAML SP, use the following expression:

```
AAA.LOGIN.RELAYSTATE.STARTSWITH("CS/LB vserver FQDN")
```

Example:

```
AAA.LOGIN.RELAYSTATE.STARTSWITH("https://lb.company.com/")
```

Sample configuration:

```
# The following configuration is an example and might not be complete for
direct use

add lb vserver lb.company.com SSL 22.116.181.171 443 -AuthenticationHost
samlsp.company.com -Authentication ON

...

add authentication vserver samlsp.company.com SSL 22.116.181.172 443

...

add authentication samlAction saml_sp_act -samlIdPCertName server_certkey
-samlSigningCertName server_certkey -samlRedirectUrl "https://
samlidp.company.com/saml/login" -samlUserField nameid -samlIssuerName
"https://samlspissuer.company.com" -relaystateRule
"AAA.LOGIN.RELAYSTATE.STARTSWITH(\"https://lb.company.com/\")"

add authentication Policy saml_sp_pol -rule true -action saml_sp_act
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
...

bind authentication vserver samlsp.company.com -policy saml_sp_pol
-priority 10 -gotoPriorityExpression NEXT
```

The preceding expression can be improved using a patset when multiple traffic management virtual servers (load balancing or content switching) share an authentication virtual server as a SAML SP.

```
# The following configuration is an example and might not be complete for
direct use

add lb vserver lb.company.com SSL 22.116.181.171 443 -AuthenticationHost
samlsp.company.com -Authentication ON

add lb vserver prodlb.company.com SSL 22.116.181.161 443
-AuthenticationHost samlsp.company.com -Authentication ON

add lb vserver stagelb.company.com SSL 22.116.181.151 443
-AuthenticationHost samlsp.company.com -Authentication ON

add patset test1

bind patset test1 "https://lb.company.com/"

bind patset test1 "https://prodlb.company.com/"

bind patset test1 "https://stagelb.company.com/"

...

add authentication vserver samlsp.company.com SSL 22.116.181.172 443

...

add authentication samlAction saml_sp_act -samlIdPCertName server_certkey
-samlSigningCertName server_certkey -samlRedirectUrl "https://
samlidp.company.com/saml/login" -samlUserField nameid -samlIssuerName
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"https://samlspissuer.company.com" -relaystateRule
"AAA.LOGIN.RELAYSTATE.CONTAINS_ANY("test1")"

add authentication Policy saml_sp_pol -rule true -action saml_sp_act

...

bind authentication vserver samlsp.company.com -policy saml_sp_pol
-priority 10 -gotoPriorityExpression NEXT
```

VPN use case

When authentication is enabled on a VPN virtual server using `authnProfile` and the authentication virtual server is bound to a SAML SP policy, use the following expression:

```
AAA.LOGIN.RELAYSTATE.STARTSWITH("VPN vserver FQDN")
```

Example:

```
AAA.LOGIN.RELAYSTATE.STARTSWITH("https://vpn.company.com/")
```

Sample configuration:

```
# The following configuration is an example and might not be complete for
direct use

add authentication vserver samlsp.company.com SSL 22.116.181.172 443

add authentication authnProfile authn_prof -authnVsName samlsp.company.com

add vpn vserver vpn.company.com SSL 22.116.181.141 443 -authnProfile
authn_prof

add authentication samlAction saml_sp_act -samlIdPCertName server_certkey
-samlSigningCertName server_certkey -samlRedirectUrl "https://
samlidp.company.com/saml/login" -samlUserField nameid -samlIssuerName
"https://samlspissuer.company.com" -relaystateRule
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
"AAA.LOGIN.RELAYSTATE.STARTSWITH(\"https://vpn.company.com/\")"

add authentication Policy saml_sp_pol -rule true -action saml_sp_act

bind authentication vserver samlsp.company.com -policy saml_sp_pol
-priority 10 -gotoPriorityExpression NEXT
```

IdP use case

When the authentication virtual server is configured as SAML IdP and also bound to SAML SP policy (for IdP chaining), use the following expression:

```
AAA.LOGIN.RELAYSTATE.LENGTH.EQ(0)
```

Sample configuration:

```
# The following configuration is an example and might not be complete for
direct use

add authentication vserver samlidp1.company.com SSL 22.116.181.172 443

# SAML IDP policy bound to authentication vserver and SAML IDP action not
in the scope of the explanation

add authentication samlIdPPolicy saml_idp_pol -rule true -action
saml_idp_prof

add authentication samlAction saml_sp_act -samlIdPCertName server_certkey
-samlSigningCertName server_certkey -samlRedirectUrl "https://
samlidp2.company.com/saml/login" -samlUserField nameid -samlIssuerName
"https://samlspissuer.company.com" -relaystateRule
"AAA.LOGIN.RELAYSTATE.LENGTH.EQ(0)"

add authentication Policy saml_sp_pol -rule true -action saml_sp_act

bind authentication vserver samlidp1.company.com -policy saml_idp_pol
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-priority 10 -gotoPriorityExpression NEXT

bind authentication vserver samlidp1.company.com -policy saml_sp_pol
-priority 10 -gotoPriorityExpression NEXT
```

NetScaler as a SAML IdP

The SAML IdP (Identity Provider) is a SAML entity that is deployed on the customer network. The IdP receives requests from the SAML SP and redirects users to a logon page, where they must enter their credentials. The IdP authenticates these credentials with the Active Directory (external authentication server, such as LDAP) and then generates a SAML assertion that is sent to the SP.

The SP validates the token, and the user is then granted access to the requested protected application.

When NetScaler is configured as an IdP, all requests are received by an authentication virtual server that is associated with the relevant SAML IdP profile.

NOTE

- NetScaler can be used as a IdP in a deployment where the SAML SP is configured either on the appliance or on any external SAML SP.
- NetScaler, when acting as an OpenID Provider, issues a bearer token for client credential requests and provides user information in JSON format through the introspection endpoint. Currently, the JWT (JSON Web Token) format is not supported in NetScaler.

When used as a SAML IdP, NetScaler:

- Supports all authentication methods that it supports for traditional logons.
- Digitally signs assertions.
- Supports single-factor and two-factor authentication. SAML must not be configured as the secondary authentication mechanism.
- Can encrypt assertions by using the public key of the SAML SP. This is recommended when the assertion includes sensitive information.
- Can be configured to accept only digitally signed requests from the SAML SP.
- Can log on to the SAML IdP by using the following 401-based authentication mechanisms: Negotiate, NTLM, and Certificate.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Can be configured to send 16 attributes in addition to the NameId attribute. The attributes must be extracted from the appropriate authentication server. For each of them, you can specify the name, the expression, the format, and a friendly name in the SAML IdP profile.
- If NetScaler is configured as a SAML IdP for multiple SAML SP, a user can gain access to applications on the different SPs without explicitly authenticating every time. NetScaler creates a session cookie for the first authentication, and every subsequent request uses this cookie for authentication.
- Can send multi-valued attributes in a SAML assertion.
- Supports post and redirect bindings. Support for artifact binding is introduced in NetScaler release 13.0 Build 36.27.
- Can specify the validity of a SAML assertion.

  If the system time on NetScaler SAML IdP and the peer SAML SP is not in sync, the messages might get invalidated by either party. To avoid such cases, you can now configure the time duration for which the assertions are valid.

  This duration called the "skew time," specifies the number of minutes for which the message must be accepted. The skew time can be configured on the SAML SP and the SAML IdP.
- Can be configured to serve assertions only to SAML SPs that are pre-configured on or trusted by the IdP. For this configuration, the SAML IdP must have the service provider ID (or issuer name) of the relevant SAML SPs.

  NOTE

  - Before you proceed, make sure that you have an authentication policy that is bound to an LDAP authentication virtual server.
  - For details on how to configure an LDAP action to retrieve the required attributes, see Name-value attribute support for LDAP authentication.

Configure NetScaler as a SAML IdP by using the CLI

1. Create a SAML IdP profile.

   Example

   Adding NetScaler as an IdP with SiteMinder as the SP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication samlIdPProfile SAML_IDP_profile -samlSPCertName
siteminder-cert -encryptAssertion ON -metadataUrl https://samlidp.example.com/
metadata -samlIdPCertName ns-cert -assertionConsumerServiceURL https://
example.com/cgi/samlauth -rejectUnsignedRequests ON -signatureAlg RSA-SHA256
-digestMethod SHA256 –acsUrlRule
AAA.LOGIN.SAML_REQ_ACS_URL.REGEX_MATCH(re#\^https://example.com/cgi/
samlauth$#)
```

2. Configure the SAML IdP profile. In the following example, the IdP session contains the "userPrincipalName" attribute.

   ```
   set samlidPProfile SAML_IDP_profile -Attribute1 "userPrincipalName"
   -Attribute1Expr "AAA.USER.ATTRIBUTE(\"userPrincipalName\")"
   ```

   Points to note

   - In the SAML IdP profile, configure **acsURLRule** that takes an expression of the list of applicable service provider URLs for this IdP. This expression depends on the SP being used. If NetScaler is configured as SP, the ACS URL is `https://<SP-domain_name>/cgi/samlauth`. It is recommended that you have a full URL in the expression for matching.
   - If you want the SAML IdP to allow only one ACS URL, use the following command:

     The following CLI example uses `https://testlb.aaa.local` as the ACS URL:

     ```
     set samlidpprofile SAML_IDP_profile -acsurlrule
      "AAA.LOGIN.SAML_REQ_ACS_URL.eq(\"https://testlb.aaa.local\")"
     ```

   - If you want the SAML IdP to match the ACS URL with a regular expression, use the following expression:

     ```
     –acsUrlRule AAA.LOGIN.SAML_REQ_ACS_URL.REGEX_MATCH(re#\^https://
     example.com/cgi/samlauth$#)
     ```

     The preceding expression ensures that the ACS URL matches with `https://example.com/cgi/samlauth`. The "\^" sign at the beginning of the regular expression ensures that NetScaler does not allow anything before "https". The "$" sign at the end of the regular expression ensures that NetScaler does not allow anything after "samlauth".

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If the expression is `-acsUrlRule AAA.LOGIN.SAML_REQ_ACS_URL.REGEX_MATCH(re#https://example.com/cgi/#)`, the SAML IdP allows any ACS URL as shown in the following examples:

  - `https://example.com/cgi/samlauth`
  - `abcdhttps://example.com/cgi/xyz`
  - `https://example.com/cgi/abcde`

- Some third-party SPs do not specify or send the ACS URL in SAML authentication requests. In such cases, use the following expression in the SAML IdP profile:

  `AAA.LOGIN.SAML_REQ_ACS_URL.LENGTH.EQ(0) || AAA.LOGIN.SAML_REQ_ACS_URL.EQ("https://fqdn/endpoint")`

- SAML supports only RSA certificate. Other certificates like HSM, FIPS are not supported.

  For more details on the command, see `<https://developer-docs.netscaler.com/en-us/adc-command-reference-int/current-release/authentication/authentication-samlaction>` and `<https://support.citrix.com/article/CTX316577>`.

- If the IdP logout URL is different from the redirect URL and the user is on the NetScaler login page for more than 2 minutes, a server error `HTTP/1.1 Internal Server Error 43549` appears when the user attempts to authenticate. The NetScaler logs display a message indicating that the incoming post logout redirect URL is not in the allowlisted logout redirect URLs for the user.

  To resolve this issue, bind the pattern set as shown in the following example:

  `bind patset ns_aaa_oauthidp_logout_redirect_uris "https://FQDN and path to the logout url"`

- If the authentication virtual server is configured as a SAML SP, the metadata URL that must be used in the SAML IdP profile is `https://<netscaler-saml-sp-fqdn>/metadata/samlsp/saml_sp_act`. For example,

  ```
  add authentication samlIdPProfile SAML_IDP_profile -samlIdPCertName
  aaa_local -assertionConsumerServiceURL "https://ksav.ksaaa.local/cgi/
  samlauth" -samlIssuerName "https://ksidp1.aaa.local/saml/login"
  -rejectUnsignedRequests OFF -serviceProviderID kslb.ksaaa.local
  -signAssertion NONE -SPLogoutUrl "https://ksav.ksaaa.local/cgi/tmlogout"
  -logoutBinding REDIRECT -metadataUrl "https://ksav.ksaaa.local/metadata/
  samlsp/saml_sp_act" -metadataRefreshInterval 1
  ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- By default, group attributes are sent in the following format in the SAML response when NetScaler acts as a SAML IdP:

```
<saml:AttributeValue>grp2</saml:AttributeValue>

<saml:AttributeValue>grp1</saml:AttributeValue>
```

You can customize the format of group attributes sent in SAML responses using the following two methods:

- Enabling comma-separated values
- Modifying XML tags

Enabling comma-separated values:

If you want all group attributes to be sent in a single `<saml:AttributeValue>` tag, separated by commas (for example, grp2, grp1), enable a specific `nsapimgr` knob using the following command.

```
nsapimgr_wr.sh -ys call=ns_saml_enable_comma_sep_attr_res
```

The `nsapimgr` knob is disabled by default.

Resulting group attribute format: `<saml:AttributeValue>grp2,grp1</saml:AttributeValue>`

To disable the `nsapimgr` knob, run the following command:

```
nsapimgr_wr.sh -ys call=ns_saml_disable_comma_sep_attr_res
```

Modifying XML tags:

If you want to change the XML tag used for group attributes (for example, from `<saml:AttributeValue>` to `<saml:AttrValue>`), use the `AAA.USER.GROUPS_AS_XML` expression. The `AAA.USER.GROUPS_AS_XML` expression allows you to specify a custom XML tag (for example, `saml:AttrValue`) for the group attributes in the SAML response.

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set samlidpprofile SAML_IDP_profile -attribute1 groups
-attribute1Expr AAA.USER.GROUPS_AS_XML("saml:AttrValue")
```

Resulting group attribute format:

```
<saml:AttrValue>grp2</saml:AttrValue>

<saml:AttrValue>grp1</saml:AttrValue>
```

3. Configure the SAML authentication policy and associate the SAML IdP profile as the action of the policy.

   `add authentication samlIdPPolicy samlIDPPol1 -rule true -action samlIDPProf1`

   NOTE:

   If the policy name includes one or more spaces, enclose the name in double or single quotation marks (for example, "my policy" or 'my policy').

4. Bind the policy to the authentication virtual server.

   `bind authentication vserver saml-auth-vserver -policy samlIDPPol1 -priority 100`

   For more details on the command, see `<https://developer-docs.netscaler.com/en-us/adc-command-reference-int/current-release/authentication/authentication-samlidpprofile>`.

Configure NetScaler as a SAML IdP by using the GUI

1. Configure a SAML IdP profile. This profile is used to verify the incoming authentication requests from the SP, and create and sign the assertion before sending it to the SP.

   a. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > SAML IDP**.

   b. On the **Profiles** tab, click **Add**, enter the values for the following parameters, and click **Create**.

   Parameter descriptions:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Name:** The name of the new SAML single sign-on profile.
- **Export SAML IDP Metadata:** Click this link if you want to export the metadata of the SAML IdP profile to a NetScaler Gateway VPN virtual server.
- **Import Metadata:** This option imports the SAML IdP metadata. This option is enabled by default.
    - If the **Import Metadata** option is disabled, enter the values for the following parameters:
        - **Assertion Consumer Service Url:** The URL to which the assertion must be sent.
        - **Service Provider Logout URL:** The SP endpoint to which logout messages must be sent.
        - **SAML Binding:** A mechanism that is used to transport SAML requestor and responder messages between the SP and IdP. When NetScaler acts as an SP, it supports **POST**, **REDIRECT**, and **ARTIFACT** bindings. The default binding method is **POST**. Associate the SAML IdP policy with an authentication virtual server. For **ARTIFACT** binding, the transport mechanism on the SP and IdP must be the same.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- For NetScaler SAML artifact binding, the Artifact Resolution Service URL value must be in the following format:

  `https://<your-idp-hostname>/saml/idp/artifactresolve`

- NetScaler sends the response assertion to the Assertion Consumer Service (ACS) URL specified in the incoming SAML `AuthnRequest` or the `SAMLIDPProfile`, depending on the SAML binding.
  - **POST binding:** For POST-bound requests, the `AssertionConsumerServiceURL` from the incoming SAML `AuthnRequest` takes precedence. If this URL is not present in the `AuthnRequest`, the system defaults to the `AssertionConsumerServiceURL` configured in the `SAMLIDPProfile`.
  - **REDIRECT binding:** For REDIRECT-bound requests, the `AssertionConsumerServiceURL` as defined in the `SAMLIDPProfile` configuration is always used.

- **Logout Binding:** Specifies the transport mechanism of the SAML logout messages. Available options are **POST** and **REDIRECT**.
- **SP Certificate Name:** Name of the SSL certificate of SAML relying party. This certificate is used to verify signature of the incoming AuthnRequest from a relying party or service provider. Maximum Length = 63.

- **SAML SP Metadata URL:** The URL that is used to obtain the SAML IdP metadata.

NOTE:

When the SAML SP metadata URL is configured, the following parameters are taken from the SAML IdP profile and are auto-filled in the SAML SP configuration:

- Assertion Consumer Service URL
- Service Provider Logout URL
- SP Certificate Name

© 1997–2026 Citrix Systems, Inc. All rights reserved.

    - Logout Binding
    - SAML Binding
    - Sign Assertion

- **Metadata Refresh Interval (mins):** The time interval (in minutes) for fetching the metadata from the specified metadata URL. The default time interval is 3600 minutes.
- **Assertion Consumer Service Url Rule:** Expression that is evaluated to allow Assertion Consumer Service URI coming in the SAML Request. Maximum Length = 8191.
- **IDP Certificate Name:** Name of the certificate used to sign the SAML response that is sent to the relying party or service provider after successful authentication. Maximum Length = 63.
- **Issuer Name:** The name to be used in requests sent from NetScaler Gateway to IdP to uniquely identify NetScaler Gateway. Maximum Length = 511.
- **Service Provider ID:** Unique identifier of the service provider that sends SAML request. NetScaler Gateway ensures that the issuer of the SAML request matches this URI. If there is an SP initiated sign-in scenario, this value must be same as `samlIssuerName` configured in `samlAction`. Maximum Length = 511.
- **Default Authentication Group:** The default group that is chosen when an authentication succeeds, in addition to the extracted groups. This group is useful for admins using the nFactor flow to decide the appropriate configurations for the relaying party. For example, when you configure an authentication policy, you can specify the default group name as part of the following expression:

  ```
  AAA.USER.IS_MEMBER_OF("Default Authentication Group name").
  ```

- **Audience:** The audience to whom the assertion is sent by the IdP. This parameter is usually an entity name or a URL that represents the SP.
- **Skew Time (mins):** This option specifies the number of minutes on either side of the current time that the assertion is valid. For example, if skewTime is 10, then assertion is valid from (current time - 10) min to (current time + 10) min, that is, 20 min in all. Default = 5.
- **Sign Assertion:** Option to sign portions of an assertion when NetScaler Gateway IdP sends one. Based on the user selection, either **ASSERTION** or **RESPONSE** or **BOTH** or **NONE** can be signed.
- **NAME ID format:** Format of name identifier sent in the assertion.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Name ID Expression:** Expression that is evaluated to obtain the NameIdentifier to be sent in the assertion.
- **Reject Unsigned Requests:** Option to reject unsigned SAML requests. When enabled, NetScaler Gateway denies any authentication requests that arrive without signature.
- **Signature Algorithm:** Algorithm used to sign and verify the assertions between the IdP and SP. This algorithm must be the same on the IdP profile and the SP profile.
- **Digest Method:** Algorithm used to verify the integrity of the Assertions between IdP and SP. This parameter must be the same on the IdP profile and the SP profile.
- **Attribute 1:** Name of the attribute in SAML assertion whose value must be extracted and stored as attribute1. A similar pattern is applicable to the remaining attributes as well.
- **Attribute1 Expression:** Expression that is evaluated to obtain attribute 1's value.
- **Attribute1 Format:** Format of attribute 1 to be sent in the SAML assertion.
- **Attribute1 Friendly Name:** Name of attribute 1 that must be sent in the SAML assertion.

2. Configure the SAML authentication policy and associate the SAML IdP profile as the action of the policy.

   a. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > SAML IDP**.

   b. On the **Policies** tab, click **Add**, enter the values for the following parameters, and click **Create**.

   Parameter descriptions:

   - **Name:** Name of the SAML IdP authentication policy.
   - **Action:** Name of the SAML IdP profile to apply to requests or connections that match this policy.
   - **Log Action:** Name of message log action to use when a request matches this policy. Select a log action from the drop-down list or create a log action by clicking **Add**.
   - **Undefined-Result Action:** Action to perform if the result of a policy evaluation is undefined. An undefined event indicates an internal error condition. Only the built-in actions can be used.
   - **Expression:** Expression, which is evaluated to choose a profile for authentication.
   - **Comments:** Any comments to preserve information about this policy.

3. Associate the SAML IdP policy with an authentication virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and bind the SAML IdP policy with the authentication virtual server.

Configure SAML single sign-on

To provide single sign-on capabilities across applications that are hosted on the service provider, you can configure SAML single sign-on on the SAML SP.

Configuring SAML single sign-on by using the CLI

1. Configure the SAML SSO profile.

   Example

   In the following command, Example is the load balancing virtual server that has a web link from the SharePoint portal. Nssp.example.com is the Traffic Management virtual server that is load balancing the SharePoint server.

   ```
   add tm samlSSOProfile tm-saml-sso -samlSigningCertName nssp
   -assertionConsumerServiceURL "https://nssp2.example.com/cgi/samlauth"
   -relaystateRule "\\"https://nssp2.example.com/samlsso.html\\""
   -sendPassword ON -samlIssuerName nssp.example.com
   ```

2. Associate the SAML SSO profile with the traffic action.

   Example

   The following command enables SSO and binds the SAML SSO profile created above to a traffic action.

   ```
   add tm trafficAction html_act -SSO ON -samlSSOProfile tm-saml-sso
   ```

3. Configure the traffic policy that specifies when the action must be run.

   Example

   The following command associates the traffic action with a traffic policy.

   ```
   add tm trafficPolicy html_pol "HTTP.REQ.URL.CONTAINS(\\"abc.html\\")"
   html_act
   ```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Bind the traffic policy created previously to a traffic management virtual server (load balancing or content switching). Alternatively, the traffic policy can be associated globally.

   NOTE:

   - This traffic management virtual server must be associated with the relevant authentication virtual server that is associated with the SAML action.
   - In an nFactor setup, an authentication virtual server, which is redirected by a load balancer, cannot act as the identity provider for the back-end application.

   ```
   bind lb vserver lb1_ssl -policyName html_pol -priority 100
   -gotoPriorityExpression END -type REQUEST
   ```

Configuring SAML single sign-on by using the GUI

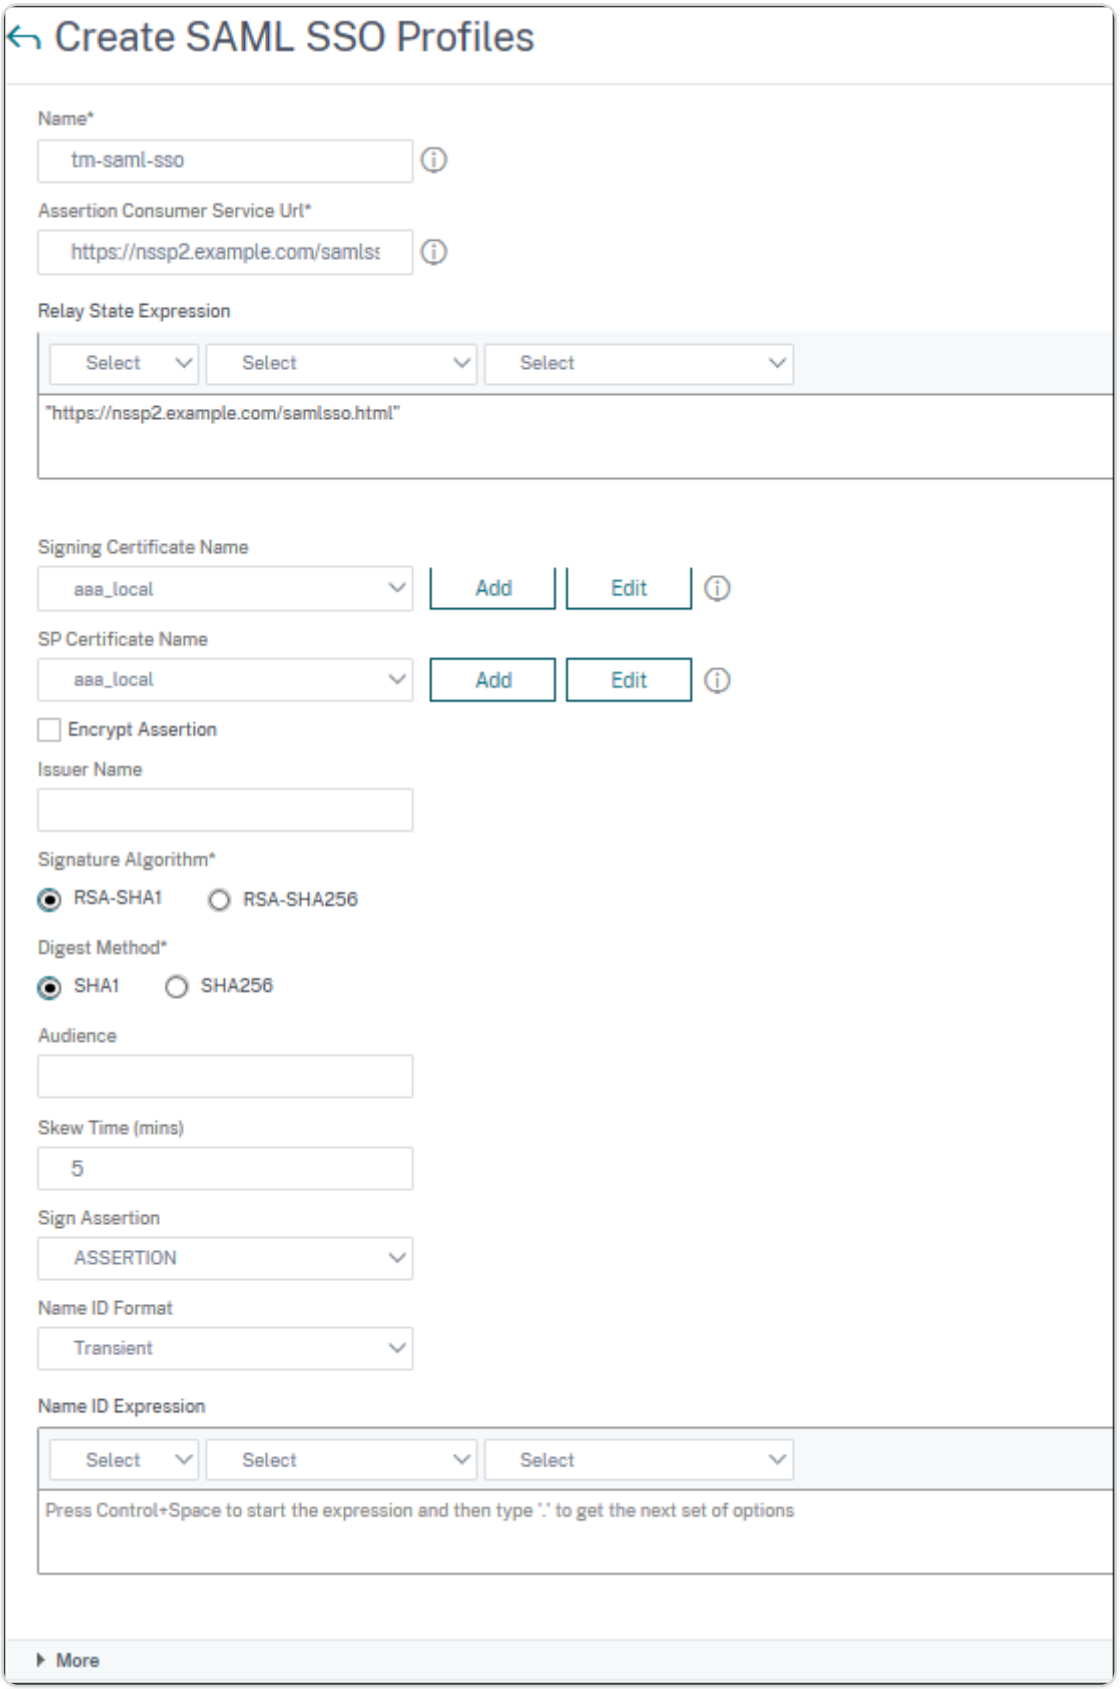
To configure SAML single sign-on you need to define the SAML SSO profile, the traffic profile, and the traffic policy and bind the traffic policy to a traffic management virtual server or globally to the NetScaler appliance.

1. Navigate to **Security > AAA-Application Traffic > Policies > Traffic > SAML SSO Profiles** and click **Add**.
2. On the **Create SAML SSO Profiles** page, enter the values for the following fields and click **Create**.
   - **Name:** Name for the SAML SSO profile.
   - **Assertion Consumer Service Url:** URL to which the assertion must be sent.
   - **Signing Certificate Name:** Name of the SSL certificate that is used to sign assertion.
   - **SP Certificate Name:** Name of the SSL certificate of a peer or receiving party using which the assertion is encrypted.
   - **Issuer Name:** The name to be used in requests sent from NetScaler to IdP to uniquely identify NetScaler.
   - **Signature Algorithm:** Algorithm to be used to sign or verify SAML transactions.
   - **Digest Method:** Algorithm to be used to compute or verify digest for SAML transactions.
   - **Audience:** Audience for which an assertion sent by IdP is applicable. This is typically an entity name or url that represents a service provider.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Skew Time (mins):** The number of minutes on either side of the current time that the assertion is valid.
- **Sign Assertion:** Option to sign portions of assertion when NetScaler IdP sends one. Based on the user selection, either **ASSERTION** or **RESPONSE** or **BOTH** or **NONE** can be signed.
- **Name ID Format:** Format of NameIdentifier sent in assertion.
- **Name ID Expression:** Expression that is evaluated to obtain NameIdentifier to be sent in assertion.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

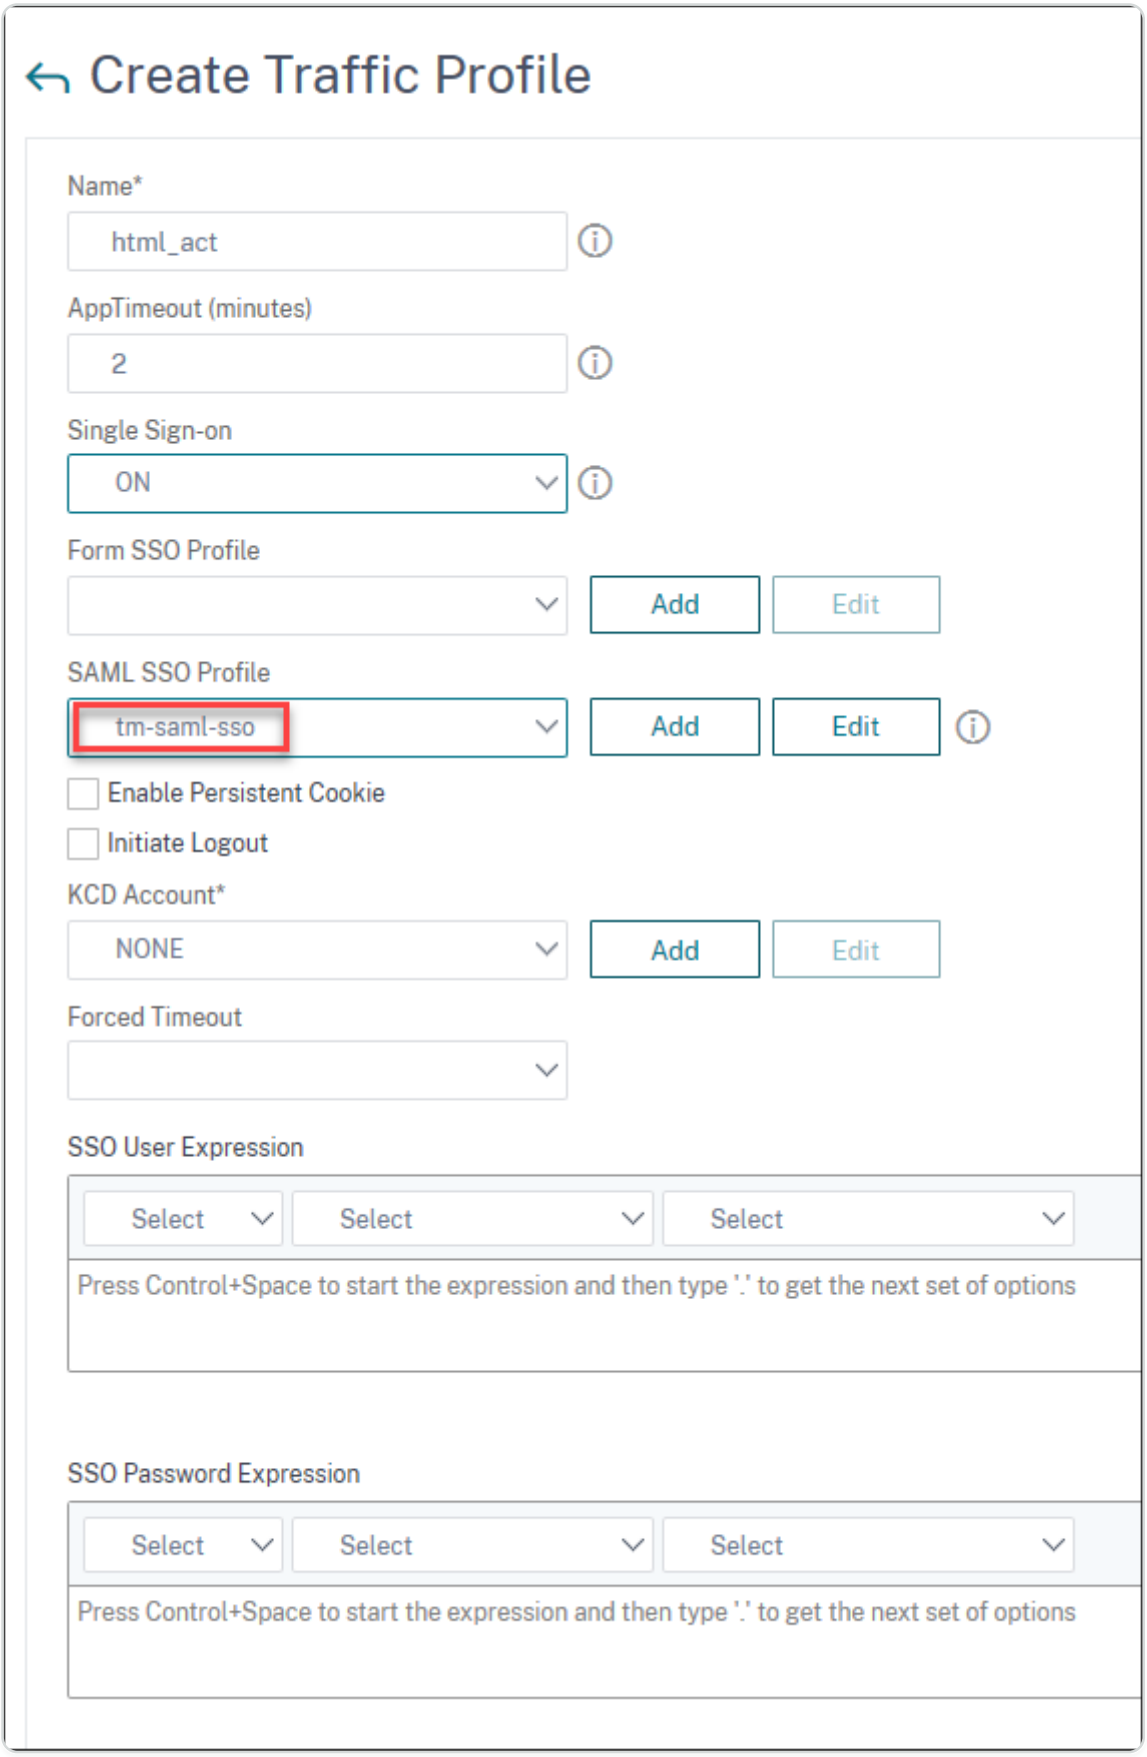


3. Navigate to **Security > AAA-Application Traffic > Policies > Traffic > Traffic Profiles** and click **Add**.
4. On the **Create Traffic Profile** page, enter the values for the following fields, and click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Name:** Name for the traffic action.
- **AppTimeout (minutes):** Time interval, in minutes, of user inactivity after which the connection is closed.
- **Single Sign-on:** Select **ON**.
- **SAML SSO Profile:** Select the created SAML SSO profile.
- **KCD Account:** Kerberos constrained delegation account name.
- **SSO User Expression:** Expression that is evaluated to obtain user name for SingleSignOn.
- **SSO Password Expression:** Expression that is evaluated to obtain password for SingleSignOn

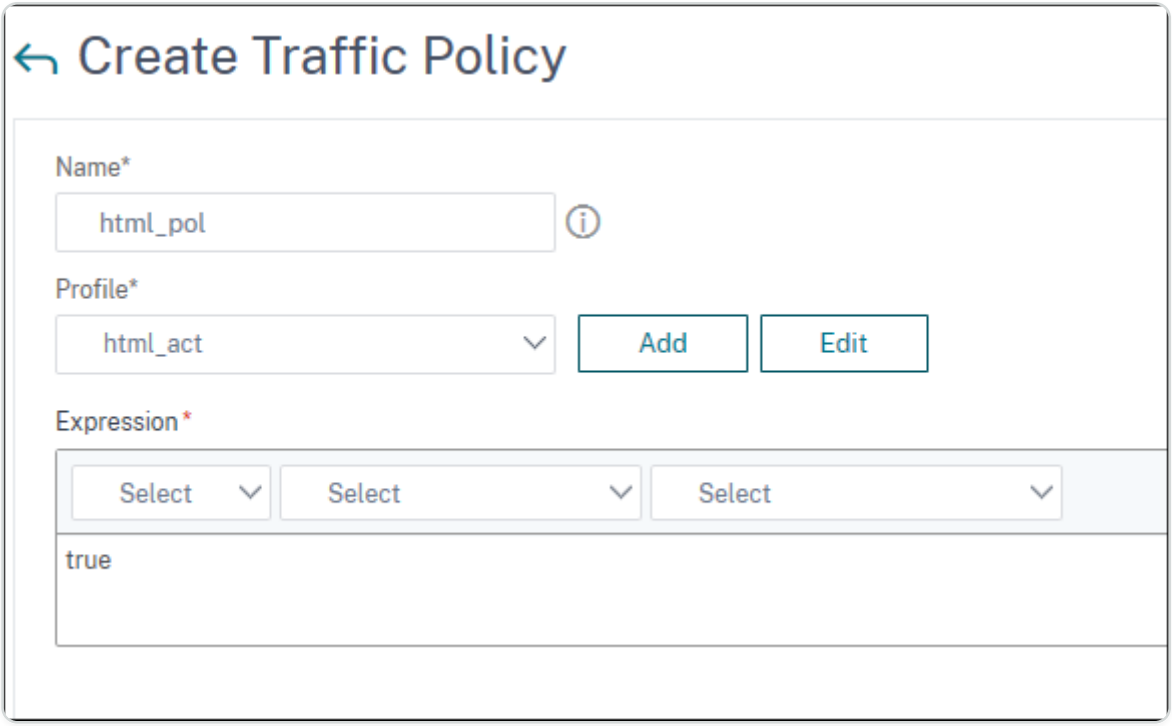
© 1997–2026 Citrix Systems, Inc. All rights reserved.



5. Navigate to **Security > AAA-Application Traffic > Policies > Traffic > Traffic Policies** and click **Add**.
6. On the **Create Traffic policy** page, enter the values for the following, and click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Name:** Name of the traffic policy to be created.
- **Profile:** Select the created traffic profile.
- **Expression:** Advanced policy expression that the policy uses to respond to specific request. For example, true.



7. To bind the traffic policy to a traffic management virtual server, navigate to **Traffic Management > Load Balancing > Virtual Servers**, select a virtual server, and click **Edit**.
8. Under **Advanced Settings**, click **Policies**.
9. Select **Traffic** in the **Choose Policy** field, select **Request** in the **Choose Type** field, and click **Continue**.
10. Under **Select Policy**, click to select the created traffic.
11. Click **Select**.
12. Click **Bind** to bind the traffic policy to the virtual server.

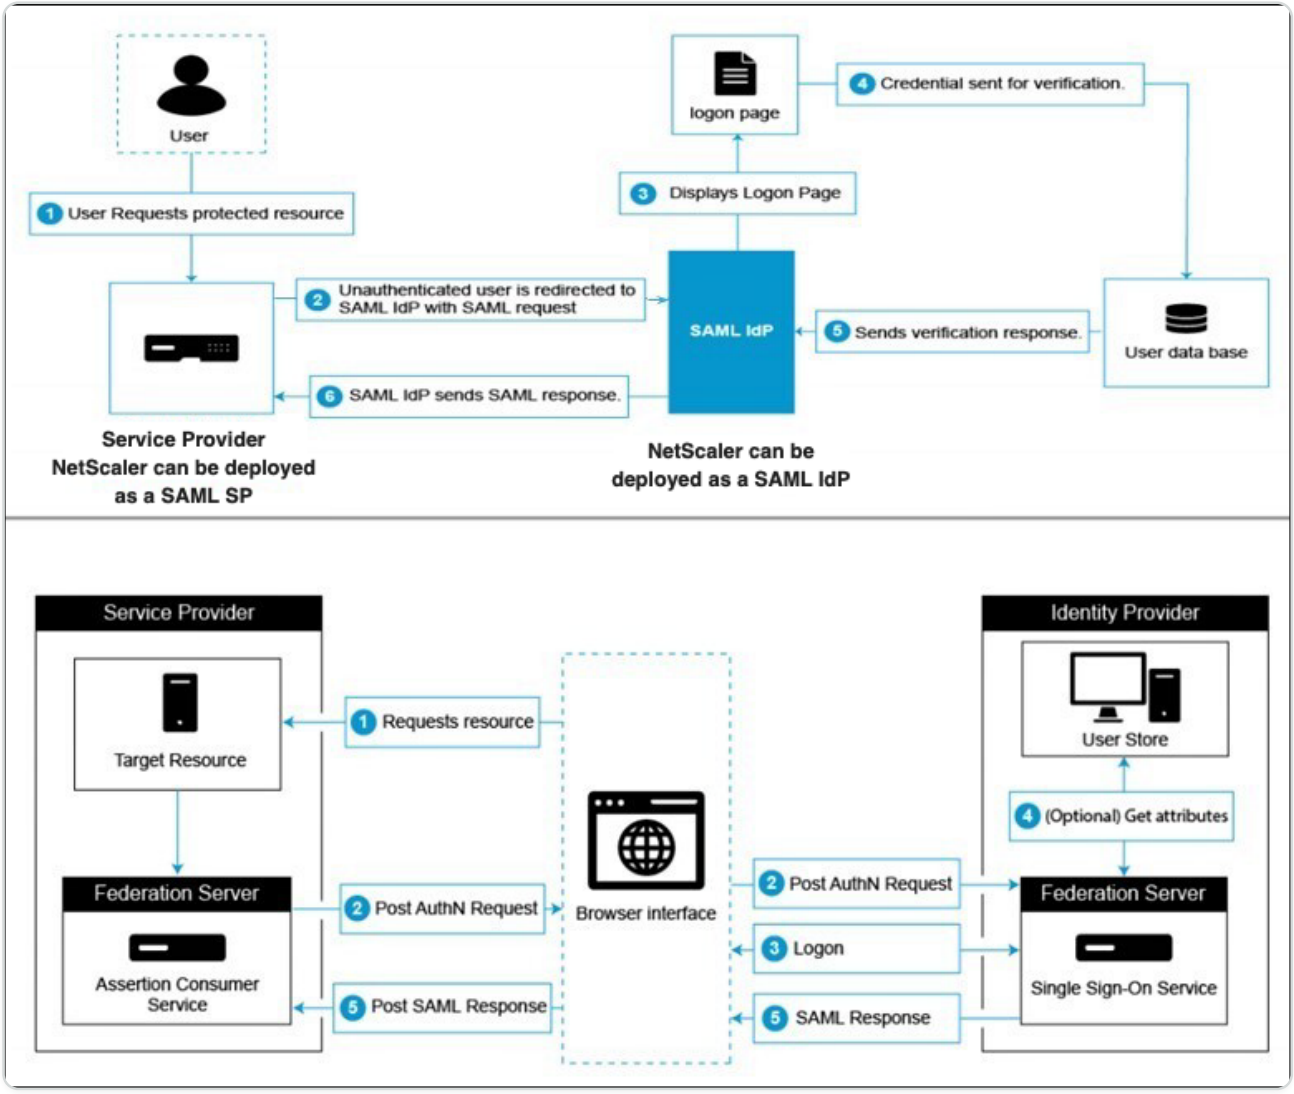
Configure Microsoft Entra ID as SAML IdP and NetScaler as SAML SP

The SAML service provider (SAML SP) is a SAML entity that is deployed by the service provider. When a user tries to access a protected application, the SP evaluates the client request. If the client is unauthenticated (does not have a valid NSC_TMAA or NSC_TMAS cookie), the SP redirects the request to the SAML identity provider (IdP). The SP also validates SAML assertions that are received from the IdP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The SAML identity provider (SAML IdP) is a SAML entity that is deployed on the customer network. The IdP receives requests from the SAML SP and redirects users to a logon page, where they must enter their credentials. The IdP authenticates these credentials with the user directory (external authentication server, such as LDAP) and then generates a SAML assertion that is sent to the SP. The SP validates the token, and the user is then granted access to the requested protected application.

The following diagram depicts the SAML authentication mechanism.

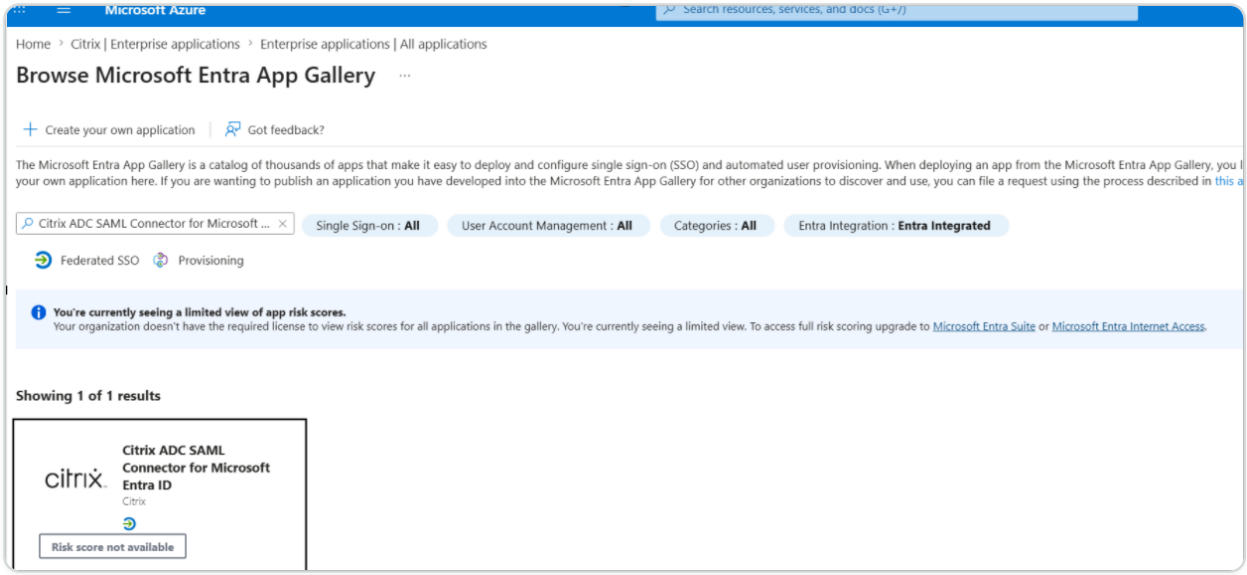


Microsoft Entra ID side configurations

Configure single sign-on settings:

1. On the Azure portal, click **Azure Active Directory**.
2. Under the **Manage** section in the navigation pane, click **Enterprise Applications**. A random sample of the applications in your Microsoft Entra ID (formerly Azure AD) tenant appears.
3. In the search bar, enter **Citrix ADC SAML Connector for Microsoft Entra ID**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



4. Under the **Manage** section, select **Single sign-on**.
5. Select **SAML** to configure single sign-on. The **Set up Single Sign-On with SAML - Preview** page appears. Here, Azure is acting as a SAML IdP.
6. **Configure basic SAML options:**

   Identifier (Entity ID) - Required for some apps. Uniquely identifies the application for which the single sign-on is being configured. Microsoft Entra ID sends the identifier to the application as the audience parameter of the SAML token. The application is expected to validate it. This value also appears as the Entity ID in any SAML metadata provided by the application.

   Reply URL - Mandatory. Specifies where the application expects to receive the SAML token. The reply URL is also referred as the Assertion Consumer Service (ACS) URL. Specify the reply URL in the format `http(s)://<SP_URL>/cgi/samlauth`.

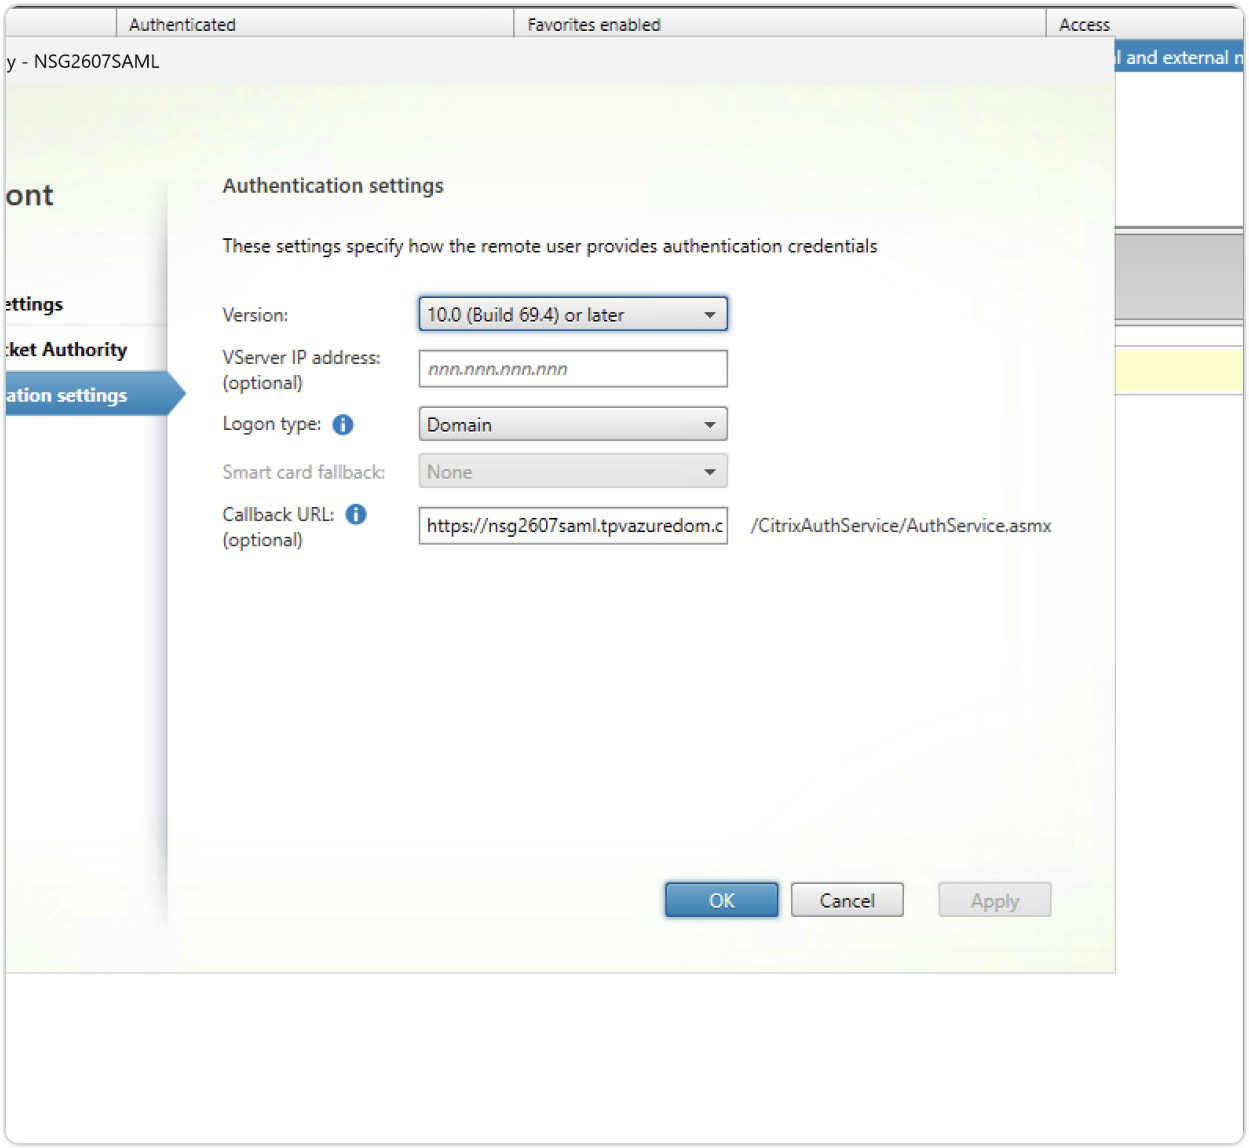
   Sign-on URL - When a user opens this URL, the service provider redirects to Microsoft Entra ID to authenticate and sign on the user.

   NOTE:

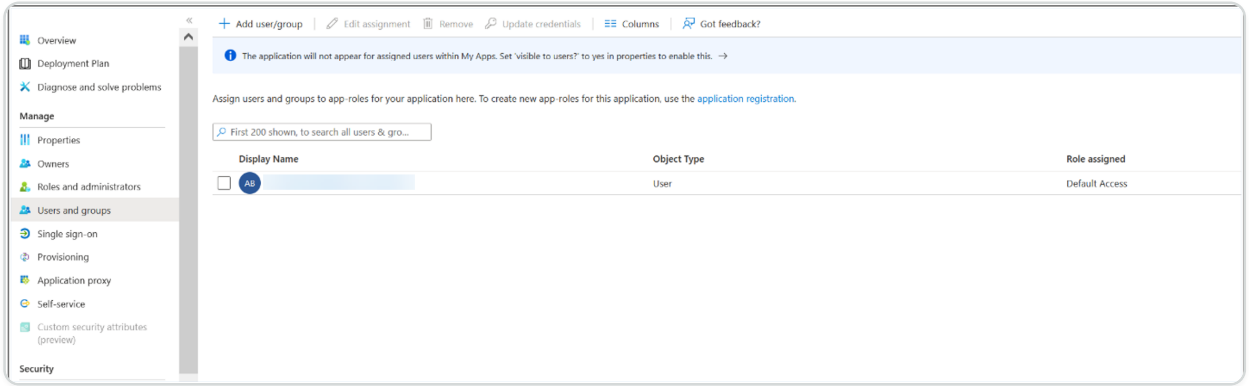
   When the deployment includes StoreFront or ICA (Citrix Virtual Apps and Desktops), set the Sign-on URL to the CitrixAuthService endpoint. For example, `https://<YOUR_FQDN>/CitrixAuthService/AuthService.asmx`.

   Relay State - Specifies to the application where to redirect the user after the authentication is complete.
7. Download the certificate (Base64) from the **SAML Certificates** section. The certificate is used as samlidPCertName while configuring NetScaler as SAML SP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



8. Once the Microsoft Entra ID side configuration is completed, add users and user groups that are permitted to access the application. Navigate to the **Users and groups** tab and click **+Add user/group**.



NetScaler side configurations

1. Create a SAML action.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

a. Navigate to **NetScaler® Gateway > Policies > Authentication > SAML**.

b. On the **Policies** tab, click **Add**.

c. In the **Name** field, specify a policy name.

d. Click the **Add** button next to **Server**, enter values for the following parameters, and click **Create**.

Parameter description:

The value for **Redirect URL** and **IDP Certificate Name** parameters must be taken from the Azure side configurations.

- **Name:** Name of the server.
- **Export SAML Metadata:** Click this link if you want to export the metadata of the SAML profile to a NetScaler Gateway VPN virtual server.
- **Import Metadata:** This option imports the SAML metadata. This option is enabled by default.
  - If the **Import Metadata** option is disabled, enter the values for the following parameters:
    - **Redirect URL:** Enter the login URL used previously in the Microsoft Entra ID "Setup NetScaler" section. For example, `https://login.microsoftonline.com/3e6d1786-4e0c-4c70-86d2-ae7811f97f79/saml2`.
    - **Single Logout URL:** URL on IdP to which logoutRequest is sent on NetScaler session cleanup. For example, `https://login.microsoftonline.com/3e6d1786-4e0c-4c70-86d2-ae7811f97f79/saml2`.
    - **SAML Binding:** A mechanism that is used to transport SAML requestor and responder messages between the SP and IdP. When NetScaler acts as an SP, it supports **POST**, **REDIRECT**, and **ARTIFACT** bindings. The default binding method is **POST**.
    - **Logout Binding:** Specifies the transport mechanism of SAML logout messages. The default binding mechanism is **POST**.
    - **IDP Certificate Name:** IdPCert Certificate (Base64) present in the **SAML Certificates** section.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add ssl certkey <IDP-CERT-NAME> -cert <Name-of-the-IdP-certificate-downloaded-above>
```

- **User Field:** The "userprincipalName" taken from the “User Attributes and Claims” section of Azure IdP.
- **Signing Certificate Name:** Not needed for Microsoft Entra ID. Select the SAML SP certificate (with private key) that NetScaler uses to sign authentication requests to the IdP. The same certificate (without private key) must be imported to the IdP, so that the IdP can verify the authentication request signature. This field is not needed for most IdPs.
- **Issuer Name:** Entity ID or the identifier. `https://gateway.nssvctesting.net` in this case. In a load balancing deployment scenario, you must use the FQDN of the load balancing virtual server.
- **Reject Unsigned Assertion:** Option that you can specify if you require the assertions from the IdP to be signed. The default option is **ON**.
- **Audience:** Audience for which the assertion sent by IdP is applicable. This parameter is typically an entity name or URL that represents the service provider.
- **Signature Algorithm:** Algorithm to be used to sign or verify SAML transactions. The default value is **RSA-SHA256**.
- **Digest Method:** Algorithm to be used to compute or verify digest for SAML transactions. The default value is **SHA256**.
- **Default Authentication Group:** The default group that is chosen when the authentication succeeds in addition to the extracted groups.
- **Group Name Field:** Name of the tag in an assertion that contains user groups.
- **Skew Time (mins)"** This option specifies the clock skew in minutes that the NetScaler service provider allows on an incoming assertion. For example, if you set the skew time to 10 minutes at 16:00, the SAML assertion is valid from 15:50 to 16:10 - 20 minutes in total. The default skew time is 5 minutes.
- **Two Factor:** This parameter enables the second factor after SAML. Default value: **OFF**.
- **Requested Authentication Context:** This parameter specifies the authentication context requirements of authentication statements returned in the response. Default value: **Exact**.
- **Authentication Class Types:** This parameter specifies the authentication class types that are requested from IdP. The default value is none.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Send Thumbprint:** This parameter is used to send thumbprint instead of x509 certificate in SAML request. This option is disabled by default.
- **Enforce Username:** This parameter is used to choose whether the user name that is extracted from the SAML assertion can be edited in the login page while doing the second factor. This option is enabled by default.
- **Force Authentication:** This parameter forces authentication at the IdP that receives NetScaler's request. This option is disabled by default
- **Store SAML Response:** This parameter is used to store the entire SAML response through the life of the user session. This option is disabled by default.

2. Create a corresponding SAML policy for the SAML action.

   a. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy** and click **Add**.

   b. On the **Create Authentication Policy** page, provide the following details:

      - **Name:** Specify a name for the SAML policy.
      - **Action Type:** Select **SAML** as the authentication action type.
      - **Action:** Select the SAML server profile to bind the SAML policy with.
      - **Expression:** Displays the name of the rule or expression that the SAML policy uses to determine if the user must authenticate with the SAML server. On the text box, set the value “rule = true” for the SAML policy to take effect and the corresponding SAML action to be run.

3. Bind the SAML policy to the VPN virtual server and link the VPN virtual server to the authentication virtual server through an authentication profile. For details on the binding procedure, see Bind the authentication policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTES:

- Microsoft Entra ID does not expect the **Subject ID** field in the SAML request.
- For NetScaler to not send the **Subject ID** field, type the following command on the NetScaler CLI. `nsapimgr_wr.sh -ys call="ns_saml_dont_send_subject"` This command is only applicable in nFactor authentication workflows.
- Add `nsapimgr_wr.sh -ys call="ns_saml_dont_send_subject"` command in the /nsconfig/rc.netscaler file for persistency and also to take effect upon rebooting.

More features supported for SAML

The following features are supported for SAML.

Metadata reading and generation support for SAML SP and IdP configuration

NetScaler appliance now supports metadata files as means of configuration entities for both SAML Service Provider (SP) and Identity Provider (IdP). The metadata file is a structured XML file that describes the configuration of an entity. The metadata files for SP and IdP are separate. Based on deployment, and at times, one SP, or IdP entity can have multiple metadata files. As an administrator, you can export and import (SAML SP and IdP) metadata files on NetScaler. The functionality of metadata export and import for SAML SP and IdP is explained in the following sections.

Metadata export for SAML SP

Consider an example where the NetScaler is configured as SAML SP and an SAML IdP would like to import metadata that contains the NetScaler SP configuration. Assume that the NetScaler appliance is already configured with a "samlAction" attribute that specifies SAML SP configuration.

To export metadata from users or administrator, query the NetScaler Gateway or authentication virtual server in the following format:

```
https://vserver.company.com/metadata/samlsp/&lt;action-name>
```

Starting from 14.1-29.x, NetScaler as a SAML SP can support multiple certificates from the same IdP. This functionality allows the SP to select the correct certificate and validate SAML assertions from the IdP by using that certificate. The SP can store up to 4 certificates.

The following command displays the configuration of the SAML action:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
show authentication samlaction SAMLSPAct1

   Name: SamlSPAct1

    User field:

    IdPCert:

    SigningCert : ns-sftrust-certificate

    IssuerName :

    Redirect Url:

    Single Logout Url:

    Reject unsigned assertion: ON

    Two factor: OFF

    Signature Method: RSA-SHA256

    Digest Method: SHA256

    SAML Binding: POST

    Send Thumbprint: OFF

    Enforce Username: ON

    Skew Time: 5

    Requested Authentication Context: exact

    Authentication Class Reference: None

    Logout Binding: POST

    Force Authentication: OFF

    Metadata Import URL: https://&lt;idp meta-data url>

    Metadata Import Refresh Interval: 3600
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
    Preferred bind type: SSOREDIRECT

    Store SAML Response: OFF
```

Metadata import for SAML SP

Currently, the SAML Action configuration on the NetScaler appliance takes various parameters. The administrator manually specifies these parameters. However, administrators are often unaware of nomenclature if it comes to interop with different SAML systems. If metadata of IdP is available, then a bulk of the configuration in the 'samlAction' entity can be avoided. In fact, the entire IdP specific configuration might be omitted if IdP metadata file is given. The 'samlAction' entity now takes an extra parameter to read configuration from metadata file.

When you import a metadata in a NetScaler appliance, the metadata does not contain any signature algorithms to be used, it contains the endpoint details. A metadata can be signed with certain algorithms which can be used to verify the metadata itself. The algorithms are not stored in the 'samlAction' entity.

Therefore, what you specify in the 'samlAction' entity are the ones used when sending the data out. An incoming data can contain a different algorithm for a NetScaler appliance to process.

You can import a maximum size of 64 K bytes of metadata.

To fetch the metadata files by using command line interface.

```
set samlAction &lt;name> [-metadataUrl &lt;url> [-metadataRefreshInterval
&lt;int>] https://idp.citrix.com/samlidp/metadata.xml
```

NOTE

The metadataRefreshInterval parameter is the interval in minutes for fetching metadata information from the specified metadata URL. Default value 36000.

Metadata import for SAML IdP

The "samlIdPProfile" parameter takes a new argument to read the entire configuration that is specific to SP. SAML IdP configuration can be simplified by replacing SP specific properties with an SP metadata file. This file is queried through HTTP.

To read from metadata file using command line interface:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set samlIdPProfile &lt;name> [-metadataUrl &lt;url>] [-
metadataRefreshInterval &lt;int>]
```

Name-value attribute support for SAML authentication

You can now configure SAML authentication attributes with a unique name along with values. The names are configured in the SAML action parameter and the values are obtained by querying for the names. By specifying the name attribute value, admins can easily search for the attribute value associated with the attribute name. Also, admins no longer have to remember the attribute by its value alone.

IMPORTANT

- In samlAction command, you can configure a maximum of 64 attributes separated by comma with total size less than 2048 bytes.
- Citrix® recommends that you use the attributes list. Use of "attribute 1 to attribute 16" will cause session failure if the extracted attribute size is large.

To configure the name-value attributes by using the CLI

At the command prompt, type:

```
add authentication samlAction &lt;name> [-Attributes &lt;string>]
```

Example:

```
add authentication samlAction samlAct1 -attributes
“mail,sn,userprincipalName”
```

Assertion Consumer Service URL support for SAML IdP

A NetScaler appliance configured as a SAML Identity Provider (IdP) now supports Assertion Consumer Service (ACS) indexing to process SAML Service Provider (SP) request. The SAML IdP imports ACS indexing configuration from SP metadata or allows for entering ACS indexes information manually. The following table lists some articles that are specific to deployments where the NetScaler appliance is used as a SAML SP or a SAML IdP.

Some information on other specific deployments:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- NetScaler as SAML SP on FIPS Device
- Configuring Office365 for single sign-on with NetScaler as SAML IdP

Increase of SessionIndex size in SAML SP

The SessionIndex size of the SAML Service Provider (SP) is increased to 96 bytes. Previously, the default maximum size of SessionIndex was 63 bytes.

NOTE

Support introduced in NetScaler 13.0 Build 36.x

Custom authentication class reference support for SAML SP

You can configure custom authentication class reference attribute in the **SAML action** command. Using the custom authentication class reference attribute, you can customize the class names in the appropriate SAML tags. The custom authentication class reference attribute along with namespace is sent to the SAML IdP as part of SAML SP authentication request.

Previously, using SAML action command, you might configure only a set of predefined classes defined in authnCtxClassRef attribute.

IMPORTANT

While configuring customAuthnCtxClassRef attribute, ensure the following:

- The names of the classes must include alphanumeric characters or a valid URL with proper XML tags.
- If you have to configure multiple custom classes, each class must be separated by commas

To configure the customAuthnCtxClassRef attributes by using the CLI

At the command prompt, type:

- add authentication samlAction `<name>`
- set authentication samlAction `<name>`

Example:

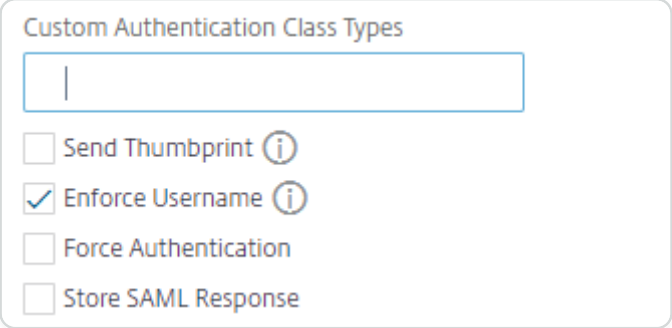
- `add authentication samlAction samlact1 –customAuthnCtxClassRef http://www.class1.com/LoA1,http://www.class2.com/LoA2`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `set authentication samlAction samlact2 –customAuthnCtxClassRef http://www.class3.com/LoA1,http://www.class4.com/LoA2`

To configure the customAuthnCtxClassRef attributes by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > SAML**.
2. On the SAML page, select **Servers** tab and Click **Add**.
3. On the **Create Authentication SAML Server** page, enter the name for SAML action.
4. Scroll down to configure the class types in **Custom Authentication Class Types** section.



Support for artifact binding in SAML IdP

NetScaler appliance configured as SAML Identity Provider (IdP) supports artifact binding. The artifact binding enhances the security of SAML IdP and restricts the malicious users from inspecting the assertion.

Assertion Consumer Service URL support for SAML IdP

A NetScaler appliance configured as a SAML Identity Provider (IdP) now supports Assertion Consumer Service (ACS) indexing to process SAML Service Provider (SP) request. The SAML IdP imports ACS indexing configuration from SP metadata or allows for entering ACS indexes information manually.

FIPS offload support

A NetScaler MPX FIPS appliance used as a SAML service provider now supports encrypted assertions. Also, a NetScaler MPX FIPS appliance functioning as a SAML service provider or a SAML identity provider can now be configured to use the SHA2 algorithms on FIPS hardware.

NOTE

In FIPS mode, only the RSA-V1_5 algorithm is supported as key transport algorithm.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configuring FIPS offload support using the command line interface:

1. Add SSL FIPS

   add ssl fipsKey fips-key

2. Create a CSR and use it at CA server to generate a certificate. You can then copy the certificate in **/nsconfig/ssl**. Let's assume that the file is *fips3cert.cer*.

   ```
   add ssl certKey fips-cert -cert fips3cert.cer -fipsKey fips-key
   ```

3. Specify this certificate in the SAML action for SAML SP module

   ```
   set samlAction <name> -samlSigningCertName fips-cert
   ```

4. Use the certificate in samlIdpProfile for SAML IdP module

   ```
   set samlidpprofile fipstest –samlIdpCertName fips-cert
   ```

Common SAML terminologies

The following are some common SAML terminologies:

- **Assertion:** A SAML assertion is an XML document returned by the Identity Provider to the Service Provider after authentication of the user. The assertion has a specific structure, as defined by the SAML standard.
- **Types of Assertions:** The following are the types of assertion.
  - Authentication - the user is authenticated by a particular means at a particular time
  - Authorization - the user was granted or denied access to a specified resource
  - Attributes - the user is associated with the supplied attributes
- **Assertion Consumer Service (ACS):** The service provider's endpoint (URL) that is responsible for receiving and parsing a SAML assertion
- **Audience Restriction:** A value within the SAML assertion that specifies who (and only who) the assertion is intended for. The "audience" will be the service provider and is typically a URL but can technically be formatted as any string of data.
- **Identity Provider (IdP):** In terms of SAML, the Identity Provider is the entity that verifies the identity of the user, in response to a request by the Service Provider.

  The Identity Provider is responsible for maintaining and authenticating the user's identity

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Service Provider (SP):** In terms of SAML, the Service Provider (SP) offers a service to the user and allows the user to sign in by using SAML. When the user attempts to sign in, the SP sends a SAML authentication request to the Identity Provider (IdP)
- **SAML Binding:** SAML requestors and responders communicate by exchanging messages. The mechanism to transport these messages is called a SAML binding.
- **HTTP Artifact:** One of the binding options supported by the SAML protocol. HTTP Artifact is useful in scenarios where the SAML requester and responder are using an HTTP User-Agent and do not want to transmit the entire message, either for technical or security reasons. Instead, a SAML Artifact is sent, which is a unique ID for the full information. The IdP can then use the Artifact to retrieve the full information. The artifact issuer must maintain state while the artifact is pending. An Artifact Resolution Service (ARS) must be set up.

  HTTP Artifact sends the artifact as a query parameter.
- **HTTP POST:** One of the binding options supported by the SAML protocol.

  HTTP POST sends the message content as a POST parameter, in the payload.
- **HTTP Redirect:** One of the binding options supported by the SAML protocol.

  When HTTP Redirect is used, the Service Provider redirects the user to the Identity Provider where the login happens, and the Identity Provider redirects the user back to the Service Provider. HTTP Redirect requires intervention by the User-Agent (the browser).

  HTTP Redirect sends the message content in the URL. Because of this, it cannot be used for the SAML response, because the size of the response will typically exceed the URL length allowed by most browsers.

  NOTES:

  - The NetScaler appliance supports POST and Redirect bindings during logout.
  - The `ns_aaa_trusted_redirect_hosts` is a pattern set allow list used for SAML logout redirect validation before redirecting the user to the unknown hosts. During SAML logout, the `RelayState` parameter might contain a redirect URL where the user must be sent after logout completes. For enhanced security, the admins can use the ns_aaa_trusted_redirect_hosts pattern set to validate the redirect URL.
- Metadata: Metadata is the configuration data in SP and IdP to know how to communicate to each other which will be in XML standards

© 1997–2026 Citrix Systems, Inc. All rights reserved.

OAuth authentication

The authentication, authorization, and auditing traffic management feature supports OAuth and OpenID Connect (OIDC) authentication. It authorizes and authenticates users to services that are hosted on applications such as Google, Facebook, and Twitter.

Points to note

- NetScaler Advanced Edition and higher is required for the solution to work.
- A NetScaler appliance must be on version 12.1 or later for the appliance to work as an OAuth IdP using OIDC.
- OAuth on a NetScaler appliance is qualified for all SAML IdPs that are compliant with "OpenID connect 2.0".

A NetScaler appliance can be configured to behave as a Service Provider (SP) or an Identity Provider (IdP), using SAML and OIDC. Previously, a NetScaler appliance configured as IdP supported only SAML protocol. Starting from NetScaler 12.1 version, NetScaler supports the OIDC as well.

OIDC is an extension to OAuth authorization/delegation. A NetScaler appliance supports OAuth and OIDC protocols in the same class of other authentication mechanisms. OIDC is an add-on to OAuth as it provides a way for getting user information from the authorization server as opposed to OAuth that gets only a token which cannot be gleaned for user information.

The authentication mechanism facilitates the inline verification of OpenID tokens. A NetScaler appliance can be configured to obtain certificates and verify signatures on the token.

A major advantage of using the OAuth and OIDC mechanisms is that the user information is not sent to the hosted applications. Therefore, the risk of identity theft is considerably reduced.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The NetScaler appliance configured for authentication, authorization, and auditing now accepts incoming tokens that are signed using the HMAC HS256 algorithm. In addition, the public keys of the SAML Identity Provider (IdP) are read from a file, instead of learning from a URL endpoint.

In the NetScaler implementation, the application is accessed by the authentication, authorization, and auditing traffic management virtual server. So, to configure OAuth, you must configure an OAuth policy which must then be associated with an authentication, authorization, and auditing traffic management virtual server.

Configure the OpenID Connect protocol

A NetScaler appliance can now be configured as an identity provider by using OIDC protocol. OIDC protocol strengthens the identity providing capabilities of the NetScaler appliance. You can now access the enterprise wide hosted application with a single sign-on. The OIDC offers more security by not transferring user password but works with tokens with specific lifetime. OIDC also is designed to integrate with non-browser clients such as apps and services. Therefore, many implementations adopt OIDC widely.

Advantages of having the OpenID Connect support

- OIDC eliminates the overhead of maintaining multiple authentication passwords as the user has a single identity across the organization.
- OIDC provides a robust security for your password as the password is shared only with your identity provider and not with any application you access.
- OIDC has vast interoperability with various systems making it easier for the hosted applications to accept OpenID.
- OIDC is a simple protocol that enables native clients to easily integrate with servers.

To configure a NetScaler appliance as an IdP using the OpenID Connect protocol by using GUI

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies > Authentication > Advanced Policies > OAuth IdP**.
2. Click **Profile** and click **Add.**

   On the **Create Authentication OAuth IDP Profile** screen, set values for the following parameters and click **Create**.

   - **Name** – Name of the authentication profile.
   - **Client ID** – Unique string that identifies SP.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Client Secret** – Unique secret that identifies SP.
- **Redirect URL** – Endpoint on SP to which code/token has to be posted.
- **Issuer Name** – String that identifies IdP.
- **Audience** – Target recipient for the token being sent by IdP. This might be checked by the recipient.
- **Skew Time** – The time for which the token remains valid.
- **Default Authentication Group** – A group added to the session for this profile to simplify policy evaluation and help in customizing policies.

3. Click **Policies** and click **Add.**
4. On the **Create Authentication OAuth IDP Policy** screen, set values for the following parameters and click **Create**.

- **Name –** The name of the authentication policy.
- **Action** – Name of profile created earlier.
- **Log Action** –Name of message log action to use when a request matches this policy. Not a mandatory filed.
- **Undefined-Result Action** – Action to perform if the result of policy evaluation is undenfined(UNDEF). Not a mandatory field.
- **Expression** – Advanced policy expression that the policy uses to respond to specific request. For example, true.
- **Comments** – Any comments about the policy.

Binding the OAuthIdP policy and LDAP policy to the authentication virtual server

1. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Actions > LDAP**.
2. On **LDAP Actions** screen, click **Add**.
3. On **Create Authentication LDAP Server** screen, set the values for the following parameters, and click **Create**.

- **Name –** The name of the LDAP action
- **ServerName/ServerIP –** Provide FQDN or IP of the LDAP server
- Choose appropriate values **for Security Type, Port, Server Type, Time-Out**

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Make sure **Authentication** is checked
- **Base DN –** Base from which to start LDAP search. For example, dc=aaa,dc=local.
- **Administrator Bind DN:** User name of the bind to LDAP server. For example, admin@aaa.local.
- **Administrator Password/Confirm Password: Password to bind LDAP**
- Click **Test Connection** to test your settings.
- **Server Logon Name Attribute:** Choose **“sAMAccountName”**
- Other fields are not mandatory and hence can be configured as required.

4. Navigate to **Configuration > Security > AAA-Application Traffic > Policies >Authentication > Advanced Policies > Policy.**
5. On **Authentication Policies** screen, click **Add**.
6. On **Create Authentication Policy** page, set the values for the following parameters, and click **Create.**

   - **Name –** Name of the LDAP Authentication Policy.
   - **Action Type –** Choose **LDAP.**
   - **Action –** Choose the LDAP action.
   - **Expression –** Advanced policy expression that the policy uses to respond to specific request. For example, true**.

To configure the NetScaler appliance as an IdP using the OpenID Connect protocol by using CLI

At the command prompt, type the following commands:

- `add authentication OAuthIDPProfile <name> [-clientID <string>][-clientSecret ][-redirectURL <URL>][-issuer <string>][-audience <string>][-skewTime <mins>] [-defaultAuthenticationGroup <string>]`
- `add authentication OAuthIdPPolicy <name> -rule <expression> [-action <string> [-undefAction <string>] [-comment <string>][-logAction <string>]`
- `add authentication ldapAction aaa-ldap-act -serverIP 10.0.0.10 -ldapBase "dc=aaa,dc=local"`
- `ldapBindDn <administrator@aaa.local> -ldapBindDnPassword <password> -ldapLoginName sAMAccountName`

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- `add authentication policy aaa-ldap-adv-pol -rule true -action aaa-ldap-act`
- `bind authentication vserver auth_vs -policy <ldap_policy_name> -priority 100 -gotoPriorityExpression NEXT`
- `bind authentication vserver auth_vs -policy <OAuthIDPPolicyName> -priority 5 -gotoPriorityExpression END`
- `bind vpn global –certkey <>`

NOTE

You can bind more than one key. Public parts of certificates bound are sent in response to `jwks\_uri query (https://gw/oauth/idp/certs)`.

NetScaler as an OAuth SP

The authentication, authorization, and auditing traffic management feature supports OAuth authentication for authenticating users to applications that are hosted on applications such as Google, Facebook, and Twitter.

Points to note

- NetScaler Advanced Edition and higher is required for the solution to work.
- OAuth on NetScaler is qualified for all OAuth IdPs that are compliant with "OpenID connect 2.0".

IMPORTANT:

NetScaler might respond with a CSRF error when a content-heavy website sends multiple authentication requests on session expiry. As a workaround, it is recommended that when you configure the OAuth policy, ensure that the policy is configured for both the host name and the path which are the main entry points.

Configure OAuth by using the GUI

1. Configure the OAuth action.
   - Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > OAUTH Actions** and click **Add**.
   - On the **Create Authentication OAuth Server** page, set the following parameter values and click **Create**:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Name: Name for the OAuth Authentication action.
- OAuth Implementation Type: Type of the OAuth implementation. Default value is Generic.
- Client ID: Unique identity of the client/user being authenticated.
- Client Secret: Secret string established by the user and authorization server. MaxLength = 239.
- Authentication: If the authentication is disabled, password is not sent in the request.
- Authorization Endpoint: Authorization endpoint/URL to which the unauthenticated user is redirected. NetScaler redirects the user to this endpoint by adding query parameters including the client ID. If this parameter is not specified then as the default value, NetScaler considers the token Endpoint/URL value.
- Token Endpoint: URL to which the OAuth token is sent to verify its authenticity. Upon successful authentication, the user obtains this token from the authorization server. NetScaler validates the presented token by posting it to the configured URL. Maximum Length: 511. Note: Authorization endpoint or token endpoint are mandatory parameters for OAuth action. Maximum Length: 511.
- ID Token Decrypt Endpoint: URL to which obtained idtoken will be posted to get a decrypted user identity. Encrypted idtoken will be obtained by posting OAuth token to token endpoint. In order to decrypt idtoken, NetScaler posts request to the URL configured Maximum Length: 511. Graph Endpoint: URL of the Graph API service to learn Enterprise Mobility Services (EMS) endpoints. MaxLength = 255
- Cert Endpoint: URL of the endpoint that contains JWKs (Json Web Key) for JWT (Json Web Token) verification. MaxLength = 127
- Audience: Audience for which token sent by Authorization server is applicable. This is typically entity name or url that represents the recipient. MaxLength = 127
- User Name Field: Attribute in the token from which username should be extracted. MaxLength = 127
- User Info URL: URL to which OAuth access token will be posted to obtain user information. MaxLength = 127
- Introspect URL: URL to which access token would be posted for validation. MaxLength = 127
- Skew Time (mins): This option specifies the allowed clock skew in number of minutes that NetScaler allows on an incoming token. For example, if skewTime is 10, then token

© 1997–2026 Citrix Systems, Inc. All rights reserved.

would be valid from (current time - 10) min to (current time + 10) min, ie 20min in all. MaxLength = 127

- Issuer: Identity of the server whose tokens are to be accepted. MaxLength = 127.
- Certificate File Path: Path to the file that contains JWKs (Json Web Key) for JWT (Json Web Token) verification.
- Refresh Interval: Interval at which services are monitored for necessary configuration. Default = 1440
- Default Authentication Group: This is the default group that is chosen when the authentication succeeds in addition to extracted groups.
- Grant Type: Grant type support. value can be code or password
- Attributes: List of attribute names separated by ',' which needs to be extracted.
- Resource URL: Resource URL for Oauth configuration.
- OAuth Misc Flags
  - Base64Encode Authorization With Padding: When sending authorization requests to the token and introspect endpoints, this parameter ensures that the authorization header is Base64 encoded, with padding.
  - Enable JWT Request: Enables the JWT-request parameter to be included in the authorization requests sent to the IdP.
  - Request Attribute: Indicates the Name-Value pairs of attributes to be inserted in the request parameter.

2. Configure the OAuth Policy.

   Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Policy**, and create a policy with OAuth as the action type, and associate the required OAuth action with the policy.

3. Associate the OAuth policy with an authentication virtual server.

   Navigate to **Security > AAA - Application Traffic > Virtual Servers**, and associate the OAuth policy with the authentication virtual server.

NOTE:

Attributes (1 to 16) can be extracted in the OAuth response. Currently these attributes are not evaluated. They are added for the future reference.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure OAuth by using the CLI

1. Define an OAuth action.

```
add authentication OAuthAction <name> [-OAuthType <OAuthType>] [-
authorizationEndpoint <URL>] [-tokenEndpoint <URL>] [-
idtokenDecryptEndpoint <URL>] [-clientID <string>][-clientSecret ]  [-
defaultAuthenticationGroup <string>][-OAuthMiscFlags
(Base64Encode_Authorization_With_Padding | EnableJWTRequest)][-
Attribute1 <string>] [-Attribute2 <string>] [-Attribute3 <string>] [-
Attributes <string>] [-tenantID <string>] [-GraphEndpoint <string>] [-
refreshInterval <positive_integer>] [-CertEndpoint <string>][-audience
<string>] [-userNameField <string>] [-skewTime <mins>] [-issuer
<string>] [-UserInfoURL <URL>] [-CertFilePath <string>] [-grantType
( CODE | PASSWORD )] [-authentication ( ENABLED | DISABLED )] [-
introspectURL <URL>][-allowedAlgorithms <allowedAlgorithms> ...] [-PKCE
( ENABLED | DISABLED )] [-tokenEndpointAuthMethod
<tokenEndpointAuthMethod>] [-metadataUrl <URL>] [-resourceUri <URL>]
```

2. Associate the action with an advanced authentication policy.

```
add authentication Policy <name> -rule <expression> -action <string>
```

Example:

```
add authentication oauthAction a -authorizationEndpoint https://
example.com/ -tokenEndpoint https://example.com/ -clientiD sadf
-clientsecret df
```

For more information on authentication OAuthAction parameters, see authentication OAuthAction.

NOTE:

- When a certEndpoint is specified, NetScaler polls that endpoint at the configured frequency to learn the keys.

To configure a NetScaler to read the local file and parse keys from that file, a new configuration option is introduced as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication OAuthAction <name> -CertFilePath <path to local file
with jwks>
```

OAuth feature now supports the following capabilities in the token API from the Relying Party (RP) side and from the IdP side of NetScaler Gateway and NetScaler.

- PKCE (Proof Key for Code Exchange) support
- Support for client_assertion

Name-value attribute support for OAuth authentication

You can now configure OAuth authentication attributes with a unique name along with the values. The names are configured in the OAuth action parameter either as "Attributes" and the values are obtained by querying for the names. The extracted attributes are stored in the authentication, authorization, and auditing session. Admins can query these attributes either using `http.req.user.attribute("attribute name")` or `http.req.user.attribute(1)`, based on the chosen method of specifying attribute names.

By specifying the name of the attribute, admins can easily search for the attribute value associated with that attribute name. Also, admins no longer have to remember the "attribute1 to attribute16" by its number alone.

IMPORTANT

In an OAuth command, you can configure a maximum of 64 attributes separated by comma with a total size less than 1024 bytes.

Note

The session failure can be avoided if the total value size of "attribute 1 to attribute 16" and the values of attributes specified in "Attributes" are not more than 10 KB.

To configure the name-value attributes by using the CLI

At the command prompt, type:

```
add authentication OAuthAction <name> [-Attributes <string>]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication OAuthAction <name> [-Attributes <string>]
```

Examples:

```
add authentication OAuthAction a1 –attributes "email,company" –attribute1
email

set authentication OAuthAction oAuthAct1 -attributes
"mail,sn,userprincipalName"
```

NetScaler as an OAuth IdP

NetScaler can now be configured as an identity provider by using the OpenID-Connect (OIDC) protocol. OIDC protocol strengthens the identity providing capabilities of NetScaler. You can now access the enterprise wide-hosted application with a single sign-on as OIDC offers more security by not transferring the user password but using tokens with specific lifetime. OpenID is also designed to integrate with non-browser clients such as apps and services. Therefore, the OIDC protocol is widely adopted by many implementations.

NOTE:

- NetScaler must be on version 12.1 or later to work as an OAuth IdP using the OIDC protocol.
- NetScaler as an OAuth IdP only supports RSA-based certificates for authentication.

Advantages of having NetScaler as an OAuth IdP

- Eliminates the overhead of maintaining multiple authentication passwords as the user has a single identity across an organization.
- Provides a robust security for your password as the password is shared only with your identity provider and not with any application you access.
- Provides vast interoperability with various systems, making it easier for the hosted applications to accept OpenID.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE

- NetScaler Advanced Edition or higher is required for using NetScaler as an OAuth IdP.
- Starting from NetScaler release 14.1 build 47.x, the following enhancements are made in the refresh token issued by NetScaler:
  - The default expiry value of the refresh token issued by NetScaler is set to 300 seconds.
  - The access token obtained through the refresh token response includes accurate `iat` (issued at) and `exp` (expiration) values, ensuring successful authentication.

To configure NetScaler as an OAuth IdP using the GUI

1. Create an authentication OAuth IdP policy.
   - Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > OAuth IDP > Policies**.
   - Under **Policies**, click **Add**.
   - On the **Create Authentication OAuth IDP Policy** page, set values for the following parameters and click **Create**.
     - Name: The name of the authentication policy.
     - Action: Name of authentication OAuth IdP profile to apply to requests or connections that match this policy. See step 2 for detailed steps.
     - Log Action: The name of the message log action to use when a request matches this policy. See step 3 for detailed steps. This field is optional.
     - Undefined-Result Action: Action to perform if the result of the policy evaluation is undefined. An undefined event indicates an internal error condition. Available actions are DROP and RESET. This field is optional.
     - Expression: Advanced expression that the policy uses to respond to specific requests. For more information about policies and expressions, see Policies and expressions.
2. Create an authentication OAuth IdP action.
   - On the **Create Authentication OAuth IDP Policy** page, click **Add** in the **Action** field.
   - On the **Create Authentication OAuth IDP Profile** page that appears, set values for the following parameters and click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- Name: Name for the new OAuth IdP single sign-on profile.
- Client ID: Unique identity of the relying party requesting for authentication. The maximum allowed length is 127 characters.
- Client Secret: An unique secret string to authorize the relying party at the authorization server. The maximum allowed length is 239 characters.
- Redirect URL: The relying party URL endpoint to which the OAuth token must be sent. The maximum allowed length is 255 characters.
- Issuer Name: The name to be used in requests sent from NetScaler to the IdP to uniquely identify NetScaler. The maximum allowed length is 127 characters.
- Audience: The target recipient for the token being is sent by the IdP. This is the entity name or the URL that represents the recipient. The maximum allowed length is 127 characters.
- Skew Time: This option specifies the duration for which the token sent by the NetScaler IdP is valid. For example, if the skew time is set to 10 minutes, then the token would be valid from (current time minus 10) minutes to (current time plus 10) minutes; 20 minutes in total. The default duration is 5 minutes.
- Default Authentication Group: Group added to the session's internal group list. This is useful for admins to determine the configuration for the relying party in an nFactor flow. It can be used in the expression `AAA.USER.IS_MEMBER_OF("group name")` for authentication policies to identify the relying party-related nFactor flow. The maximum allowed length is 63 characters.
- Relying Party metadata URL: Endpoint where the NetScaler IdP can get details about the relying party being configured. Metadata response must include endpoints for `jwks_uri` for the relying party public keys. The maximum allowed length is 255 characters.
- Refresh Interval: Intervals at which the relying party metadata is refreshed.
- Signature Service: Select this option to encrypt the token when the NetScaler IdP sends one.
- Attributes: Name-Value pairs of attributes to be inserted in the ID token. Configuration format is `name=value_expr@@@name2=value2_expr@@@`. The `@@@` format is used as a delimiter between the name-value pairs.
- Send Password: Select this option to send the encrypted password in the ID token.

3. Create an audit message action.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- On the **Create Authentication OAuth IDP Policy** page, click **Add** in the **Log Action** field.
- On the **Create Audit Message Action** page, set values for the following parameters and click **Create**.
  - Name: Name of the audit message action.
  - Log Level: Audit log level, which specifies the severity level of the log message being generated.
  - Expression: Default-syntax expression that defines the format and content of the log message.
  - Log in newnslog: Sends the message to the new NSLOG server.

4. Create an authentication OAuth server.
   - Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > OAUTH Actions** and click **Add**.
   - On the **Create Authentication OAuth Server** page, set values for the required parameters and click **Create**.
5. Bind the OAuth IdP policy to the authentication OAuth server.

OAuth feature now supports the following capabilities in the token API from the Relying Party (RP) side and from the IdP side of NetScaler Gateway and NetScaler.

- PKCE (Proof Key for Code Exchange) support
- Support for client_assertion

To configure NetScaler as an IdP using the OIDC protocol by using the CLI

At the command prompt, type the following commands:

```
add authentication OAuthIDPProfile <name> [-clientID <string>] [-
clientSecret ] [-redirectURL <URL>] [-issuer <string>] [-configservice
<string>] [-audience <string>] [-skewTime <mins>] [-
defaultAuthenticationGroup <string>] [-relyingPartyMetadataURL <URL>] [-
refreshInterval <positive_integer>] [-encryptToken ( ON | OFF )] [-
signatureService <string>] [-signatureAlg ( RS256 | RS512 )] [-Attributes
<string>] [-sendPassword ( ON | OFF )]

add authentication OAuthIdPPolicy <name> -rule <expression> [-action
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<string>] [-undefAction <string>] [-comment <string>][-logAction <string>]

add authentication ldapAction aaa-ldap-act -serverIP 10.0.0.10 -ldapBase
"dc=aaa,dc=local"

ldapBindDn <administrator@aaa.local> -ldapBindDnPassword <password>
-ldapLoginName sAMAccountName

add authentication policy aaa-ldap-adv-pol -rule true -action aaa-ldap-act

bind authentication vserver auth_vs -policy <ldap_policy_name> -priority
100 -gotoPriorityExpression NEXT

bind authentication vserver auth_vs -policy <OAuthIDPPolicyName> -priority
5 -gotoPriorityExpression END

bind vpn global –certkey <>
```

Following are the description of parameters used in the preceding commands:

- **OAuthIDPProfile:**
  - **name:** Name for the new OAuth IdP SSO profile.
  - **clientID:** Unique identity of the Relying Party (RP) requesting for authentication. Maximum length: 127.
  - **clientSecret:** Unique secret string to authorize RP at the authorization server. Maximum length: 239.
  - **redirectURL:** Endpoint URL on RP to which the OAuth token is to be sent. Maximum length: 255.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **issuer:** The name to be used in requests sent from NetScaler to IdP to uniquely identify NetScaler. Maximum length: 511.
- **audience:** Audience to which NetScaler IdP must send the token. This parameter is typically the entity name or url that represents the recipient. Maximum length: 127.
- **skewTime:** This option specifies the duration for which the token sent by NetScaler IdP is valid. For example, if `skewTime` is `10`, then token is valid from (current time - 10) min to (current time + 10) min, that is, 20 min in total. Default value: 5.
- **defaultAuthenticationGroup:** This group is a part of the authentication, authorization, and auditing session's internal group list. This parameter is helpful in the nFactor flow to decide the right authentication, authorization, and auditing configuration for the RP. To add the default authentication group in the authentication policy, use the format `AAA.USER.IS_MEMBER_OF("<default_auth_group>")`. Maximum length: 63.
- **relyingPartyMetadataURL:** The endpoint at which NetScaler IdP can get details about RP being configured. Metadata response must include endpoints for `jwks_uri` for RP public keys. Maximum Length: 255.
- **refreshInterval:** Interval at which RP metadata is refreshed. Default value: 50. Minimum value: 0. Maximum Value: 255.
- **encryptToken:** Option to encrypt token when NetScaler IdP sends one. Possible values: `ON`, `OFF`. Default value: `OFF`.
- **signatureService:** Name of the service in cloud that is used to sign the data. This parameter is applicable only if the signature is offloaded to cloud. Maximum Length: 127.
- **signatureAlg:** Algorithm to be used to sign OpenID tokens. Possible values: `RS256`, `RS512`. Default value: `RS256`.
- **Attributes:** Name-Value pairs of attributes to be inserted in the id token. The configuration format for this parameter is `name=value_expr@@@name2=value2_expr@@@`. Value is the advanced policy expression terminated by `@@@` delimiter. The delimiter is not required for the last value. Maximum Length: 2047.
- **sendPassword:** Option to send encrypted password in id token. Possible values: `ON`, `OFF`. Default value: `OFF`.

- **OAuthIdPPolicy:**
  - **name:** Name for the OAuth IdP authentication policy.
  - **rule:** Expression that the policy uses to determine whether to respond to the specified request. This parameter is mandatory. Maximum length: 1499.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **action:** Name of the profile to apply to requests or connections that match this policy. This parameter is mandatory. Maximum length: 127.
- **undefAction:** Action to perform if the result of policy evaluation is undefined (UNDEF). An UNDEF event indicates an internal error condition. Only `DROP` or `RESET` actions can be used. Maximum length: 127.
- **comment:** Any comments to preserve information about this policy. Maximum length: 255.
- **logAction:** Name of message log action to use when a request matches this policy. Maximum length: 127.

NOTES:

- You can bind more than one key. Public parts of certificates bound are sent in response to `jwks\_uri query (https://gw/oauth/idp/certs)`.
- The OAuth IdP introspective endpoint supports the property `active: true`.
- If the authentication virtual server is configured as an OAuth IdP, the well-known OAuth IdP discovery endpoint URL must be `https://<netscaler-oauth-idp-fqdn>/oauth/idp/.well-known/openid-configuration`.
- NetScaler configured as an OAuth IdP does not display the `client_secret_post`, `client_secret_jwt`, `private_key_jwt`, and `client_secret_basic` token endpoint authentication methods in the `.well-known-Endpoint` response sent to the OAuth SP.

Encrypted tokens support on OIDC protocol

NetScaler with the OIDC mechanism now supports the sending of encrypted tokens along with signed tokens. NetScaler uses JSON web encryption specifications to compute the encrypted tokens and supports only compact serialization of encrypted tokens. To encrypt an OpenID token, NetScaler requires the public key of the relying party (RP). The public key is obtained dynamically by polling the relying party's well-known configuration endpoint.

A new "relyingPartyMetadataURL" option is introduced in the "authentication OAuthIDPProfile." profile.

To configure the relying party's endpoint by using CLI

At the command prompt, type:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication OAuthIDPProfile <name> [-relyingPartyMetadataURL <URL>]
[-refreshInterval <mins>] [-status < >]
```

- **relyingPartyMetadataURL** - Endpoint at which NetScaler IdP can get details about the relying party being configured. Metadata response must include endpoints for jwks_uri for RP public keys.
- **refreshInterval** - Defines the rate at which this endpoint must be polled to update the certificates in minutes.
- **status** - Reflects the status of the polling operation. The status is complete once NetScaler successfully obtains the public keys.

Example,

```
set authentication OAuthIDPProfile sample_profile -relyingPartyMetadataURL
https://rp.customer.com/metadata -refreshInterval 50 -status < >
```

After the endpoint is configured, NetScaler first polls the relying party's well-known endpoint to read the configuration. Currently, NetScaler processes only the 'jwks_uri' endpoint.

- If the 'jwks_uri' is absent in the response, the status of the profile is not complete.
- If the 'jwks_uri' is present in the response, NetScaler polls that endpoint also to read the public keys of the relying party.

NOTE:

Only RSAES-OAEP and AES256 GCM encryption type algorithms are supported for token encryption.

Custom attributes support on OpenID Connect

The `OpenID` relying parties might require more than a user name or a user principal name (UPN) in the token to create the user profile or make authorization decisions. Most commonly, the user groups are required to apply authorization policies for the user. Sometimes, more details, such as the first or the last name is required for provisioning a user account.

NetScaler configured as an IdP can be used to send extra attributes in the OIDCid_token using expressions. Advanced policy expressions are used to send the custom attributes as per the

© 1997–2026 Citrix Systems, Inc. All rights reserved.

requirement. The NetScaler OAuth IdP evaluates the expressions corresponding to the attributes and then computes the final token.

NetScaler automatically applies `JSONify` in the output data. For example, numbers (such as SSN) or boolean values (true or false) are not surrounded by quotes. Multi-valued attributes, such as groups are placed within an array marker (""). The complex type attributes are not automatically computed, and you can configure the PI expression of those complex values as per your requirement.

To configure the relying party's endpoint by using CLI

At the command prompt, type:

```
set oauthidpprofile <name> -attributes <AAA-custom-attribute-pattern>
```

The `<AAA-custom-attribute-pattern>` can be described as:

`Attribute1=PI-Expression@@@attribute2=PI-Expression@@@`

'attribute1','attribute2' are literal strings that represent the name of the attribute to be inserted in the ID token.

NOTE:

In the following example, the maximum value of the `"q{myname=http.req.user.name@@@ssn="123456789"@@@jit="false"@@@groups=http.req.user.grou` expression can be 2000 bytes. It contains 4 custom attributes (myname, ssn, jit, groups). The maximum value of each custom attribute is 10000 bytes. For example, the groups attribute (evaluated based on the PI expression `http.req.user.groups`) can contain up to 10000 bytes of data in the OIDCid_token.

Example: `set oauthidpprofile sample_1 -attributes "q{myname=http.req.user.name@@@ssn="123456789"@@@jit="false"@@@groups=http.req.user.groups}`

- The preceding PI expression is an advanced policy expression that represents the value to be used against the attribute. The PI expression can be used to send a string literal, such as '"hardcoded string"'. The string literal is surrounded by double quotes around single quotes or double quotes around a start pattern (the start pattern is `"q()"`). If the value of the attribute is not a string literal, the expression is evaluated at runtime and its value is sent in a token. If the value at runtime is empty, the corresponding attribute is not added to the ID token.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- As defined in the example, "false" is a literal string for the attribute "jit". Also, "`ssn`" has hardcoded value for reference. Groups and "`myname`" are PI expressions that yield strings.

Support for active-active GSLB deployments on NetScaler Gateway

NetScaler Gateway configured as an Identity Provider (IdP) using the OIDC protocol can support active-active GSLB deployments. The active-active GSLB deployment on NetScaler Gateway IdP provides the capability to load balance an incoming user login request across multiple geographic locations.

IMPORTANT

We recommend you to bind CA certificates to the SSL service and enable certificate validation on the SSL service for enhanced security. For more information on configuring a GSLB setup, see Example of a GSLB setup and configuration. **Note:**

Starting from release 14.1 build 73.x, NetScaler supports GSLB information in OAuth access tokens and refresh tokens. This enhancement applies to the OAuth authorization code grant type.

API authentication with the NetScaler appliance

There is a paradigm shift in the way modern applications interact with their clients. Traditionally, browser clients were used to access services. Applications set session cookies to track user context. Modern and distributed applications make it hard to maintain user sessions across microservices. Due to this, most of the application accesses have become API based. Clients that communicate with these distributed services have also evolved. Most clients obtain tokens from a trusted entity called Authorization Server to prove user identity and access. These clients then present the token to the application with each access request. Therefore, traditional proxy devices like NetScaler need to evolve to support these clients. A NetScaler appliance provides a way for administrators to handle such traffic. NetScaler can be deployed as an API Gateway to front-end all the traffic that destined to the published services. An API Gateway can be deployed for traditional (Hybrid Multi Cloud or HMC) or Cloud native environments. The API Gateway terminates all the inbound traffic to offer several services such as authentication, authorization, rate limiting, routing, caching, SSL offload, application firewall, and so on. Therefore, it becomes a critical component in the infrastructure.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Token types

Tokens exchanged during the API access mostly comply with the OAuth or OpenID Connect (OIDC) protocol. Access tokens that are used only for "delegated access" comply with the OAuth protocol, whereas ID Tokens that comply with OIDC carry the user information as well.

Access tokens are normally an opaque or random blob of data. However, they can sometimes be signed tokens that comply with JSON Web Token (JWT) standards. ID Tokens are always signed JWTs.

API Access with OAuth

OAuth authentication type on a NetScaler appliance can be used to handle both OAuth and OIDC protocols. OIDC is an extension to the OAuth protocol.

OAuthAction on a NetScaler appliance can be used to handle interactive clients such as browsers and native clients such as client apps. Interactive clients are redirected to the identity provider for login using the OIDC protocol. Native clients can obtain tokens out of band and can present those tokens at a NetScaler appliance for access.

NOTE:

The access token obtained from endpoints can be cached for subsequent requests, thereby enhancing the API performance.

To configure token caching support by using the command line interface, type the following command at the command prompt:

```
set aaaparameter -APITokenCache <ENABLED>
```

The following sections describe the API access method performed by native clients.

Virtual server for API Access

To deploy a NetScaler appliance for an API access, a Traffic Management (TM) virtual server is deployed with 401 Authentication. It is associated with an authentication (authentication, authorization, and auditing) virtual server to hold the authentication and session policies. Following configuration snippet creates one such virtual server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
Add lb vserver lb-api-access SSL <IP> 443 -authn401 On -AuthnVsName auth-
api-access

Bind ssl vserver lb-api-access -certkeyName <ssl-cert-entity>

Add authentication vserver auth-api-access SSL
```

NOTE:

You would need to bind a service to the traffic management virtual server, and an authentication policy (with OAuthAction described as follows) to the authentication virtual server to complete the configuration.

After creating the virtual server, one needs to add an OAuthAction along with corresponding policy. There are several other options within an OAuth action depending on the token type, and other security mechanisms.

OAuth Configuration for ID Tokens

ID Tokens are always signed JWTs. That is, they carry header, payload and signature. Since these are self-contained tokens, a NetScaler appliance can validate these tokens locally. To validate these tokens, the appliance would need to know the public key of the corresponding private key used to sign these tokens.

Following is an example of OAuthAction with certain mandatory arguments along with "certEndpoint".

```
Add authentication OAuthAction oauth-api-access -clientid <your-client-id>
-clientsecret <your-client-secret> -authorizationEndpoint <URL to which
users would be redirected for login> -tokenEndpoint <endpoint at which
tokens could be obtained> -certEndpoint <URL at which public keys of IdP
are published>
```

Where,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Client ID** – Unique string that identifies SP. Authorization server infers client configuration using this ID. Maximum Length: 127.
- **Client Secret** – Secret string established by user and authorization server. Maximum Length: 239.
- **authorizationEndpoint** - URL at which users would normally log in (when using interactive clients).
- **tokenEndpoint** - URL on Authorization Server at which tokens/code are obtained/exchanged
- **certEndpoint** - URL at which Authorization Server publishes public keys used to sign the tokens. Authorization Server can publish more than one key and choose one of them to sign tokens.

> **NOTE:**
>
> Client ID/Client Secret/authorizationEndpoint/TokenEndpoint are optional parameters for API Access. However, it is a good practice to provide values for these parameters as the action entity can be reused for different purposes.

In the preceding configuration ‘certEndpointpoint’ is essential for ID Token validation. This endpoint contains public keys of the certificate used to sign the tokens. These public keys must correspond to JWKs (JSON Web Keys) specification.

Once the certEndpoint is configured at the NetScaler appliance, it polls the endpoint periodically (with the default interval of 1 day that can be customizable in the configuration) to keep the public keys up to date. After the public keys are available, ADC can perform local validation of the incoming ID Tokens.

OAuth Configuration for opaque access tokens

Opaque tokens cannot be verified locally on the NetScaler appliance. These need to be validated on the Authorization server. A NetScaler appliance uses ‘introspection protocol’ mentioned in the OAuth specifications to verify these tokens. A new option, introspectURL, is provided in the OAuth configuration for verifying opaque tokens.

```
set oauthAction oauth-api-acccess -introspectURL <URL of the Authorization
Server for introspection>
```

The format of the introspection API conforms to the specification at `https://tools.ietf.org/html/rfc7662#section-2.1` as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
POST /introspect HTTP/1.1

Host: server.example.com

Accept: application/json

Content-Type: application/x-www-form-urlencoded

Authorization: Basic czZCaGRSa3F0MzpnWDFmQmF0M2JW

token=mF_9.B5f-4.1JqM&token_type_hint=access_token
```

Binding policy to Authentication virtual server

Once OAuthAction is created, a corresponding policy needs to be created for invoking it.

```
add authentication policy oauth-api-access -rule <> -action <oauth-api-
access>

bind authentication vserver auth-api-access -policy oauth-api-access -pri
100
```

Additional security settings on a NetScaler appliance

Token validation includes token lifetime checks. Tokens outside of acceptable time are rejected. Following are the additional settings for extra security. Some of these are recommended to be configured always.

Audience: OAuth Action can be configured with an intended recipient of the token. All tokens are matched against this configured URL. A NetScaler appliance has an additional capability where the audience field actually points to a pattern set on the appliance. Using this pattern set, an administrator can configure more than one URL for the audience.

```
add policy patset oauth_audiences

bind patset oauth_audiences https://app1.company.com
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind patset oauth_audiences https://app2.company.com

bind patset oauth_audiences httpsL//app1.company.com/path1

set oAuthAction oauth-api-access -audience oauth_audiences
```

In the preceding example, more than one audience is specified in a pattern set. Therefore, an incoming token is allowed only if it contains any of the configured URLs in the pattern set.

Issuer: Identity of the server whose tokens are to be accepted. Maximum Length: 127. It is a good practice to configure the issuer of the tokens in OAuth action. This ensures that tokens issued by the wrong authorization server are not allowed.

SkewTime: Specifies the allowed clock skew in number of minutes that a NetScaler appliance allows on an incoming token. For example, if skewTime is 10, then the token would be valid from (current time - 10) min to (current time + 10) min, that is 20 min in all. Default value: 5

AllowedAlgorithms: This option allows administrator to restrict certain algorithms in the incoming tokens. By default, all the supported methods are allowed. However, these can be controlled using this option.

The following configuration ensures only tokens that use RS256 and RS512 are allowed:

```
set oAuthAction oauth-api-access -allowedAlgorithms RS256 RS512
```

After the preceding configuration is performed, only tokens that use RS256 and RS512 are allowed.

Bypassing certain traffic from authentication

In many instances, there are some discovery APIs that are publicly accessible to the clients. These APIs typically reveal configuration and capabilities of the service itself. AN administrator can configure the NetScaler appliance to bypass authentication from these metadata URLs using ‘No Authentication’ policy described as follows:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication policy auth-bypass-policy -rule <> -action NO_AUTHN

bind authentication vserver auth-api-access -policy auth-bypass-policy
-pri 110
```

NO_AUTHN is an implicit action that results in authentication to be completed when the rule matches. There are other uses of NO_AUTHN action beyond the scope of API access.

LDAP authentication

You can use Lightweight Directory Access Protocol (LDAP) to authenticate users against Active Directory or other LDAP directories.

As with other types of authentication policies, a Lightweight Directory Access Protocol (LDAP) authentication policy comprises an expression and an action. After creating an authentication policy, bind it to an Authentication Virtual Server with a priority. Then add that Virtual Server to an Authentication Profile.

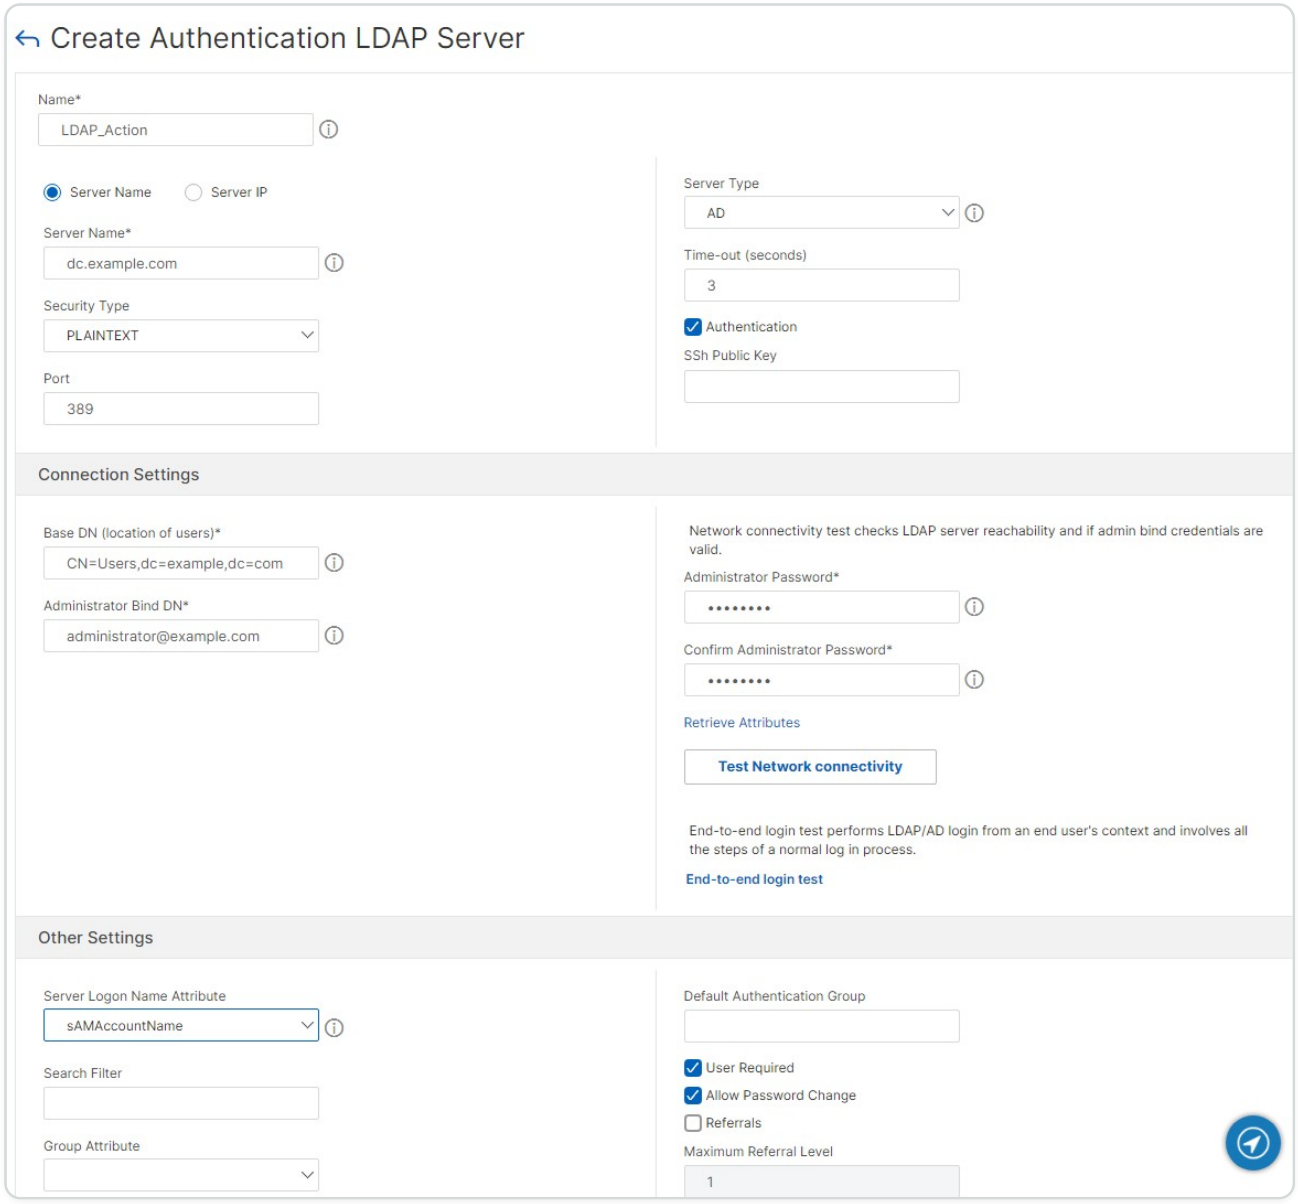
NOTE:

Basic LDAP policies are deprecated may not work when used from a VPN Virtual Server. Instead, follow the instructions below to create an advanced policy, along with an Authentication Virtual Server and Authentication Profile. Then add the Authentication Profile to the VPN virtual server.

Create an LDAP Authentication Action using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > LDAP**.
2. Click **Add**. The **Create Authentication LDAP Server** screen is displayed.
3. Enter a name.
4. Update the parameter details. For more details, see LDAP parameters.
5. Click **Test network connectivity** to verify the entered details. See also Testing LDAP authentication.
6. Click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Create an LDAP Authentication Action using the CLI

Use the command `add authentication ldapAction`. For more information, see add authentication ldapAction.

Example:

```
add authentication ldapAction ldap_server -serverip 1.1.1.1 -ldapBase
"Cn=Users,dc=example,dc=com" -ldapBindDn admin@example.com
-ldapBindDnPassword -ldapLoginName sAMAccountName
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Edit an LDAP authentication action using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > LDAP**.
2. Click the action you wish to edit.
3. Update the parameters. For more details, see LDAP parameters.
4. Click **Test network connectivity** to verify the entered details. See also Testing LDAP authentication.
5. Click **OK** to save.

Edit an LDAP authentication action using the CLI

Use the command `set authentication ldapAction`. For more information, see set authentication ldapAction.

Example:

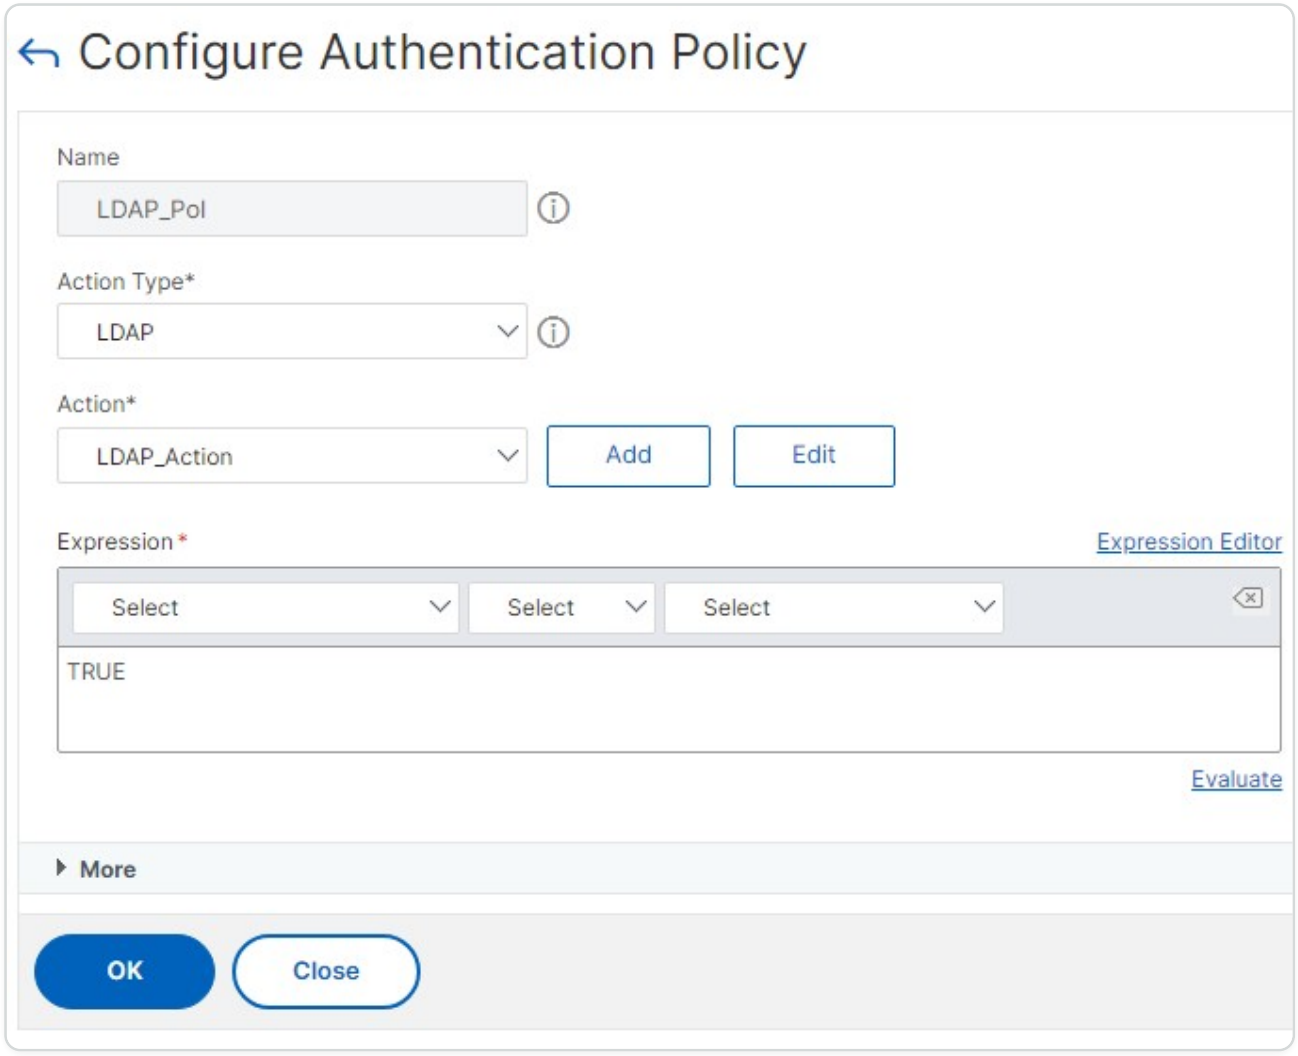
```
set authentication ldapAction ldap_server -serverip 2.2.2.2
```

Create an LDAP authentication policy using the GUI

Once you have created your LDAP action, create an Authentication Policies:

1. Navigate to **Security > AAA - Application Traffic > Advanced Policies > Policy**.
2. Click **Add**.
3. Enter a **Name**.
4. Choose **Action Type** of **LDAP**.
5. Under **Action** specify the authentication server you created.
6. Enter the **Expression** as **TRUE**.
7. Click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Kv

Create an LDAP authentication policy using the CLI

Use the command `add authentication ldappolicy`. For more information, see add authentication ldappolicy.

Example:

```
add authentication Policy LDAP_Pol -rule TRUE -action ldap_server
```

LDAP parameters

Server name or Server IP

Normally you configure the NetScaler to use the IP address of the authentication server during authentication. With LDAP authentication servers, you can also configure the ADC to use the FQDN of the LDAP server instead of its IP address to authenticate users. Using an FQDN can

© 1997–2026 Citrix Systems, Inc. All rights reserved.

simplify an otherwise much more complex authentication, authorization, and auditing configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication action. When creating the action, you use the **serverName** parameter instead of the **serverIP** parameter, and substitute the server's FQDN for its IP address.

Before you decide whether to configure the ADC to use the IP or the FQDN of your LDAP server to authenticate users, consider that configuring authentication, authorization, and auditing to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

Instead of adding a single server, you can set up a load balancer in front of multiple LDAP servers and add this load balancer to the LDAP action. For example in Active Directory domain you could create a load balancer in front of multiple domain controllers.

Security type

Choose whether to use plain text, SSL or TLS.

It is recommended that you configure your LDAP servers for TLS to ensure that all data is encrypted.

Port

The typical port numbers for LDAP connections are:

- 389 for unsecured LDAP connections (for plain text LDAP)
- 636 for secure LDAP connections (for SSL LDAP)
- 3268 for Microsoft unsecure LDAP connections (for plain text Global Catalog Server)
- 3269 for Microsoft secure LDAP connections (for SSL Global Catalog Server)

Authenticate

Enable authentication to validate users' passwords. If you disable authentication then the user's password is not validated.

From the GUI, tick **Authentication**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

From the CLI, use parameter `authentication`.

Server Logon Name Attribute

Choose which LDAP field contain the username.

The following table contains examples of user attribute fields for common LDAP servers:

LDAP SERVER	USER ATTRIBUTE	CASE SENSITIVE
Microsoft Active Directory Server	userPrincipalName or sAMAccountName	No
Novell eDirectory	ou	Yes
IBM Directory Server	uid	Yes
Lotus Domino	CN	Yes
Sun ONE directory (formerly iPlanet)	uid or cn	Yes

Server type

If you are using Active Directory (AD) or Novell Directory Services (NDS) then choose the appropriate type.

Base DN

The Base DN specifics the section of directory in which the server will search for users.

This table contains examples of the base DN:

LDAP SERVER TYPE	EXAMPLE
Microsoft Active Directory Server	CN=Users,dc=example,dc=com
Novell eDirectory	ou=users,ou=dev
IBM Directory Server	cn=users
Lotus Domino	OU=City,O=`Citrix`, C=US
Sun ONE directory (formerly iPlanet)	ou=People,dc=`citrix`,dc=com

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Bind DN

The Bind DN specifies the user that is used to query the LDAP directory and validate the credentials.

The following table contains examples of bind DN:

LDAP SERVER	BIND DN
Microsoft Active Directory Server	CN=Administrator, CN=Users, DC=`citrix`, DC=local
Novell eDirectory	cn=admin, o=`citrix`
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=`Citrix`, C=US
Sun ONE directory (formerly iPlanet)	uid=admin,ou=Administrators, ou=TopologyManagement,o=NetscapeRoot

For more information about setting up authentication policies in general, see Authentication Policies. For more information about NetScaler expressions, which are used in the policy rule, see Policies and Expressions.

Administrator password

Enter the **Administrator Password** corresponding to the Bind DN. Enter it again in the **Confirm Administrator Password** field.

Referral

In addition to standard authentication functions, LDAP can search other active directory (AD) servers for user accounts for users that do not exist locally. This function is called referral support or referral chasing.

LDAP referral support is disabled by default and cannot be enabled globally. It must be explicitly enabled for each LDAP action. Make sure that the AD server accepts the same `binddn` `credentials` that are used with the referring (GC) server. To enable referral support, you configure an LDAP action to follow referrals, and specify the maximum number of referrals to follow.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

If referral support is enabled, and the NetScaler receives an LDAP_REFERRAL response to a request, authentication, authorization, and auditing follows the referral to the active directory (AD) server contained in the referral and performs the update on that server. First, authentication, authorization, and auditing looks up the referral server in DNS, and connects to that server. If the referral policy requires SSL/TLS, it connects via SSL/TLS. It then binds to the new server with the `binddn credentials` that it used with the previous server, and performs the operation which generated the referral. This feature is transparent to the user.

To enable LDAP referral support type the following commands:

```
set authentication ldapAction <name> -followReferrals ON

set authentication ldapAction <name> -maxLDAPReferrals <integer>
```

Key-based authentication

With key-based authentication, you can fetch the list of public keys that are stored on the user object in the LDAP server through SSH. The NetScaler appliance during the role-based authentication (RBA) process must extract public SSH keys from the LDAP server. The retrieved public key, which is compatible with SSH, must allow you to log in through the RBA method. This has the following benefits:

- Can store the retrieved public key, and the LDAP action uses this attribute to retrieve SSH key information from the LDAP server.
- Can extract attribute names of up to 24 KB.

Note

> The external authentication server, such as LDAP is used only to retrieve SSH key information. It is not used for the authentication purpose.

Following is an example of the flow of events through SSH:

- SSH daemon sends an AAA_AUTHENTICATE request with password field empty to authentication, authorization, and auditing daemon port.
- If LDAP is configured to store the SSH public key, authentication, authorization, and auditing responds with the "sshPublicKey" attribute along with other attributes.
- SSH daemon verifies these keys with the client keys.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- SSH daemon passes the user name in the request payload, and authentication, authorization, and auditing returns the keys specific to this user along with generic keys.

In the GUI you can enter the **SSh Public Key**.

From the CLI, you can configure key based authentication by using the `sshPublicKey` parameter. For example:

```
set authentication ldapAction LDAP_Action -sshPublicKey <sshPublicKey>
```

Name-value attributes

You can configure the attributes of LDAP authentication with a unique name along with values. The names are configured in the LDAP action parameter and the values are obtained by querying for the name. This feature has the following benefits:

- Minimizes the effort for administrators by remembering the attribute by name (not just by value)
- Enhances the search to query the attribute value associated with a name
- Provides an option to extract multiple attributes

From the GUI, click **More** and in the **Attributes** field enter a comma separated list of attributes to fetch from the LDAP server.

From the CLI, use the `attributes` parameter.

For example:

```
set authentication ldapAction ldapAct1 -attributes "company, mail"
```

Cloud attributes settings

When you enable the Cloud Attributes parameter, NetScaler extracts (from the LDAP Active Directory) the attributes required for Citrix Cloud operations. For more information about the prerequisites for the cloud attributes, see Connect an on-premises Citrix Gateway as an identity provider to Citrix Cloud.

From the GUI, set **Cloud Attributes** to **Enabled** or **Disabled**.

From the CLI, use the parameter `CloudAttributes`

For example:

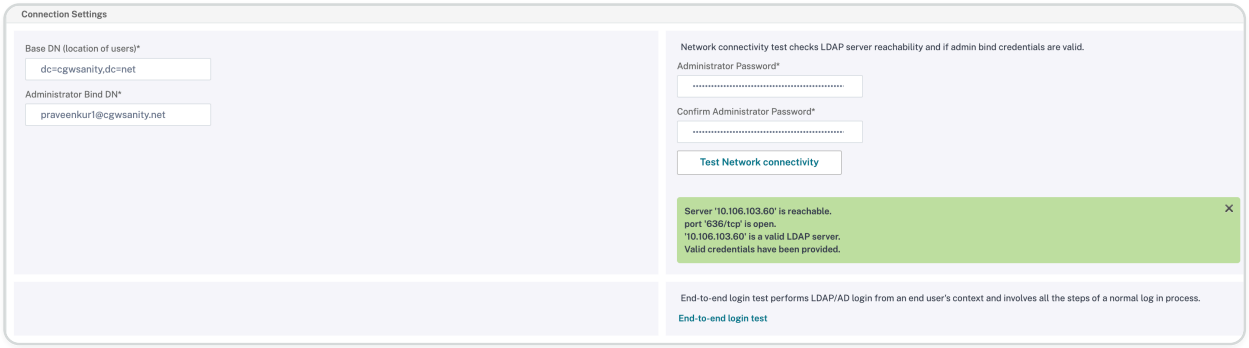
© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication ldapAction LDAP_Action  -CloudAttributes ENABLED
```

Testing LDAP authentication

The NetScaler appliance can validate end-to-end LDAP authentication through the GUI. This helps you check you've correctly configured the LDAP action and troubleshoot issues.

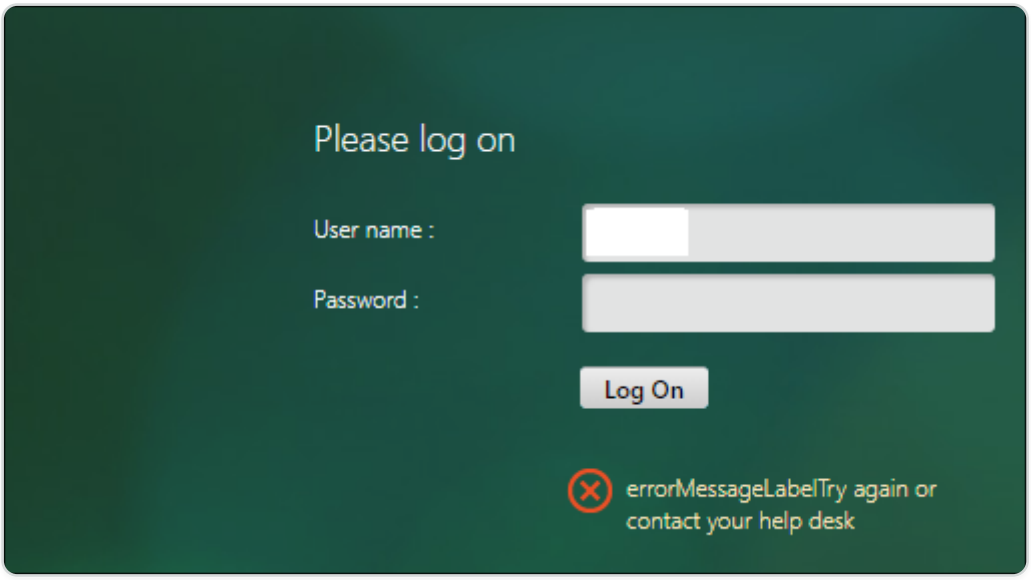
1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > LDAP**.
2. Select the available **LDAP action** from the list.
3. On the **Configure Authentication LDAP Server** page, scroll down to the **Connections Settings** section.
4. Click **Test Network connectivity** to check the LDAP server connection. You can view a pop-up message of successful connection to the LDAP server with TCP port details and authenticity of valid credentials.



5. To view the end-to-end LDAP authentication, click **End-to-end login test** link.
6. In the **End-to-end login test** page, click **Test**.
   - On the authentication page, enter the valid credentials to log in. The success screen is displayed.

   - If the authentication fails, the error screen is displayed.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



You can also reach the **Configure Authentication LDAP Server** screen by navigating to **Authentication > Dashboard**

Password expiry notification for LDAP authentication

The NetScaler appliance supports password expiry notification for LDAP based authentication. By using this feature, administrators can notify the end users about the password expiry threshold time in days.

NOTE

Expiry notification can be configured for clientless VPN and Full VPN use cases and not for ICA® Proxy.

Advantages of password expiry notification

- Permit users to reset their passwords on their own and provide administrators a flexible way to notify the end user about their password expiry in days.
- Eliminates end user dependence to track their password expiration days.
- Sends notifications to the VPN portal page to the users (based on the number of days) to change their password before expiry.

NOTE

This feature is applicable only for LDAP based authentication schemes, not for RADIUS or TACACS.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Understanding the password expiry notification

The NetScaler appliance fetches two attributes (`Max-Pwd-Age and Pwd-Last-Set`) from the LDAP authentication server.

- **Max-Pwd-Age.** This attribute denotes the maximum amount of time, in 100-nanosecond intervals, until the password is valid. The value is stored as a large integer that represents the number of 100-nanosecond intervals from the time the password was set before the password expires.
- **Pwd-Last-Set.** This attribute determines the date and time at which the password for an account was last changed.

By fetching the two attributes from the LDAP authentication server, the NetScaler appliance determines the time left for the password to expire for a particular user. This information is collected when any user credentials are validated on the authentication server and a notification is sent back to the user.

Use the parameter `pwdExpiryNotification` in the `set aaa parameter` command. By using this parameter, an administrator can keep track the number of days left for password expiry. The NetScaler appliance can now start notifying the end user about their password expiry.

NOTE

Currently, this feature works only for authentication servers having Microsoft AD servers with LDAP implementation. Support for OpenLDAP based servers is not currently availabile.

Following is an example of the flow of events for setting a password expiry notification:

1. An administrator, by using the NetScaler appliance, sets a time (e.g. 14-days) for password expiration.
2. The user sends an HTTP or HTTPS request to access a resource on the back-end server.
3. Before providing access, the NetScaler appliance validates the user credentials with what is configured on the LDAP authentication server.
4. Along with this query to the authentication server, the NetScaler appliance carries the request to fetch the details of the two attributes (`Max-Pwd-Age and Pwd-Last-Set`).
5. Based on the time left for the password to expire, an expiry notification is displayed.
6. The user then takes appropriate action to update the password.

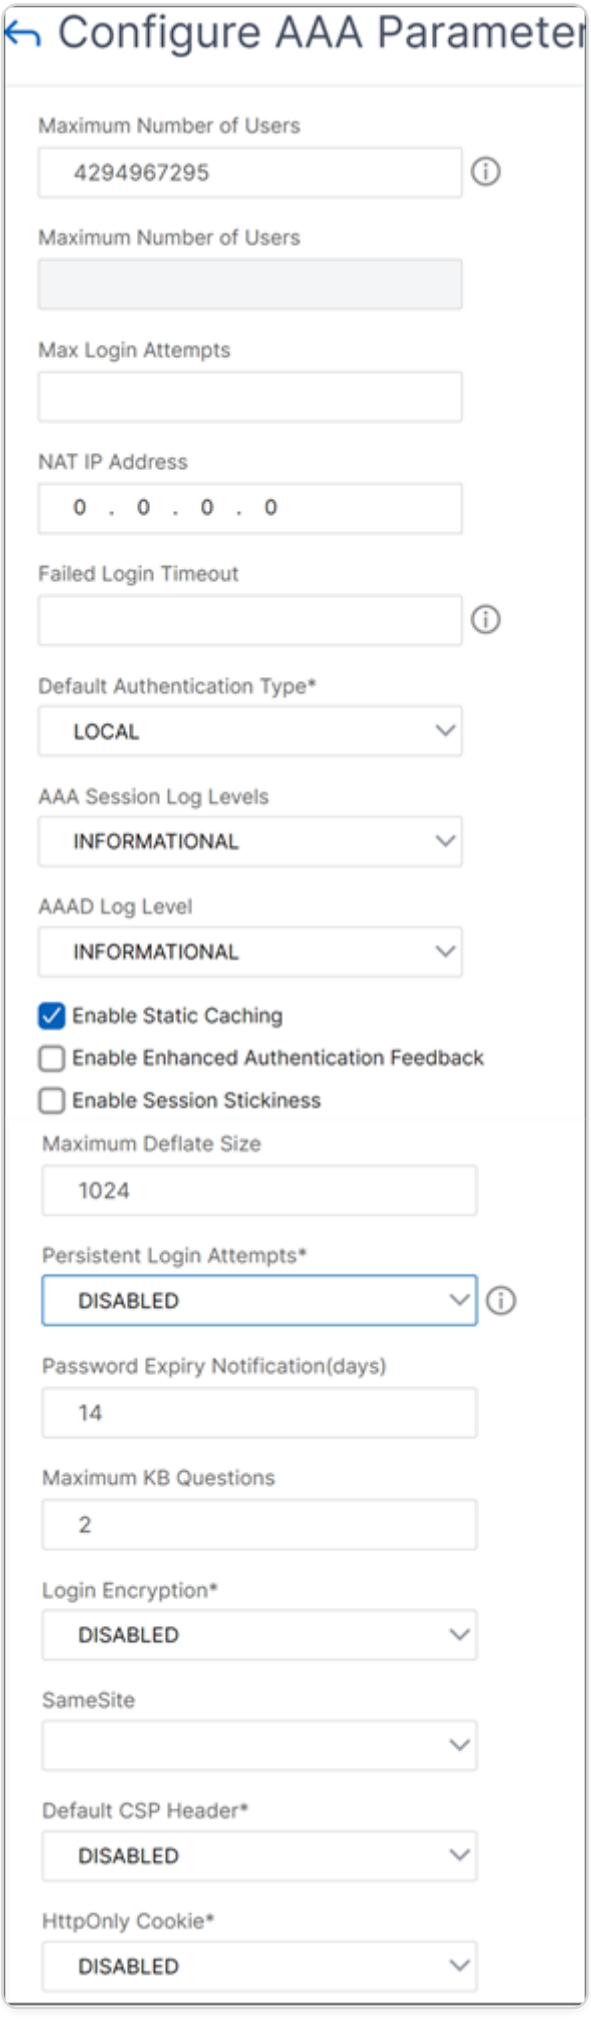
© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure password expiry notification

To configure expiry notification by using GUI:

1. Navigate to **Security > AAA - Application Traffic > Authentication Settings**.
2. Click **Change authentication AAA settings**.
3. On the **Configure AAA Parameter** page, specify the days in the **Password Expiry Notification(days)** field. The maximum value is 255 days.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Click **OK.**

To configure password expiry using the CLI use command:

```
set aaa parameter –pwdExpiryNotificationDays <positive_integer>

show aaa parameter
```

The maximum value is 255 days.

For example:

```
> set aaa parameter -pwdExpiryNotificationDays 14

Done

> show aaa parameter                          Configured AAA parameters
 EnableStaticPageCaching: YES  EnableEnhancedAuthFeedback: NO
 DefaultAuthType: LOCAL MaxAAAUsers:           Unlimited
                    AAAD nat ip: None            EnableSessionStickiness :
NO  aaaSessionLoglevel : INFORMATIONAL               AAAD Log Level :
INFORMATIONAL                 Dynamic address: OFF

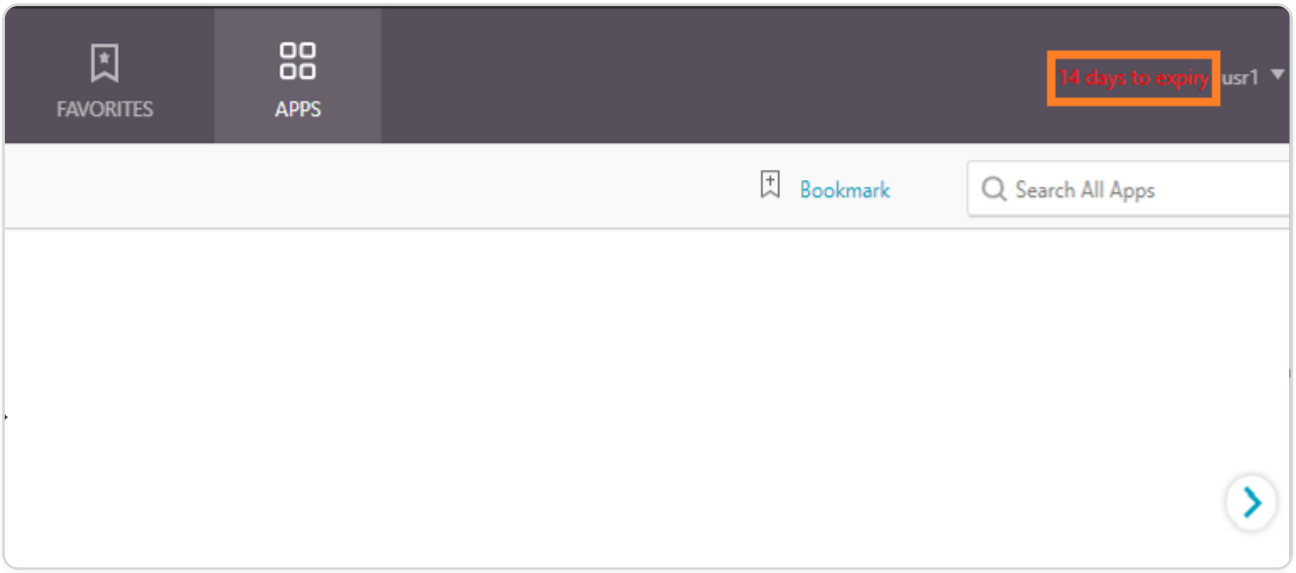
    GUI mode: ON

    Max Saml Deflate Size: 1024             Password Expiry Notification
Days: 14
```

Display of notifications

When a user logs in whose password is about to expire, a notification appears on the top right corner of the VPN portal page.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



LDAP authentication with nested group extraction

Nested group extraction is the process of retrieving not only the groups that a user is directly a member of but also the child groups of those groups.

For example, the User1 object within the Active Directory is a direct member of 3 group objects: ADC-GROUP1, LOCAL-GROUP1, and DOMAIN-GROUP1. These 3 group objects are also members of other group objects, creating a nested group structure:

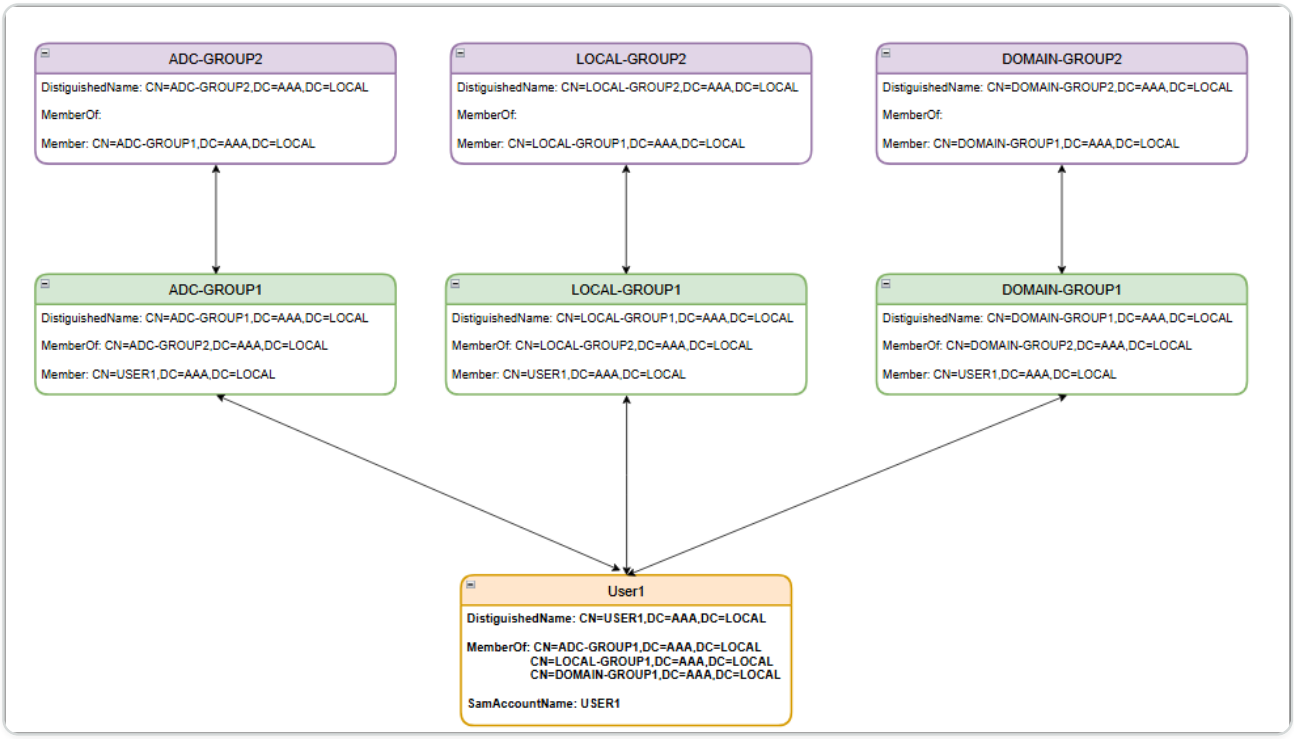
- ADC-GROUP1 is a member of ADC-GROUP2.
- LOCAL-GROUP1 is a member of LOCAL-GROUP2.
- DOMAIN-GROUP1 is a member of DOMAIN-GROUP2.

A user object's `memberOf` attribute lists its groups, while a group's `member` attribute lists its members. For the preceding example:

- User1 object's `memberOf` attribute references ADC-GROUP1.
- ADC-GROUP1 object's `member` attribute references User1.

This bidirectional relationship allows for the extraction of both direct and nested group memberships. The following diagram illustrates the Active Directory objects and their attributes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



To configure LDAP authentication with nested group extraction using the CLI

At the command prompt, type:

```
add authentication ldapAction <name> {-serverIP <ip_addr|ipv6_addr|*> | {-
serverName <string>}} [-serverPort <port>] [-authTimeout
<positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] {-
ldapBindDnPassword } [-ldapLoginName <string>] [-searchFilter <string>] [-
groupAttrName <string>] [-subAttributeName <string>] [-secType <PLAINTEXT
| TLS | SSL>] [-svrType ( AD | NDS )][-ssoNameAttribute <string>] [-
authentication ( ENABLED | DISABLED )] [-requireUser ( YES | NO )] [-
passwdChange ( ENABLED | DISABLED )] [-nestedGroupExtraction ( ON | OFF )
[-maxNestingLevel <positive_integer>]  [-groupSearchSubAttribute <string>]
 [-groupSearchFilter <string>]] [-followReferrals ( ON | OFF )  [-
maxLDAPReferrals <positive_integer>]][-referralDNSLookup <A-REC | SRV-REC
| MSSRV-REC>  [-msSRVRecordlocation <string>]] [-validateServerCert ( YES
| NO )] [-ldapHostname <string>] [-groupNameIdentifier <string>][-
groupSearchAttribute <string>] [-defaultAuthenticationGroup <string>] [-
Attribute1 <string>] [-Attribute2 <string>] [-Attribute3 <string>] [-
Attribute4 <string>] [-Attribute5 <string>][-Attribute6 <string>] [-
Attribute7 <string>] [-Attribute8 <string>] [-Attribute9 <string>] [-
Attribute10 <string>] [-Attribute11 <string>] [-Attribute12 <string>] [-
Attribute13 <string>][-Attribute14 <string>] [-Attribute15 <string>] [-
Attribute16 <string>] [-Attributes <string>] [-sshPublicKey <string>] [-
pushService <string>] [-OTPSecret <string>] [-email <string>][-KBAttribute
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
<string>] [-alternateEmailAttr <string>] [-CloudAttributes ( ENABLED |
DISABLED )]
```

Following are the mandatory parameters in the preceding command:

- **serverIP:** IP address assigned to the LDAP server.
- **serverName:** LDAP server name as an FQDN, which is mutually exclusive with LDAP IP address. Maximum length: 127.
- **serverPort:** Port on which the LDAP server accepts connections. Default value: `389`. Minimum value: `1`.
- **ldapBase:** Base (node) from which to start LDAP searches. If the LDAP server is running locally, the default value of base is `dc=netscaler, dc=com`. Maximum length: 127.
- **ldapBindDn:** Full distinguished name (DN) that is used to bind to the LDAP server. Default: `cn=Manager,dc=netscaler,dc=com`. Maximum length: 127.
- **ldapLoginName:** LDAP login name attribute. NetScaler uses the LDAP login name to query external LDAP servers or Active Directories. Maximum length: 127.
- **searchFilter:** String to be combined with the default LDAP user search string to form the search value. For example, if the search filter `"vpnallowed=true"` is combined with the LDAP login name `"samaccount"` and the user-supplied user name is "bob", the result is the LDAP search string `""&(vpnallowed=true)(samaccount=bob)""`. Maximum length: 255.

  NOTE:

  Enclose the search string in two sets of double quotation marks.

The following parameters are required to configure the `GroupSearch`:

- **groupAttrName:** LDAP group attribute name. This parameter is used for group extraction on the LDAP server. Maximum length: 31.

  NOTE:

  If the `groupSearchFilter` parameter is included in the command, then do not use this parameter. In other scenarios, use the `groupAttrName` parameter for group search operation.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **subAttributeName:** LDAP group sub-attribute name. This parameter is applied on group attribute value, which is extracted from `groupAttrName` parameter. Maximum length: 31.
- **nestedGroupExtraction:** Allow nested group extraction, in which NetScaler queries external LDAP servers to determine whether a group is part of another group. Possible values: `ON`, `OFF`. Default value: `OFF`.
- **maxNestingLevel:** If nested group extraction is `ON`, this parameter specifies the number of levels up to which group extraction is performed. Default value: `2`. Minimum value: `2`. Maximum Value: `255`.
- **groupSearchSubAttribute:** LDAP group search subattribute that is used to determine to which groups a specific group belongs. This parameter is applied on group attribute value when the nested group extraction process happens. Maximum length: 31.
- **groupSearchFilter:** String to be combined with the default LDAP group search string to form the search value. For example, the group search filter `""vpnallowed=true""` when combined with the group identifier `""samaccount""` and the group name `""g1""` yields the LDAP search string `""(&(vpnallowed=true)(samaccount=g1)""`. If `nestedGroupExtraction` is `ENABLED`, the filter is applied on the first level group search as well, otherwise first level groups (which user is a direct member of) are fetched without applying this filter. Maximum length: 127.

  NOTE:

  Enclose the search string in two sets of double quotation marks.

- **groupNameIdentifier:** Name that uniquely identifies a group in LDAP or Active Directory. Maximum length: 127.
- **groupSearchAttribute:** LDAP group search attribute used to determine the groups to which a specific group belongs. Maximum length: 31.

Different use cases for search filter

Based on the LDAP configuration, NetScaler generates the search filter and attribute list, sends the query to the LDAP server, and retrieves the user information. This process ensures that NetScaler can efficiently locate and retrieve user objects and their attributes for authentication and authorization purposes.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Use case 1: Basic user search

Example 1:

User input: user1

LDAP configuration: `-ldapLoginName samAccountName`

Here, the `samAccountName` attribute corresponds to the user input `user1`.

Generated search filter: `(&(samAccountName=user1)(objectClass=*))`

Example 2:

User input: user1@aaa.local

LDAP configuration: `add authentication ldapAction <name> -ldapLoginName userPrincipalName`

Here, the `userPrincipalName` attribute corresponds to the user input `user1@aaa.local`.

Generated search filter: `(&(userPrincipalName=user1@aaa.local)(objectClass=*))`

Use case 2: User search with additional filter

User input: user1

To limit the user search to objects with the `vpnallowed` attribute set to `true`, use the following LDAP configuration.

```
add authentication ldapAction <name> -ldapLoginName samAccountName -searchFilter "(vpnallowed=true)"
```

Here, the `samAccountName` attribute corresponds to the user input `user1`.

Generated search filter: `(&(samAccountName=user1)(vpnallowed=true))`

Use case 3: User search with group extraction

User input: user1

Use the following LDAP configuration to retrieve groups directly associated with the user object.

```
add authentication ldapAction <name> -ldapLoginName samAccountName -groupAttrName memberOf
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Here, the `samAccountName` attribute corresponds to the user input `user1`.

Generated search filter: `(&(samAccountName=user1)(objectClass=*))`

Attributes associated with user object: `memberOf`

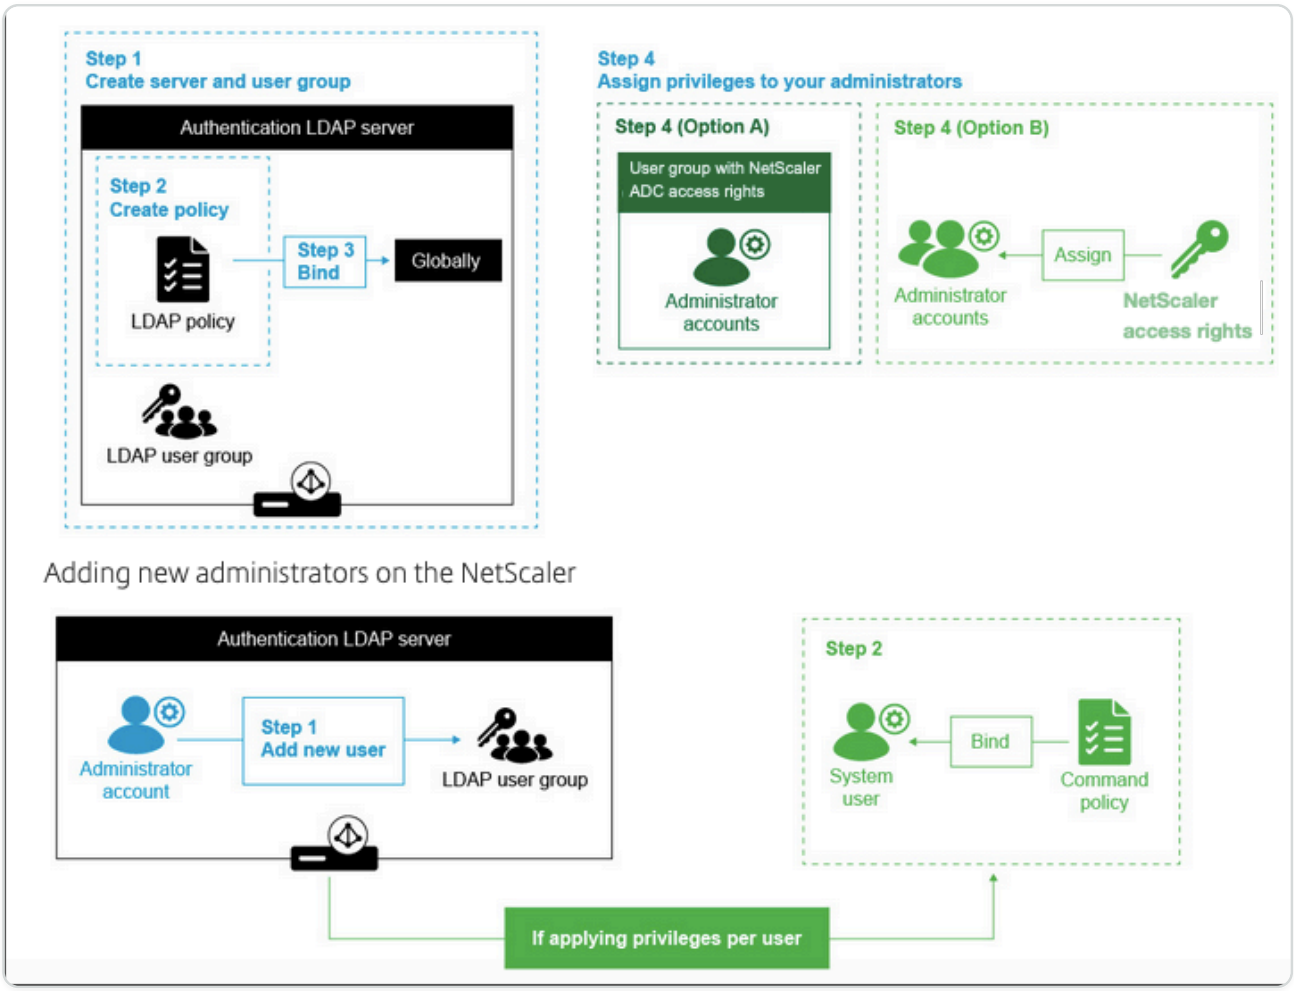
Configure LDAP authentication on NetScaler for management purposes

You can configure user logon to NetScaler using the Active Directory credentials (user name and password) for management purposes (superuser, read-only, network privileges and all others).

Prerequisites

- Windows Active Directory domain controller servers
- A dedicated domain group for NetScaler® administrators
- NetScaler Gateway 10.1 and later versions

The following figures illustrate the LDAP authentication on NetScaler.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

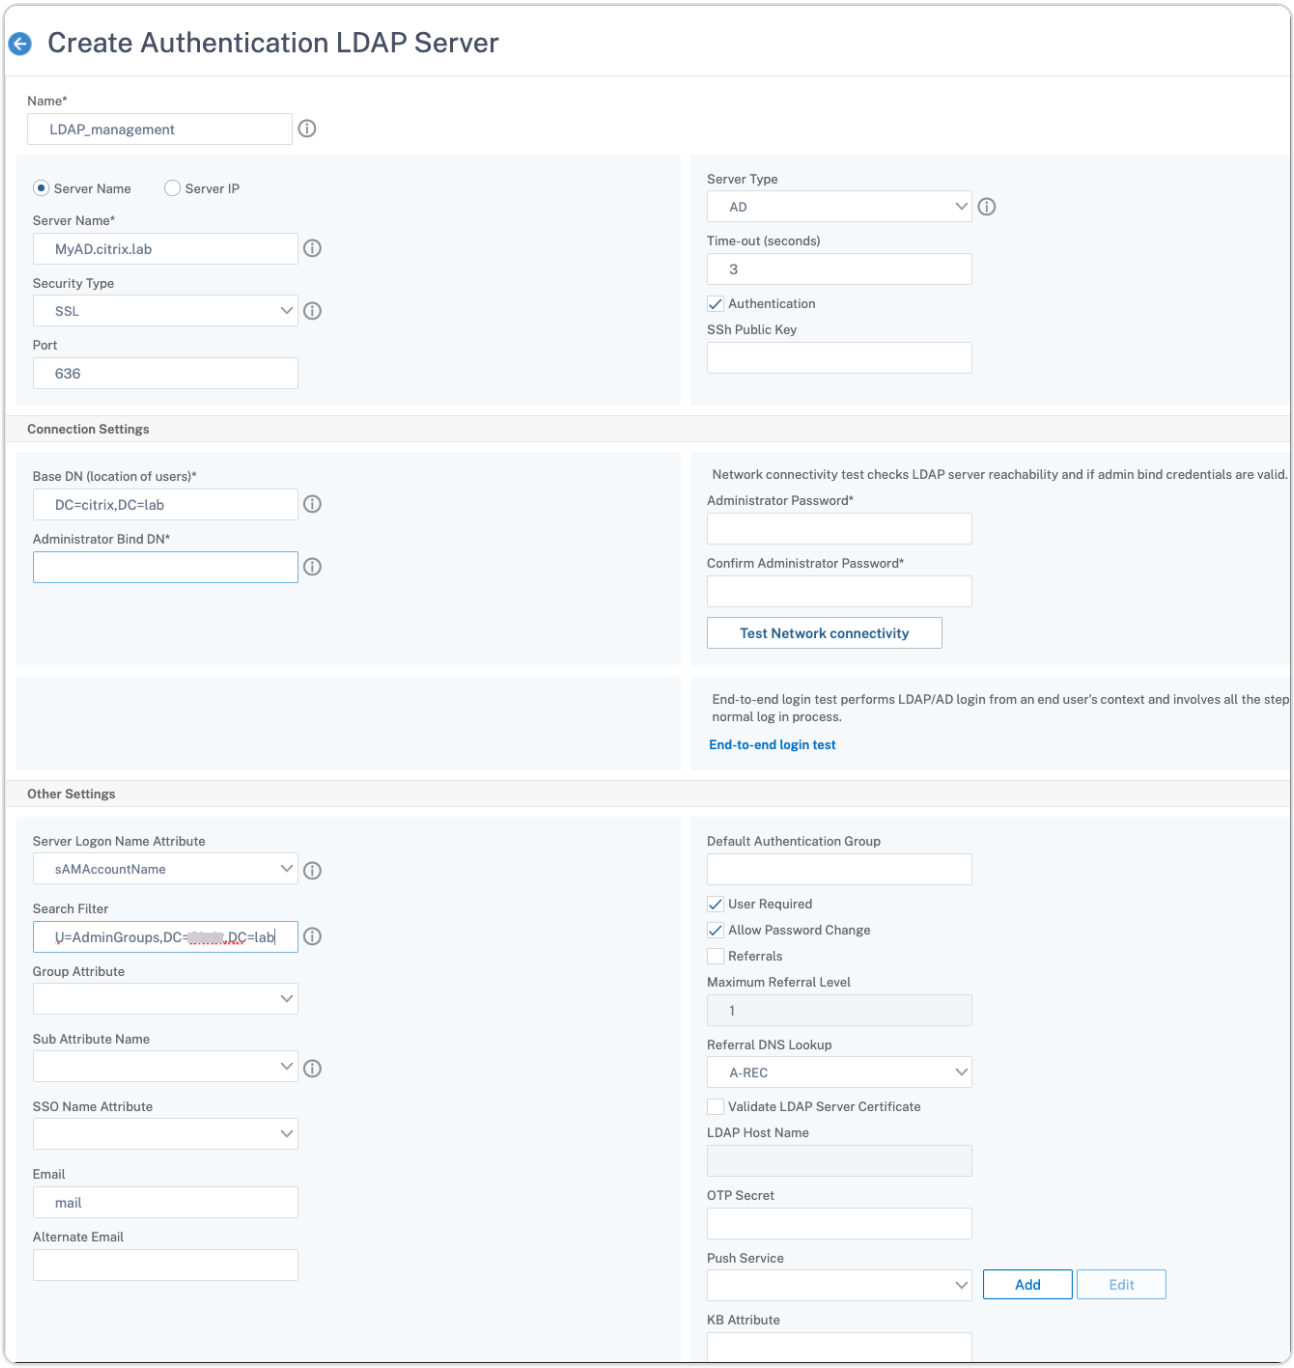
High level configuration steps

1. Create an LDAP server.
2. Create an LDAP policy.
3. Bind the LDAP policy.
4. Assign privileges to your administrators by one of the following ways:
    - Apply privileges on a group.
    - Apply privileges individually for each user.

Create an authentication LDAP server

1. Navigate to **System > Authentication > Basic Policies > LDAP**.
2. Click the **Servers** tab and then click **Add**.
3. Complete the configuration, and then click **Create**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



NOTE:

In this example, access to NetScaler is restricted by using a Search Filter to authenticate based on user group membership. The value used for this example is - &(memberof=CN=NSG_Admin,OU=AdminGroups,DC=Citrix,DC=lab)

Create an LDAP Policy

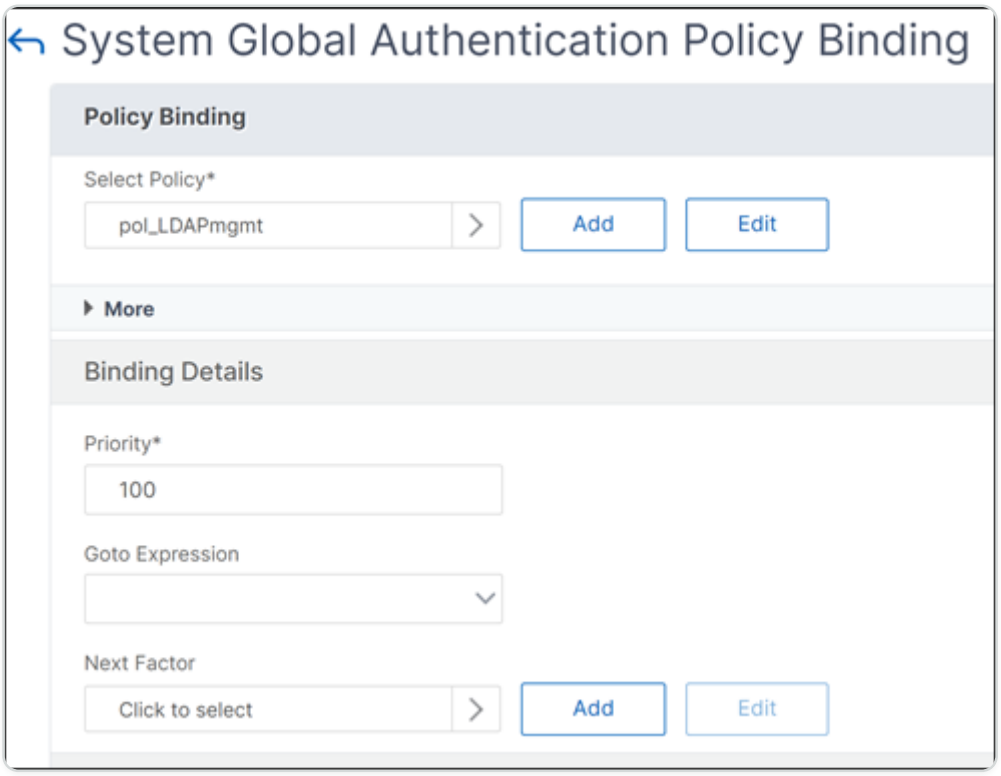
1. Navigate to **System > Authentication > Advanced Policies > Policy**.
2. Click **Add**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

3. Enter a name for the policy and select the server that you created in the previous steps.
4. In the **Expression** text field, enter the appropriate expression, and then click **Create**.

Bind the LDAP policy globally

1. Navigate to **System > Authentication > Advanced Policies > Policy**.
2. In the **Authentication Policies** page, click **Global Bindings**.
3. Select the policy that you created (in this example, pol_LDAPmgmt).
4. Choose a priority accordingly (the lower the number, the higher the priority).
5. Click **Bind** and then **Done**. A green checkmark appears in the **Globally Bound** column.



Assign privileges to your administrators

You can choose one of the following two options.

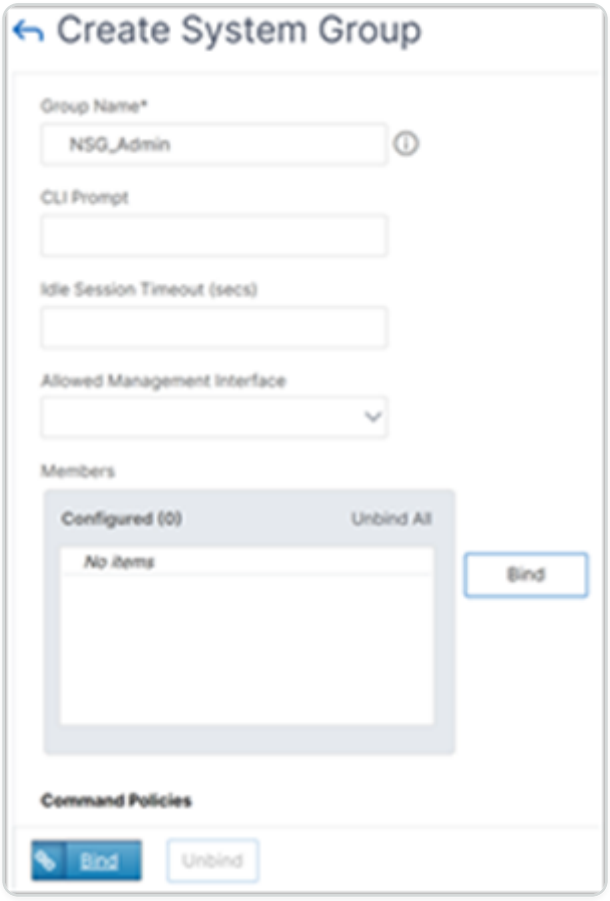
- **Apply privileges on a group:** Add a group in NetScaler and assign the same access rights for each user who is a member of this group.
- **Apply privileges individually for each user:** Create each user administrator account and assign rights for each of them.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Apply privileges on a group

When you apply privileges to a group, users in the Active Directory group specified in the Search Filter (for example, NSG_Admin) can access the NetScaler Management interface. These users receive a superuser command policy.

1. Navigate to **System > User Administration > Groups**.
2. Click **Add**, enter the details as per the requirement, and then click **Create**.



You have defined the Active Directory group for the users and the command policy level for their account during login. You can add new administrator users to the LDAP group you configured on the search filter.

NOTE:

The group name must match the Active Directory record.

Apply privileges individually for each user

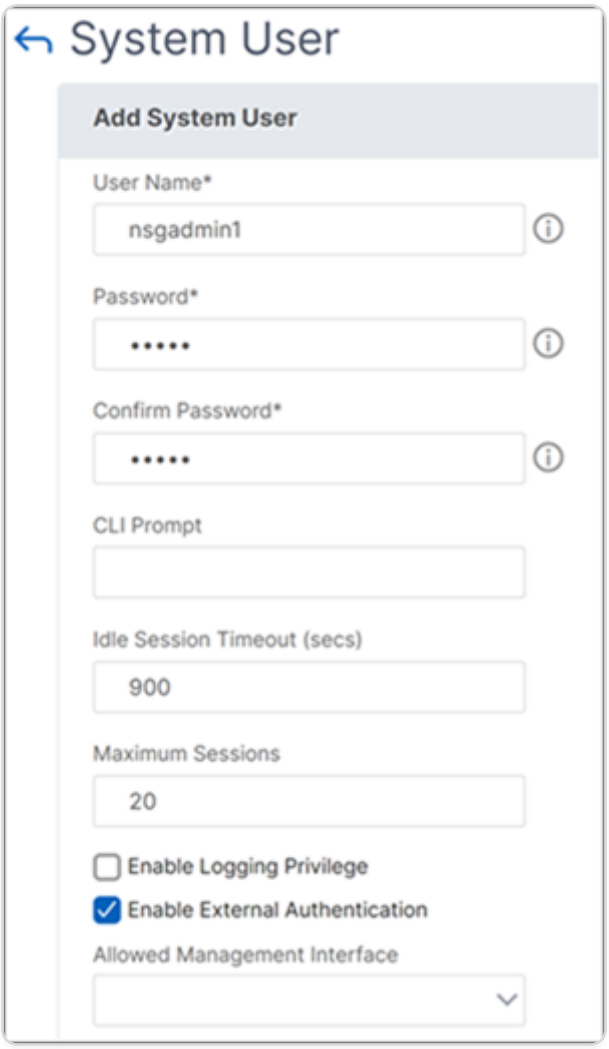
In this scenario, users who are member of your Active Directory group configured in the search filter (in this example, NSG_Admin) can connect to the NetScaler management interface but do not

© 1997–2026 Citrix Systems, Inc. All rights reserved.

have any privileges until you create the specific user on NetScaler and bind the command policy to it.

1. Navigate to **System > User Administration > Users**.
2. Click **Add**.
3. Enter the details as per the requirement.

   Note: Make sure to select **Enable External Authentication**.



4. Click **Continue**.

You have defined the Active Directory user and the command policy level that must be associated to the account when logging in.

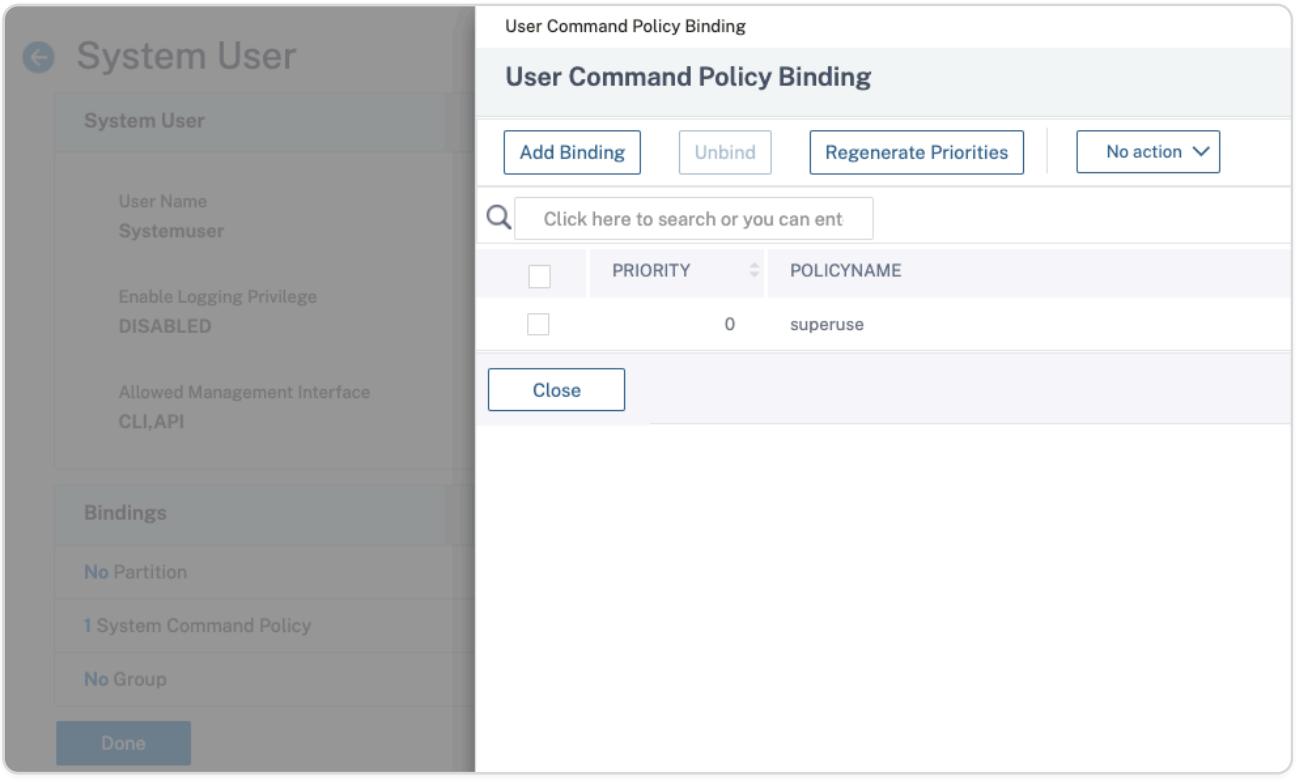
© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The user name must match the existing user's Active Directory record.
- When you add a user to the NetScaler for external authentication, you must provide a password, if the external authentication is not available. For the external authentication to work properly, the internal password must not be the same as the user account LDAP password.

Add command policy to the user

1. Navigate to **System > User Administration > Users**.
2. Select the user that you created, and then click **Edit.**
3. In **Bindings**, click **System Command Policy**.
4. Select the correct command policy to apply to your user.
5. Click **Bind** and then click **Close**.



To add more administrators;

- Add the administrator users to the LDAP group you configured on the search filter.
- Create the system user in NetScaler and assign the correct command policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

To configure LDAP authentication on NetScaler for management purposes by using the CLI

Use the following commands as a reference to configure logon for a group with superuser privileges on NetScaler CLI.

1. Create an LDAP server.

```
add authentication ldapAction LDAP_mgmt -serverIP myAD.citrix.lab
-serverPort 636 -ldapBase "DC=citrix,DC=lab" -ldapBindDn
readonly@citrix.lab -ldapBindDnPassword -ldapLoginName sAMAccountName
-searchFilter
"&(memberof=CN=NSG_Admin,OU=AdminGroups,DC=citrix,DC=lab)"
-groupAttrName memberOf
```

2. Create an LDAP policy.

   We recommend that you use advanced authentication policies instead of classic policies, as classic policies are deprecated.

   Advanced authentication policy:

```
add authentication policy pol_LDAPmgmt -rule true -action LDAP_mgmt
```

   Classic authentication policy:

```
add authentication ldapPolicy pol_LDAPmgmt ns_true LDAP_mgmt
```

3. Bind the LDAP policy.

```
bind system global pol_LDAPmgmt -priority 110
```

4. Assign privileges to your administrators.

   - To apply privileges on the group, use the following command:

```
add system group NSG_Admin

bind system group NSG_Admin -policyName superuser 100
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- To apply privileges individually for each user, use the following command:

```
add system user admyoa

bind system user admyoa superuser 100
```

Configure LDAP after offloading SSL to a load balancing virtual server

In a NetScaler appliance, the AAAD process is used for performing basic authentication like LDAP, RADIUS, TACACS for management access or authentication authorization and gateway access. As AAAD runs on the management CPU, there might be issues with intermittent authentication failures. To avoid these failures, the load balancing virtual server can be used to offload the SSL functionality from AAAD.

Advantages of offloading SSL to a load balancing virtual server

- Enhanced AAAD performance. In AAAD, for every authentication request for the LDAP server of SSL type, a new SSL session is established. As the AAAD process runs on the management CPU, establishing the SSL session impacts performance during high requests to the AAAD. Offloading SSL functionality to load balancing virtual server enhances the performance of the AAAD process.
- Render client certificate to server. The client LDAP library in AAAD only performs server certificate validation, there is no support for rendering client certificate to server. Because SSL mutual authentication requires rendering the client certificate for establishing the SSL connection, offloading SSL functionality to the load balancing virtual server enables rendering of the client certificate to the server.

Configure LDAP after offloading SSL to the load balancing virtual server

Note: After you create a load balancing virtual server IP address for LDAP and point the LDAP request server to the virtual server IP address, the traffic is sourced from the SNIP.

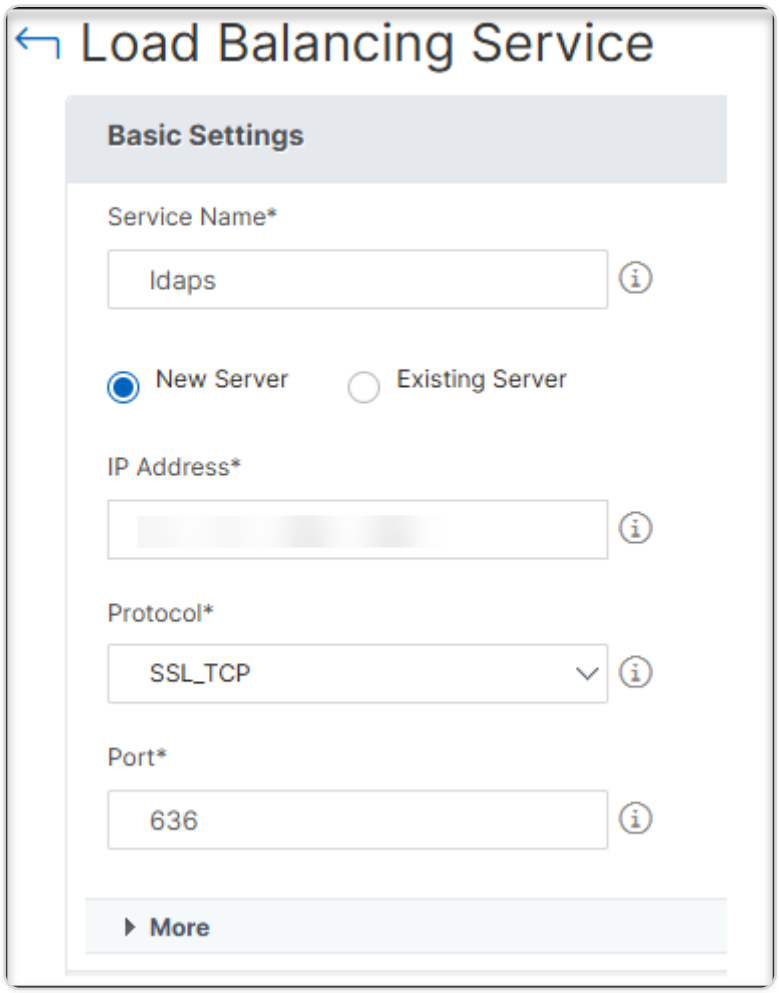
Prerequisites

- Ensure that secure LDAP is enabled on the domain controllers, which the NetScaler appliance uses for authentication. By default, with an enterprise CA, all the domain controllers enroll for a certificate using the domain controller certificate template.
- Ensure that secure LDAP is working by using the ldp.exe and connecting to the domain controller over port 636 and SSL.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

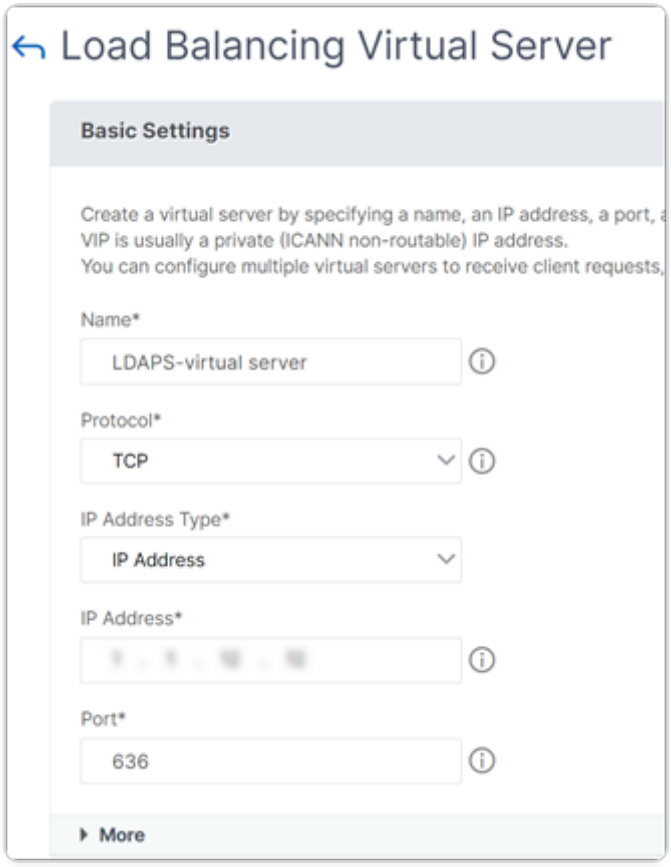
Configure LDAP after offloading SSL to the load balancing virtual server by using the GUI

1. Create a load balancing service with the protocol set to SSL_TCP.
   - Navigate to **Traffic management > Load Balancing > Services** and click **Add**.
   - Specify the IP address of the domain controller and set the port number to 636.
   - Click **OK**.



2. Create a load balancing virtual server for LDAPS load balancing service.
   a. Navigate to **Traffic Management > Load Balancing >Virtual Servers**.
   b. Set the protocol to TCP, enter the IP address, set the port to 636, and click **OK**.

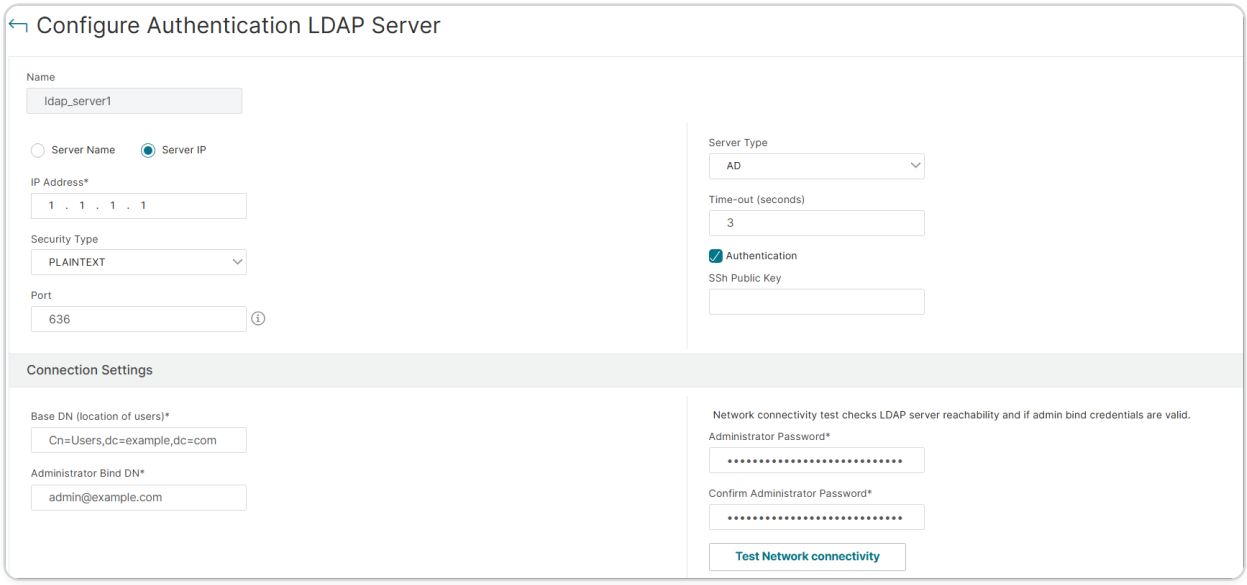
© 1997–2026 Citrix Systems, Inc. All rights reserved.



3. Bind the LDAPS service to the load balancing virtual server.
    - Navigate to **Traffic Management > Load Balancing > Virtual Servers**.
    - Select the LDAP virtual server. The **Load Balancing Virtual Server** page appears.
    - In the **Services and Service Groups** section, click **No Load Balancing Virtual Server Service Binding**. The **Service Binding** page appears.
    - Select the load balancing service. Update the other required fields and click **Bind**.
    - Click **Done**.
4. Now change the LDAP authentication policy server to point to the load balancing virtual server for secure LDAP. The security type must be PLAINTEXT.
    a. Navigate to **NetScaler Gateway > Polices > Authentication > LDAP**.
    b. On the **Servers** tab, select the LDAP server and click **Edit**.
    c. Change the IP address to the LDAPS VIP hosted on the NetScaler appliance created earlier.
    d. Change **Security Type** to **PLAINTEXT**, change **Port** to 636, select the **Allow Password Change** checkbox, if necessary (SLDAP allows password changes).
    e. Click **Test Network Connectivity** to verify connectivity.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

f. Click **OK**.



You can check the authentication dashboard to confirm that the status of the LDAP server is UP. Also, check the authentication logs to confirm that the authentication is working as intended.

Configure LDAP after offloading SSL to the load balancing virtual server by using the CLI

1. Configure an LDAP server for the AAAD process. The following sample configuration establishes the SSL connection with a load balancing virtual server without SSL mutual authentication.

```
add authentication ldapAction ldap_act -serverIP 1.1.12.12 -serverPort
389 -secTYPE PLAINTEXT -ldapBase "dc=aaatm-test,dc=com" -ldapBindDn
administrator@aaatm-test.com -ldapBindDnPassword <password>
-ldapLoginName samAccountName
```

2. Configure a load balancing virtual server for the LDAP virtual server. The load balancing virtual server is of type TCP.

```
add lb vserver lb_vs_ldaps TCP 1.1.12.12 389 -persistenceType NONE
-cltTimeout 9000
```

3. Configure a service for the load balancing virtual server. The service type is SSL-TCP.

```
add service svc_ldaps 1.1.10.1 SSL_TCP 636
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Configure a CA certificate for the service and set the "serverAuth" parameter for the server certificate validation.

```
bind ssl service ldaps -certkeyName ca-cert -CA

set ssl service ldaps -serverAuth enabled
```

5. Attach the certificate to the service that is rendered to the LDAP server.

```
bind ssl service ldaps -certkeyName usr_cert [client-certificate for
client-authentication]
```

6. Bind the service to the load balancing virtual server.

```
bind lb vserver lb_vs_ldaps svc_ldaps
```

NOTE:

- Use port 389 for **PLAINTEXT** traffic between AAAD and the load balancing virtual server.
- Use port 636 (SSL_TCP) for secure communication to the domain controller.

RADIUS authentication

As with other types of authentication policies, a Remote Authentication Dial In User Service (RADIUS) authentication policy includes an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy. However, setting up a RADIUS authentication policy has certain special requirements that are described below.

Normally you configure the NetScaler to use the IP address of the authentication server during authentication. With RADIUS authentication servers, you can now configure the ADC to use the FQDN of the RADIUS server instead of its IP address to authenticate users. Using an FQDN can simplify an otherwise much more complex authentication, authorization, and auditing configuration in environments where the authentication server might be at any of several IP addresses, but always uses a single FQDN. To configure authentication by using a server's FQDN instead of its IP address, you follow the normal configuration process except when creating the authentication

© 1997–2026 Citrix Systems, Inc. All rights reserved.

action. When creating the action, you substitute the **serverName** parameter for the **serverIP** parameter.

Before you decide whether to configure the NetScaler to use the IP or the FQDN of your RADIUS server to authenticate users, consider that configuring authentication, authorization, and auditing to authenticate to an FQDN instead of an IP address adds an extra step to the authentication process. Each time the ADC authenticates a user, it must resolve the FQDN. If a great many users attempt to authenticate simultaneously, the resulting DNS lookups might slow the authentication process.

NOTE

- These instructions assume that you are already familiar with the RADIUS protocol and have already configured your chosen RADIUS authentication server.
- Starting from release 14.1 build 43.x, NetScaler includes the message authenticator attribute in RADIUS access requests by default as part of the RADIUS user authentication process. The message authenticator attribute is not applicable to RADIUS accounting requests.

To add an authentication action for a RADIUS server by using the command-line interface

If you authenticate to a RADIUS server, you need to add an explicit authentication action. To add an authentication action at the command prompt, type the following command:

```
add authentication radiusAction <name> [-serverip <IP> | -serverName]
<FQDN>][-serverPort <port>] [-authTimeout <positive_integer>] {-radKey }
[-radNASip ( ENABLED | DISABLED )][-radNASid <string>] [-radVendorID
<positive_integer>][-radAttributeType <positive_integer>][-radGroupsPrefix
<string>] [-radGroupSeparator <string>][-passEncoding <passEncoding>][-
ipVendorID <positive_integer>] [-ipAttributeType <positive_integer>][-
accounting ( ON | OFF )][-pwdVendorID <positive_integer> [-
pwdAttributeType <positive_integer>]] [-defaultAuthenticationGroup
<string>] [-callingstationid ( ENABLED | DISABLED )]
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

The following example adds a RADIUS authentication action named **Authn-Act-1**, with the server IP **10.218.24.65**, the server port **1812**, the authentication timeout **15** minutes, the RADIUS key **WareTheLorax**, NAS IP disabled, and NAS ID **NAS1**.

```
add authentication radiusaction Authn-Act-1 -serverip 10.218.24.65
-serverport 1812 -authtimeout 15 -radkey WareTheLorax -radNASip DISABLED
-radNASid NAS1

Done
```

The following example adds the same RADIUS authentication action, but using the server FQDN **rad01.example.com** instead of the IP.

```
add authentication radiusaction Authn-Act-1 -serverName rad01.example.com
-serverport 1812 -authtimeout 15 -radkey WareTheLorax -radNASip DISABLED
-radNASid NAS1

Done
```

NOTE:

Starting from release 14.1 build 47.x, you can disable the inclusion of the message authenticator attribute in RADIUS access requests using the following command:

```
add authentication radiusAction &lt;name> -messageAuthenticator OFF
```

To include the message authenticator attribute in RADIUS access requests, set the `-messageAuthenticator` attribute to `ON`.

To configure an authentication action for an external RADIUS server by using the command line

To configure an existing RADIUS action, at the command prompt, type the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication radiusAction <name> [-serverip <IP> | -serverName]
<FQDN>][-serverPort <port>] [-authTimeout <positive_integer>] {-radKey }
[-radNASip ( ENABLED | DISABLED )][-radNASid <string>] [-radVendorID
<positive_integer>][-radAttributeType <positive_integer>][-radGroupsPrefix
<string>] [-radGroupSeparator <string>][-passEncoding <passEncoding>][-
ipVendorID <positive_integer>] [-ipAttributeType <positive_integer>][-
accounting ( ON | OFF )][-pwdVendorID <positive_integer> [-
pwdAttributeType <positive_integer>]] [-defaultAuthenticationGroup
<string>] [-callingstationid ( ENABLED | DISABLED )]
```

To remove an authentication action for an external RADIUS server by using the command-line interface

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
```

Example

```
rm authentication radiusaction Authn-Act-1

Done
```

To configure a RADIUS server by using the configuration utility

NOTE

In the configuration utility, the term server is used instead of action, but refers to the same task.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Radius**
2. In the details pane, on the **Servers** tab, do one of the following:
   - To create a RADIUS server, click **Add**.
   - To modify an existing RADIUS server, select the server, and then click **Edit**.
3. In the **Create Authentication RADIUS Server** or **Configure Authentication RADIUS Server** dialog, type or select values for the parameters. To fill out parameters that appear beneath **Send Calling Station ID**, expand **Details**.
   - Name*—radiusActionName (Cannot be changed for a previously configured action)
   - Authentication Type*—authtype (Set to RADIUS, cannot be changed)
   - Server Name / IP Address*—Choose either Server Name or Server IP
     - Server Name*—serverName \<FQDN\>
     - IP Address*—serverIp \<IP\> If the server is assigned an IPv6 IP address, select the IPv6 checkbox.
   - Port*—serverPort
   - Time-out (seconds)*—authTimeout
   - Secret Key*—radKey (RADIUS shared secret.)
   - Confirm Secret Key*—Type the RADIUS shared secret a second time. (No command line equivalent.)
   - Send Calling Station ID—callingstationid
   - Group Vendor Identifier—radVendorID
   - Group Attribute Type—radAttributeType
   - IP Address Vendor Identifier—ipVendorID
   - pwdVendorID—pwdVendorID
   - Password Encoding—passEncoding
   - Default Authentication Group—defaultAuthenticationGroup
   - NAS ID—radNASid
   - Enable NAS IP address extraction—radNASip
   - Group Prefix—radGroupsPrefix
   - Group Separator—radGroupSeparator

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- IP Address Attribute Type—ipAttributeType
- Password Attribute Type—pwdAttributeType
- Accounting—accounting

4. Click **Create** or **OK**. The policy that you created appears in the Servers page.

Support to pass through RADIUS attribute 66 (Tunnel-Client-Endpoint)

NetScaler now allows the pass-through of RADIUS attribute 66 (Tunnel-Client-Endpoint) during RADIUS authentication. By applying this feature, the clients IP address is received by second-factor authentication from entrusting to make risk-based authentication decisions.

A new attribute "tunnelEndpointClientIP" is introduced in both "add authentication radiusAction" and "set radiusParams" command.

To use this feature, at NetScaler command prompt, type:

```
add authentication radiusAction <name> {-serverIP <ip_addr|ipv6_addr|*> |
{-serverName <string>}} [-serverPort <port>] … [-tunnelEndpointClientIP
(ENABLED|DISABLED)]

set radiusParams {-serverIP <ip_addr|ipv6_addr|*> |{-serverName <string>}}
[-serverPort<port>] … [-tunnelEndpointClientIP(ENABLED|DISABLED)]
```

Example

```
add authentication radiusAction radius -severIP 1.217.22.20 -serverName
FQDN -serverPort 1812 -tunnelEndpointClientIp ENABLED

set radiusParams -serverIp 1.217.22.20 -serverName FQDN1 -serverPort 1812
-tunnelEndpointClientIP ENABLED
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Support for validating end-to-end RADIUS authentication

NetScaler can now validate end-to-end RADIUS authentication through a GUI. To validate this feature, a new "test" button is introduced in the GUI. NetScaler administrator can use this feature to achieve the following benefits:

- Consolidates the complete flow (packet engine – aaa daemon – external server) to provide better analysis
- Reduces time on validating and troubleshooting issues related to individual scenarios

You have two options to configure and view the test results of RADIUS end-to-end authentication by using the GUI.

From system option

1. Navigate to **System > Authentication > Basic Policies > RADIUS,** click **Servers** tab.
2. Select the available **RADIUS action** from the list.
3. On the **Configure Authentication RADIUS Server** page, you have two options under **Connections Settings** section.
4. To check the RADIUS server connection, click the **Test RADIUS Reachability** tab.
5. To view the end-to-end RADIUS authentication, click the **Test End User Connection** link.

From Authentication option

1. Navigate to **Authentication > Dashboard**, select the available RADIUS action from the list.
2. On the **Configure Authentication RADIUS Server** page, you have two options under **Connections Settings** section.
3. To check the RADIUS server connection, click the **Test RADIUS Reachability** tab.
4. To view the end-to-end RADIUS authentication status, click the **Test End User Connection** link.

RADIUS authentication using TCP or TLS

Starting from release 13.1–27.59, RADIUS authentication is supported on TCP and TLS protocols as well.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- The **Test RADIUS Reachability** option is not supported for RADIUS on TCP and TLS transport types.
- RADIUS authentication using UDP is not supported on FIPS appliances.

Configure RADIUS over TCP by using the CLI

At the command prompt type:

```
add authentication radiusAction <name> [-serverIP] [-serverPort ] [-
transport <transport>]
```

Example:

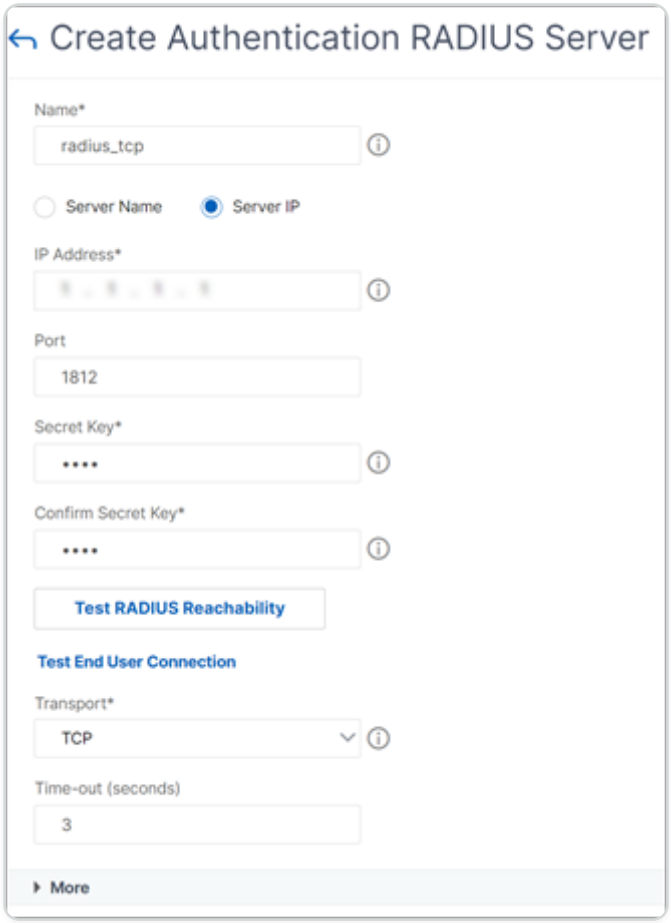
```
add authentication radiusAction RadAction -serverIP 1.1.1.1 -radkey 123
-transport TCP
```

Configure RADIUS over TCP by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > RADIUS**.
2. Select an existing server or create a server.

   For details on creating a server, see To configure a RADIUS server by using the GUI.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



3. In **Transport**, select **TCP**.
4. Click **Create**.

Configure RADIUS over TLS by using the CLI

At the command prompt type:

```
add authentication radiusAction <name> [-serverIP] [-serverPort ] [-
transport <transport>] [-targetLBVserver <string>]
```

Example

```
add authentication radiusAction RadAction -serverIP 1.1.1.1 -radkey 123
-transport TLS -targetLBVserver rad-lb
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

NOTE:

- Server name is not supported for TLS transport type.
- For the TLS transport type, configure a target load balancing virtual server of type TCP and bind a service of type SSL_TCP to this virtual server.
- The IP address and the port number configured for RADIUS action must match the IP address and port number of the configured target load balancing virtual server.

Configure RADIUS over TLS by using the GUI

1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > Servers**.
2. Select an existing server or create a server.

   For details about creating a server, see To configure a RADIUS server by using the GUI.
3. In **Transport**, select **TLS**.
4. In **Target Load Balancing Virtual Server**, select the virtual server. For details on creating a load balancing virtual server, see Creating a virtual server.

   NOTE:

   - Server name is not supported for TLS transport type.
   - For the TLS transport type, configure a target load balancing virtual server of type TCP and bind a service of type SSL_TCP to this virtual server.
   - The IP address and the port number configured for RADIUS action must match the IP address and port number of the configured target load balancing virtual server.
5. Click **Create.**

TACACS authentication

TACACS authentication policy authenticates to an external Terminal Access Controller Access-Control System (TACACS) authentication server. After a user authenticates to a TACACS server, the NetScaler connects to the same TACACS server for all subsequent authorizations. When a primary TACACS server is unavailable, this feature prevents any delay while NetScaler waits for

© 1997–2026 Citrix Systems, Inc. All rights reserved.

the first TACACS server to time out. It happens before resending the authorization request to the second TACACS server.

NOTE:

TACACS authorization server does not support commands whose string length exceeds 255 characters.

Workaround: Use local authorization instead of a TACACS authorization server.
When authenticating through a TACACS server, authentication, authorization, and auditing traffic management logs only successfully runs TACACS commands. It prevents the logs from displaying TACACS commands entered by unauthorized users.

Starting from NetScaler 12.0 Build 57.x, the Terminal Access Controller Access-Control System (TACACS) is not blocking the authentication, authorization, and auditing daemon while sending the TACACS request. This change allows LDAP and RADIUS authentication to proceed with the request. The TACACS authentication request resumes once the TACACS server acknowledges the TACACS request.

IMPORTANT:

- Citrix® recommends that you do not modify any TACACS-related configurations when you run a “clear ns config” command.
- TACACS related configuration related to advanced policies is cleared and reapplied when the “RBAconfig” parameter is set to NO in the “clear ns config” command for advanced policy.

Name-value attribute support for TACACS authentication

You can now configure TACACS authentication attributes with a unique name along with values. The names are configured in the TACACS action parameter and the values are obtained by querying for the names. By specifying the name attribute value, admins can easily search for the attribute value associated with the attribute name. Also, admins no longer have to remember the attribute by its value alone.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT

- In the tacacsAction command, you can configure a maximum of 64 attributes separated by comma with a total size less than 2048 bytes.

To configure the name-value attributes by using the CLI

At the command prompt, type:

```
add authentication tacacsAction <name> [-Attributes <string>]
```

Example:

```
add authentication tacacsAction tacacsAct1 -attributes
“mail,sn,userprincipalName”
```

To add an authentication action by using the CLI

If you do not use LOCAL authentication, you need to add an explicit authentication action. At the command prompt, type the following command:

```
add authentication tacacsAction <name> -serverip <IP> [-serverPort <port>]
[-authTimeout <positive_integer>][ ... ]
```

Example

```
add authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65
-serverport 1812                    -authtimeout 15 -tacacsSecret
"minotaur" -authorization OFF -accounting ON -auditFailedCmds OFF
-defaultAuthenticationGroup "users"
```

To configure an authentication action by using the CLI

To configure an existing authentication action, at the command prompt, type the following command:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
set authentication tacacsAction <name> -serverip <IP> [-serverPort <port>]
[-authTimeout <positive_integer>][ ... ]
```

Example

```
> set authentication tacacsaction Authn-Act-1 -serverip 10.218.24.65
-serverport 1812                    -authtimeout 15 -tacacsSecret
"minotaur" -authorization OFF -accounting ON -auditFailedCmds OFF
-defaultAuthenticationGroup "users"    Done
```

To remove an authentication action by using the CLI

To remove an existing RADIUS action, at the command prompt, type the following command:

```
rm authentication radiusAction <name>
```

Example

```
rm authentication tacacsaction Authn-Act-1
```

To configure a TACACS server by using the GUI

NOTE

In the GUI, the term server is used instead of action, but refers to the same task.

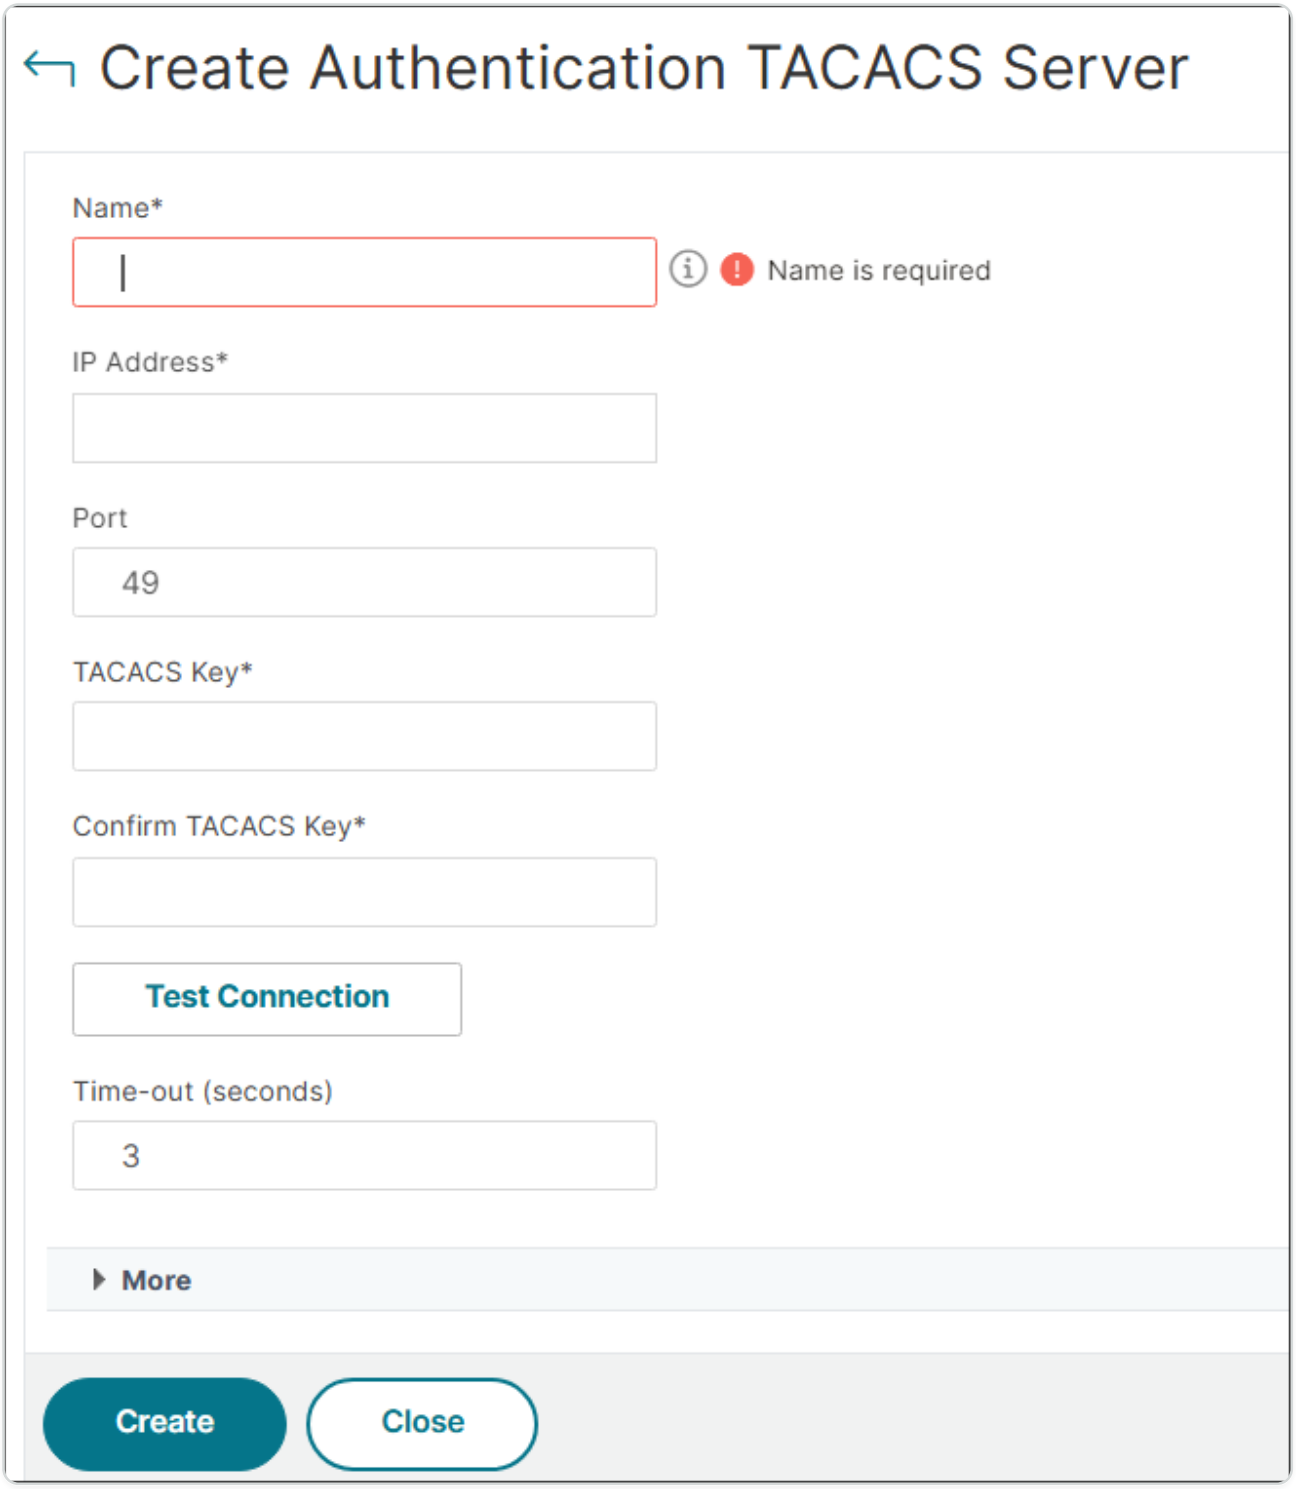
1. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies > Actions > TACACS**.
2. Click **Add** to create a TACACS server. To modify an existing TACACS server, select the server, and then click **Edit**.
3. In the **Create Authentication TACACS Server** page, type or select values for the following parameters.
   - **Name:** Name of the TACACS profile. The maximum length is 127 characters.
   - **IP Address:** IP address assigned to the TACACS server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Port:** Port number on which the TACACS server listens for connections. The default value is 49.
- **TACACS Key:** Key shared between the TACACS server and NetScaler. The TACACS key is required for allowing NetScaler to communicate with the TACACS server. The maximum length is 63 characters.
- **Confirm TACACS Key:** Type the TACACS key a second time.
- **Time-out (seconds):** Number of seconds NetScaler waits for a response from the TACACS server. The default value is 3 and the minimum value is 1.
- **Authorization:** Select **ON** to use streaming authorization on the TACACS server.
- **Accounting:** Select **ON** to enable the TACACS server to accept the accounting messages.
- **Default Authentication Group:** Default group that is chosen when the authentication succeeds in addition to extracted groups.
- **Group Attribute Name:** TACACS group attribute name used for group extraction on the TACACS server.
- **Attributes:** List of attribute names separated by a comma, which must be fetched from TACACS server. The attribute name can be 127 bytes and the total length of this string must not be more than 2047 bytes. These attributes are stored as key-value pair in authentication, authorization, and auditing session.

4. Click **Create** or **OK**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



Client certificate authentication

Websites that contain sensitive content, such as online banking websites or websites with employee personal information, sometimes require client certificates for authentication. To configure authentication, authorization, and auditing to authenticate users based on client-side certificate attributes, you first enable client authentication on the traffic management virtual server and bind the root certificate to the authentication virtual server. Then, you implement one of two options. You can configure the default authentication type on the authentication virtual server as

© 1997–2026 Citrix Systems, Inc. All rights reserved.

CERT, or you can create a certificate action that defines what the NetScaler must do to authenticate users based on a client certificate. In either case, your authentication server must support CRLs. You configure the ADC to extract the user name from the **Subject:CN** field or another specified field in the client certificate.

When a user logs on to an authentication virtual server for which an authentication policy and a global cascade is not configured, the user name is extracted from the specified certificate field. The authentication succeeds if the required field is successfully extracted. The authentication fails if the user name extraction fails. It also fails if the user does not provide a valid certificate during the TLS handshake or if the submitted client certificate is marked as BAD during the TLS handshake. After validating the client certificate, the ADC presents a logon page to the user.

The following procedures assume that you have already created a functioning authentication, authorization, and auditing configuration, and therefore they explain only how to enable authentication by using client certificates. These procedures also assume that you have obtained your root certificate and client certificates and have placed them on the ADC in the /nsconfig/ssl directory.

Configure client certificate authentication

Configure client certificate parameters by using the GUI

1. Install a CA certificate and bind it to an authentication virtual server.

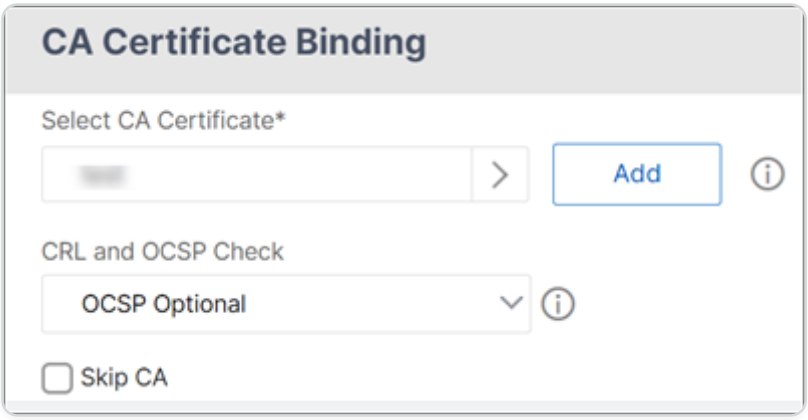
    a. Navigate to **Security > AAA - Application Traffic > Virtual Servers**.

    b. On the **Authentication Virtual Servers** page that appears, select the virtual server that you want to configure to handle client certificate authentication, and then click **Edit**.

    c. On the **Authentication Virtual Server** page, navigate to the **Certificate** section and click the right arrow ">" next to **CA Certificate**.

    d. On the **CA Certificate Binding** page, select a CA certificate, update the other required fields, and click **Bind**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

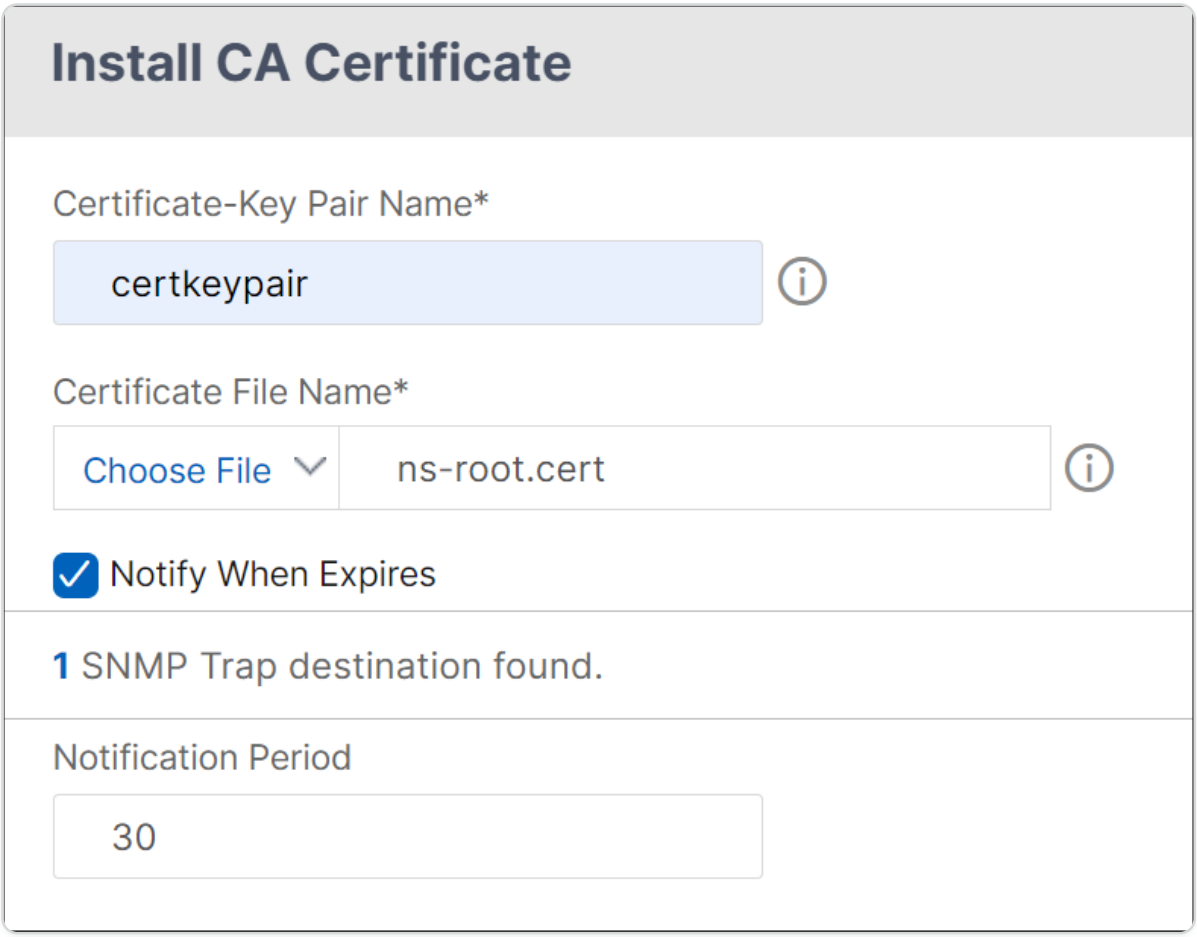


e. If a CA certificate is not available, then select **Add**.

f. On the **Install CA Certificate** page, update the following fields and click **Install** and then click **Close**.

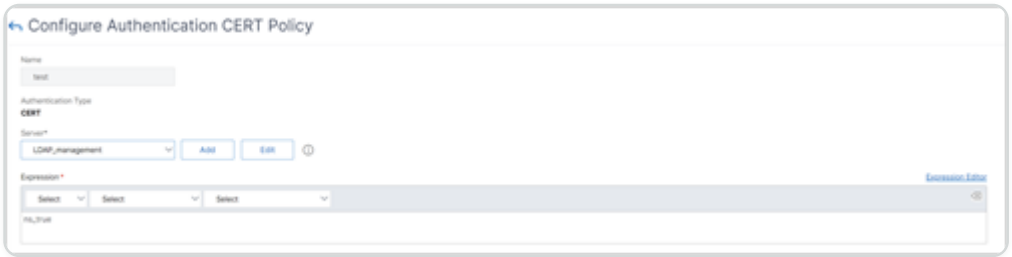
- **Certificate-Key Pair Name:** Name for the certificate and private-key pair.
- **Certificate File Name:** The name of the certificate file that is used to form the certificate-key pair. The certificate file must be present on the NetScaler's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. The default path is /nsconfig/ssl/.
- **Notification Period:** Number of days before certificate expiration at which NetScaler notifies the admin that the certificate is about to expire.
- **Notify When Expires:** Enable this option to receive an alert when the certificate is about to expire.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



g. Once the CA certificate is installed, go to the **CA Certificate Binding** page, bind it to an authentication virtual server.

2. Return to the **Security > AAA - Application Traffic > Virtual Servers** page.
3. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Basic Policies > CERT**.
4. Select the policy that you want to configure to handle client certificate authentication, and then click **Edit**.
5. On the **Configure Authentication CERT Policy** page, go to the **Server** drop-down list and select the virtual server that is configured to handle client certificate authentication.
6. Click **OK**.



© 1997–2026 Citrix Systems, Inc. All rights reserved.

Configure client certificate parameters by using the CLI

At the command prompt, type the following commands, in the order shown, to configure the certificate and verify the configuration:

```
add ssl certKey <certkeyName> -cert <certFile> -key <keyFile> -password
-inform <inform> -expiryMonitor <expiryMonitor> -notificationPeriod
<notificationPeriod>

bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority
<positive_integer>]

show ssl certKey [<certkeyName>]

set aaa parameter -defaultAuthType CERT

show aaa parameter

set aaa certParams -userNameField "Subject:CN"

show aaa certParams
```

Configure client certificate advanced authentication policies by using the GUI

1. Install a CA certificate and bind it to a certificate-key pair.

    a. Navigate to **Security > AAA - Application Traffic > Virtual Servers**.

    b. On the **Authentication Virtual Servers** page that appears, select the virtual server that you want to configure to handle client certificate authentication, and then click **Edit**.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

c. On the **Authentication Virtual Server** page, navigate to the **Certificate** section and click the right arrow ">" next to **CA Certificate**.

d. On the **CA Certificate Binding** page, select a CA certificate, update the other required fields, and click **Bind**.

e. If a CA certificate is not available, then select **Add**.

f. On the **Install Certificate** page, update the following fields and click **Install** and then click **Close**.

- **Certificate-Key Pair Name:** Name for the certificate and private-key pair
- **Certificate File Name:** The name of the certificate file that is used to form the certificate-key pair. The certificate file must be present on the NetScaler's hard-disk drive or solid-state drive. Storing a certificate in any location other than the default might cause inconsistency in a high availability setup. The default path is /nsconfig/ssl/.
- **Notification Period:** Number of days before certificate expiration at which NetScaler notifies the admin that the certificate is about to expire.
- **Notify When Expires:** Enable this option to receive an alert when the certificate is about to expire.

g. Once the CA certificate is installed, go to the **CA Certificate Binding** page and repeat step 4.

2. Return to the **Security > AAA - Application Traffic > Virtual Servers** page.

> **NOTE:**
>
> If you have imported a valid CA certificate and server certificate for the virtual server you can skip **steps 1 and 2**.

3. Navigate to **Security > AAA - Application Traffic > Policies > Authentication > Advanced Policies**, and then select **Policy**.
4. On the **Authentication Policies** page, do one of the following:

- To create a policy, click **Add**.
- To modify an existing policy, select the policy, and then click **Edit**.

5. On the **Create Authentication Policy** or **Configure Authentication Policy** page, type or select values for the parameters.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Name:** Policy name. You cannot change the name of a previously configured policy.
- **Action Type:** Type of the authentication action.
- **Action:** Name of the authentication action to be performed if the policy matches. You can choose an existing authentication action, or click **Add** and create an action.
- **Expression:** The rule that selects the connections to which you want to apply the action that you specified. The rule can be simple ("true" selects all traffic) or complex. You enter expressions by first choosing the type of expression in the leftmost drop-down list beneath the Expression window, and then by typing your expression directly into the expression text area, or by clicking **Add** to open the **Add Expression** dialog box and using the drop-down lists in it to define your expression.
- **Log Action:** The name of the audit action to use when an authentication request matches this policy. You can choose an existing audit action, or click **Add** to create an action.
- **Comment:** You can type a comment that describes the type of traffic that this authentication policy applies to. This field is optional.

6. Click **Create** or **OK**, and then click **Close**.

Client certificate pass-through

The NetScaler can now be configured to pass client certificates through to protected applications that require client certificates for user authentication. The ADC first authenticates the user, then inserts the client certificate into the request and sends it to the application. This feature is configured by adding appropriate SSL policies.

The exact behavior of this feature when a user presents a client certificate depends upon the configuration of the VPN virtual server.

- If the VPN virtual server is configured to accept client certificates but not require them, the ADC inserts the certificate into the request and then forwards the request to the protected application.
- If the VPN virtual server has client certificate authentication disabled, the ADC renegotiatiates the authentication protocol and reauthenticates the user before it inserts the client certificate in the header and forwards the request to the protected application.
- If the VPN virtual server is configured to require client certificate authentication, the ADC uses the client certificate to authenticate the user, then inserts the certificate in the header and forwards the request to the protected application.

In all of these cases, you configure the client certificate pass-through as follows.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Create and configure client certificate pass-through by using the CLI

At the command prompt, type the following commands:

```
add vpn vserver <name> SSL <IP> 443
```

For **name**, substitute a name for the virtual server. The name must contain from one to 127 ASCII characters, beginning with a letter or underscore (_), and containing only letters, numbers, and the underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. For `<IP>`, substitute the IP address assigned to the virtual server.

```
set ssl vserver <name> -clientAuth ENABLED -clientCert <clientcert>
```

For `<name>`, substitute the name of the virtual server that you created. For `<clientCert>`, substitute one of the following values:

- disabled—disables client certificate authentication on the VPN virtual server.
- mandatory—configures the VPN virtual server to require client certificates to authenticate.
- optional—configures the VPN virtual server to allow client certificate authentication, but not to require it.

```
bind vpn vserver <name> -policy local
```

For `<name>`, replace the name of the VPN virtual server that you created.

```
bind vpn vserver <name> -policy cert
```

For `<name>`, substitute the name of the VPN virtual server that you created.

```
bind ssl vserver <name> -certkeyName <certkeyname>
```

For `<name>`, substitute the name of the virtual server that you created. For `<certkeyName>`, substitute the client certificate key.

```
bind ssl vserver <name> -certkeyName <cacertkeyname> -CA -ocspCheck
Optional
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

For `<name>`, substitute the name of the virtual server that you created. For `<cacertkeyName>`, substitute the CA certificate key.

```
add ssl action <actname> -clientCert ENABLED -certHeader CLIENT-CERT
```

For `<actname>`, substitute a name for the SSL action.

```
add ssl policy <polname> -rule true -action <actname>
```

For `<polname>`, substitute a name for your new SSL policy. For `<actname>`, substitute the name of the SSL action that you created.

```
bind ssl vserver <name> -policyName <polname> -priority 10
```

For `<name>`, replace the name of the VPN virtual server.

Example

```
add vpn vserver vs-certpassthru SSL 10.121.250.75 443

set ssl vserver vs-certpassthru -clientAuth ENABLED -clientCert optional

bind vpn vserver vs-certpassthru -policy local

bind vpn vserver vs-certpassthru -policy cert

bind ssl vserver vs-certpassthru -certkeyName mycertKey

bind ssl vserver vs-certpassthru -certkeyName mycertKey -CA -ocspCheck
Optional

add ssl action act-certpassthru -clientCert ENABLED -certHeader CLIENT-
CERT

add ssl policy pol-certpassthru -rule true -action act-certpassthru

bind ssl vserver vs-certpassthru -policyName pol-certpassthru -priority 10
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Negotiate authentication

As with other types of authentication policies, a Negotiate authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy.

In addition to standard authentication functions, the Negotiate Action command can now extract user information from a keytab file instead of requiring you to enter that information manually. If a keytab has more than one SPN, authentication, authorization, and auditing selects the correct SPN. You can configure this feature at the command line, or by using the configuration utility.

NOTE

These instructions assume that you are already familiar with the LDAP protocol and have already configured your chosen LDAP authentication server.

To configure authentication, authorization, and auditing to extract user information from a keytab file by using the command line interface

At the command prompt, type the appropriate command:

```
add authentication negotiateAction <name> {-domain <string>} {-domainUser
<string>} {-domainUserPasswd } [-defaultAuthenticationGroup <string>] [-
keytab <string>] [-NTLMPath <string>]

set authentication negotiateAction <name> {-domain <string>} {-domainUser
<string>} {-domainUserPasswd} [-defaultAuthenticationGroup <string>] [-
keytab <string>] [-NTLMPath <string>]
```

`Parameter description`

- **name** - Name of the negotiate action to be used.
- **domain** - Domain name of the service principal that represnts NetScaler.
- **domainUser** - User name of the account that is mapped with NetScaler principal. This can be given along with domain and password when keytab file is not available. If username is given

© 1997–2026 Citrix Systems, Inc. All rights reserved.

along with keytab file, then that keytab file will be searched for this user's credentials. Maximum Length: 127

> **NOTE**
>
> The **domainUser** parameter is case-sensitive.

- **domainUserPasswd** - Password of the account that is mapped to the NetScaler principal.
- **defaultAuthenticationGroup** - This is the default group that is chosen when the authentication succeeds in addition to extracted groups. Maximum Length: 63
- **keytab** - The path to the keytab file that is used to decrypt kerberos tickets presented to NetScaler. If keytab is not available, domain/username/password can be specified in the negotiate action configuration. Maximum Length: 127
- **NTLMPath** - The path to the site that is enabled for NTLM authentication, including FQDN of the server. This is used when clients fallback to NTLM. Maximum Length: 127

To configure authentication, authorization, and auditing to extract user information from a keytab file by using the configuration utility

> **NOTE**
>
> In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to **Security > AAA - Application Traffic > Authentication > Advanced Policies > Actions > NEGOTIATE Actions**.
2. In the details pane, on the **Servers** tab, do one of the following:
   - If you want to create a new **Negotiate** action, click **Add**.
   - If you want to modify an existing **Negotiate** action, in the data pane select the action, and then click **Edit**.
3. If you are creating a new **Negotiate** action, in the **Name** text box, type a name for your new action. The name can be from one to 127 characters in length and can consist of upper- and lowercase letters, numbers, and the hyphen (-) and underscore (_) characters. If you are modifying an existing Negotiate action, skip this step. The name is read-only; you cannot change it.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

4. Under **Negotiate**, if the Use Keytab file check box is not already checked, check it.
5. In the Keytab file path text box, type the full path and filename of the keytab file that you want to use.
6. In the Default authentication group text box, type the authentication group that you want to set as default for this user.
7. Click **Create** or **OK** to save your changes.

Points to note when advanced encryptions is used for Kerberos authentication

- **Sample configuration when keytab is used:** add authentication negotiateAction neg_act_aes256 -keytab "/nsconfig/krb/lbvs_aes256.keytab"
- **Use the following command when keytab has multiple encryption types.** The command additionally captures domain user parameters: add authentication negotiateAction neg_act_keytab_all -keytab "/nsconfig/krb/lbvs_all.keytab" -domainUser "HTTP/lbvs.aaa.local"
- **Use the following commands when user credential are used:** add authentication negotiateAction neg_act_user -domain AAA.LOCAL -domainUser "HTTP/lbvs.aaa.local" -domainUserPasswd `<password>`
- Ensure that the correct **domainUser** information is provided. You can look for the user logon name in AD.

Web authentication

Authentication, authorization, and auditing is now able to authenticate a user to a web server, providing the credentials that the web server requires in an HTTP request and analyzing the web server response to determine that user authentication was successful. As with other types of authentication policies, a Web authentication policy is comprised of an expression and an action. After creating an authentication policy, you bind it to an authentication virtual server and assign a priority to it. When binding it, you also designate it as either a primary or a secondary policy.

To set up web-based authentication with a specific web server, first you create a web authentication action. Since authentication to web servers does not use a rigid format, you must specify exactly which information the web server requires and in which format when creating the action. To do this, you create an expression in NetScaler appliance Advanced policy that contains the following items:

- **Server IP**—The IP address of the authentication Web server.
- **Server Port**—The port of the authentication Web server.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

- **Authentication Rule**—An expression in NetScaler appliance Advanced policy that contains the user's credentials in the format that the Web server expects.
- **Scheme**—HTTP (for unencrypted web authentication) or HTTPS (for encrypted web authentication).
- **Success Rule**—An expression in NetScaler appliance Advanced policy that matches the web server response string that signifies that the user authenticated successfully.

For all other parameters, follow the normal rules for the add authentication action command.

Next you create a policy associated with that action. The policy is similar to an LDAP policy, and like LDAP policies uses NetScaler appliance syntax.

NOTE

These instructions assume that you are already familiar with the authentication requirements of the web server(s) to which you want to authenticate, and have already configured the web authentication server.

To configure a Web authentication action by using the command line interface

To create a web authentication action at the command line, at the command line type the following command:

```
add authentication webAuthAction <name> -serverIP <ip_addr|ipv6_addr|*>
-serverPort <port|*> [-fullReqExpr <string>] -scheme ( http | https )
-successRule <expression> [-defaultAuthenticationGroup <string>][-
Attribute1 <string>][-Attribute2 <string>] [-Attribute3 <string>][-
Attribute4 <string>] [-Attribute5 <string>][-Attribute6 <string>] [-
Attribute7 <string>][-Attribute8 <string>] [-Attribute9 <string>][-
Attribute10 <string>] [-Attribute11 <string>][-Attribute12 <string>] [-
Attribute13 <string>][-Attribute14 <string>] [-Attribute15 <string>][-
Attribute16 <string>]
```

Example

```
add policy expression post_data "\"username=\" +
http.REQ.BODY(1000).SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"login=\").BEFORE
_STR(\"&\") + \"&passwort=\" +
http.REQ.BODY(1000).SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"passwd=\")"
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add policy expression length_post_data "(\"username= \" +
http.REQ.BODY(1000).SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"login=\").BEFORE
_STR(\"&\") + \"passwort=\" +
http.REQ.BODY(1000).SET_TEXT_MODE(IGNORECASE).AFTER_STR(\"passwd=\")).leng
th"

add authentication webAuthAction webAuth_POST -serverIP 10.106.187.54
-serverPort 80 -fullReqExpr q{"POST /MyPHP/auth.php HTTP/" +
http.req.version.major + "." + http.req.version.major + "\r\nAccept:*/
*\r\nHost: 10.106.187.54\r\nReferer: http://10.106.187.54/MyPHP/
auth.php\r\nAccept-Language: en-US\r\nUser-Agent: Mozilla/5.0 (compatible;
MSIE 9.0; Windows NT 6.1; Trident/5.0)\r\nContent-Type: application/x-www-
form-urlencoded\r\n" + "Content-Length: " + length_post_data +
"\r\nConnection: Keep-Alive\r\n\r\n" + post_data} -scheme http
-successRule "http.res.status.eq(200)"
```

To configure a Web authentication action by using the configuration utility

NOTE

In the configuration utility, the term server is used instead of action, but refers to the same task.

1. Navigate to **Security > AAA - Application Traffic > Policies > LDAP**.
2. In the details pane, on the **Servers** tab, do one of the following:
   - If you want to create a new web authentication action, click **Add**.
   - If you want to modify an existing web authentication action, in the data pane select the action, and then click **Edit**.
3. If you are creating a new web authentication action, in the **Create Authentication Web** server dialog box, **Name** text box, type a name for the new web authentication action. The name can be from one to 127 characters in length, and can consist of upper- and lowercase letters,

© 1997–2026 Citrix Systems, Inc. All rights reserved.

numbers, and the hyphen (-) and underscore (_) characters. If you are modifying an existing web authentication action, skip this step. The name is read-only; you cannot change it.

4. In the **Web Server IP Address** text box, type the IPv4 or IPv6 IP address of the authentication web server. If the address is an IPv6 IP address, select the IPv6 check box first.
5. In the Port text box, type the port number on which the web server accepts connections.
6. Select **HTTP** or **HTTPS** in the **Protocol** drop-down list.
7. In the HTTP Request Expression text area, type a PCRE-format regular expression that creates the web server request that contains the user's credentials in the exact format expected by the authentication web server.
8. In the Expression to validate the Authentication text area, type a NetScaler appliance Advanced policy expression that describes the information in the web server response that indicates that user authentication was successful.
9. Fill out the remaining fields as described in the general authentication action documentation.
10. Click **OK**.

Configure SMS OTP for Web authentication

NetScaler can now be integrated with a third party SMS provider to provide an extra layer of authentication.

NetScaler appliance can be configured to send an OTP on the user’s mobile as a second factor of authentication. The appliance presents the user with a logon form to enter the OTP after successful AD login. It is only after the successful validation of SMS OTP authentication that the user is presented with the requested resource.

To achieve SMS OTP authentication, the NetScaler appliance relies on the following factors in the back end.

1. Authenticate the user using LDAP authentication and extract the user's mobile number.
2. Create OTP and store it in the NS variable. Configuring and using variables.
3. Send the OTP via WebAuth authentication method to the mobile number extracted from LDAP.
4. Validate the OTP.

Prerequisites

Enable features and add SNIP

Run the following commands to enable the features required for this configuration:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
enable ns feature LB SSL SSLVPN AAA

add ns ip <SNIP-IP> <subnet mask> -type SNIP
```

Configure OTP store

Admins must set up a database/store to save OTPs used for SMS authentication.

The recommended configuration range for the `expires` parameter (OTP expiration) is 30 to 180 seconds. Any value outside this range might result in a failed SMS OTP configuration and nFactor flow.

```
add ns variable otp_store -type "map(text(65),text(6),100000)"
-ifValueTooBig undef -ifNoValue undef -expires 60
```

Generate random OTP per user session

Use the following command to generate a 6-digit random OTP per user session and save it in the OTP store.

```
add ns assignment generate_otp -variable "$otp_store[AAA.USER.SESSIONID]"
-set ("000000" +
SYS.RANDOM.MUL(1000000).TYPECAST_UNSIGNED_LONG_AT.TYPECAST_TEXT_T).SUFFIX(
6)
```

Configure SMS OTP authentication with NetScaler

- Before you configure the SMS two factor authentication feature, you must have an LDAP authentication configured on a NetScaler appliance as first factor with authentication enabled. For instructions to configure LDAP authentication, see To configure LDAP authentication by using the configuration utility.
- Configure LDAP and extract the mobile number to be used for SMS OTP authentication.

Sample first factor configuration

Configure LDAP as the first factor for authentication.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
 add authentication ldapAction ldap_extraction_action -serverIP
<IP_Adress> -ldapBase OU=Sanity,dc=aaa,dc=local  -ldapBindDn
administrator@aaa.local -ldapBindDnPassword <password> -ldapLoginName
samaccountname -groupAttrName memberof -subAttributeName CN
-authentication disabled

 add authentication Policy ldap_extraction_policy -rule true -action
ldap_extraction_action
```

NOTE

Mobile number can be extracted using `AAA.USER.ATTRIBUTE(1)` and can be included while sending it to the back-end server.

Sample second factor configuration

Using the following sample configuration, an OTP that is to be sent to the end user is generated.

```
add authentication Policy set_otp -rule true -action generate_otp

add authentication policylabel set_otp_label -loginSchema LSCHEMA_INT

 bind authentication policylabel set_otp_label  -policyName set_otp
-priority 1

add authentication Policy cascade_noauth -rule true -action NO_AUTHN
```

Web authentication policy and action

Now, configure the web authentication action to send the OTP to any third party SMS sender along with the mobile number fetched from the LDAP policy.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Check the OTP and send the generated OTP to a third party SMS provider or any web server as configured below:

```
add policy expression otp_exp_post "\"Message: OTP is \" +
$otp_store[AAA.USER.SESSIONID] + \" for login into secure access  gateway.
Valid till EXPIRE_TIME. Do not share the OTP with anyone for security
reasons&Mobile:\" + AAA.USER.ATTRIBUTE(1)"

add authentication webAuthAction sms_post -serverIP <web_application_ip>
-serverPort 80 -fullReqExpr q{"POST /MyPHP/auth.php HTTP/" +
http.req.version.major + "." + http.req.version.major + "\r\nAccept:*/
*\r\nHost: <web_application_ip> \r\nContent-Length:100\r\n\r\n" +
otp_exp_post} -scheme http -successRule true

add authentication Policy post_wpp -rule true -action sms_post
```

Check the OTP

Add the following policy and policy label to check if the OTP exists for the user session:

```
add authentication policylabel check_otp_label -loginSchema LSCHEMA_INT

add authentication Policy check_otp -rule
"$otp_store.valueExists(AAA.USER.SESSIONID)" -action NO_AUTHN
```

OTP verification by comparing the user-provided value and the OTP store value

Run the following commands to verify the OTP by comparing the user-provided value and the OTP store value:

```
add authentication loginSchema onlypassword -authenticationSchema "/
nsconfig/loginschema/LoginSchema/OnlyPassword.xml"

add authentication policylabel otp_verify_label -loginSchema onlypassword
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add authentication Policy otp_verify -rule
"AAA.LOGIN.PASSWORD.EQ($otp_store[AAA.USER.SESSIONID])" -action NO_AUTHN
```

Bind the policy to the authentication policy label

```
bind authentication policylabel set_otp_label -policyName cascade_noauth
-priority 2 -gotoPriorityExpression NEXT -nextFactor check_otp_label

bind authentication policylabel check_otp_label -policyName post_wpp
-priority 1 -gotoPriorityExpression NEXT -nextFactor otp_verify_label

bind authentication policylabel otp_verify_label -policyName otp_verify
-priority 1 -gotoPriorityExpression NEXT
```

Create an authentication virtual server and a load balancing virtual server

```
 add authentication vserver avs SSL <ipadresss> 443

add ssl certKey aaa_local -cert aaatm_wild.cer -key aaatm_wild.key

bind ssl vserver avs -certkeyName aaa_local

bind authentication vserver avs -policy ldap_extraction_policy -priority 1
-nextFactor set_otp_label -gotoPriorityExpression NEXT

add lb vserver lb HTTP <ip_adresss> 80 -persistenceType NONE -cltTimeout
180 -AuthenticationHost <auth_server> -Authentication ON
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
add service svc <Ip_adresss> HTTP 80

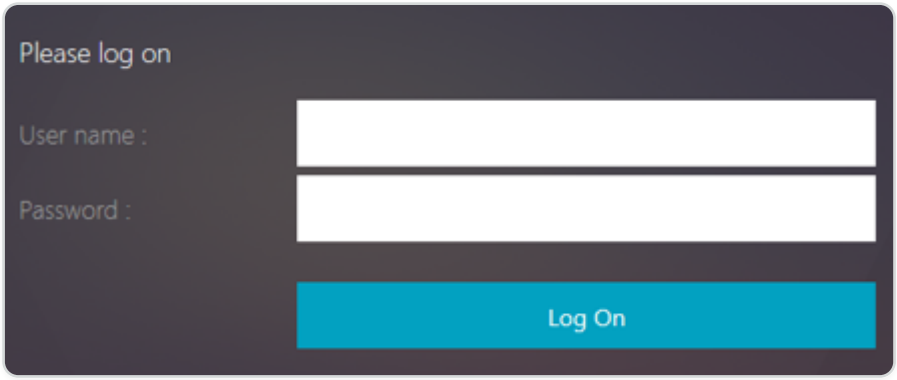
bind lb vserver lb svc
```

NOTE:

The policy for cascading authentication is added to enable reliable and continuous authentication for the end users. If the current factor fails, the next factor is evaluated such that there is no impact on the user experience.

Forms based authentication

With Forms based authentication, a logon form is presented to the end-user. This type of authentication form supports both multifactor (nFactor) authentication and Classic authentication.



Ensure the following for the Forms based authentication to work:

- The load balancing virtual server must have authentication turned **ON**.
- ‘authenticationHost’ parameter must be specified to which the user must be redirected for authentication. The command for configuring the same is as follows:

  ```
  set lb vs lb1 -authentication on –authenticationhost aaavs-ip/fqdn
  ```

- Form based authentication is compatible with browser that supports HTML

The following steps walk through how the Forms based authentication works:

© 1997–2026 Citrix Systems, Inc. All rights reserved.

1. The client (browser) sends a GET request for a URL on the TM (load balancing/CS) virtual server.
2. The TM virtual server determines that the client has not been authenticated, and sends an HTTP 302 response to the client. The response contains a hidden script that causes the client to issue a GET request for /cgi/tm to the authentication virtual server.
3. The client sends GET /cgi/tm containing the target URL to the authentication virtual server.
4. The authentication virtual server sends out a redirect to the login page.
5. The user sends out its credentials to the authentication virtual server with a POST / doAuthentication.do. Authentication is done by the authentication virtual server.
6. If the credentials are correct, the authentication virtual server sends an HTTP 302 response to the cgi/selfauth url on the load balancing server with a one time token (OTP).
7. The load balancing server sends HTTP 302 to the client.
8. The client sends a GET request for their initial URL target URL along with a 32 byte cookie.

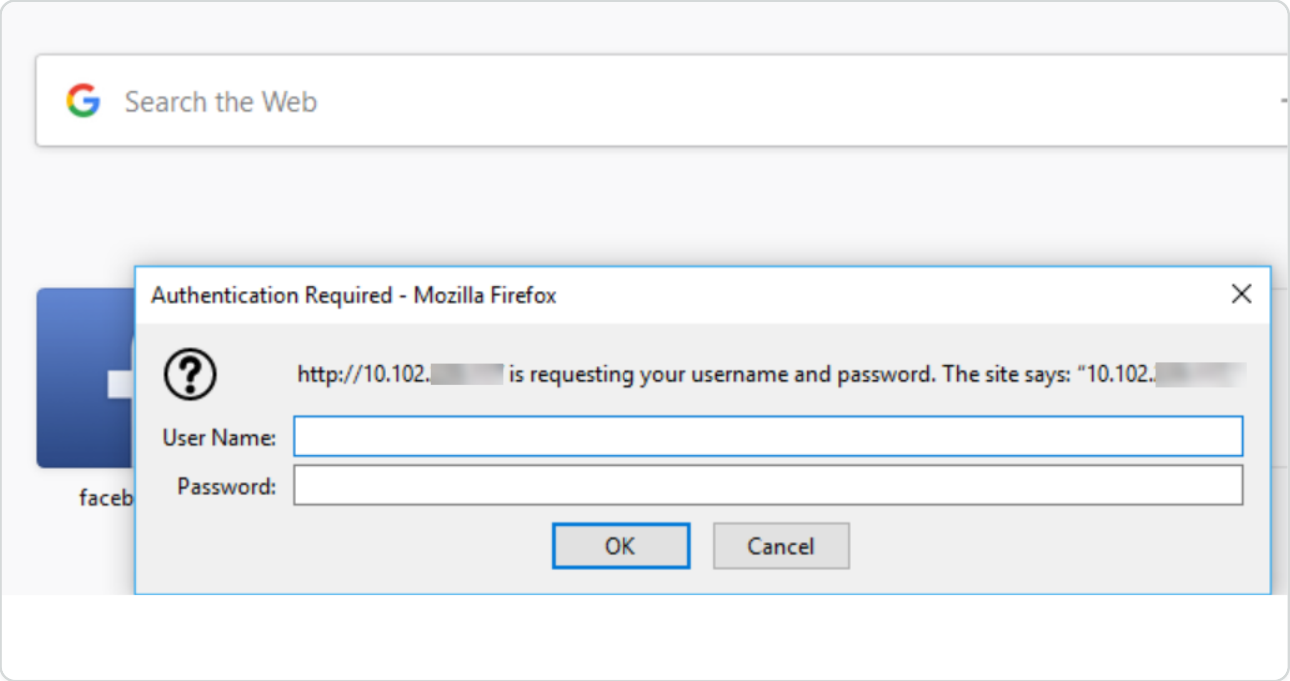
401 based authentication

With 401 based Authentication, the NetScaler appliance presents a pop-up dialog box to the end user.



Form based AAA-TM works on the redirect messages. Some applications do not support redirects, in such cases the 401 authentication enabled AAA-TM is used.

Enable the following parameters for 401 Authentication AAA-TM to work.

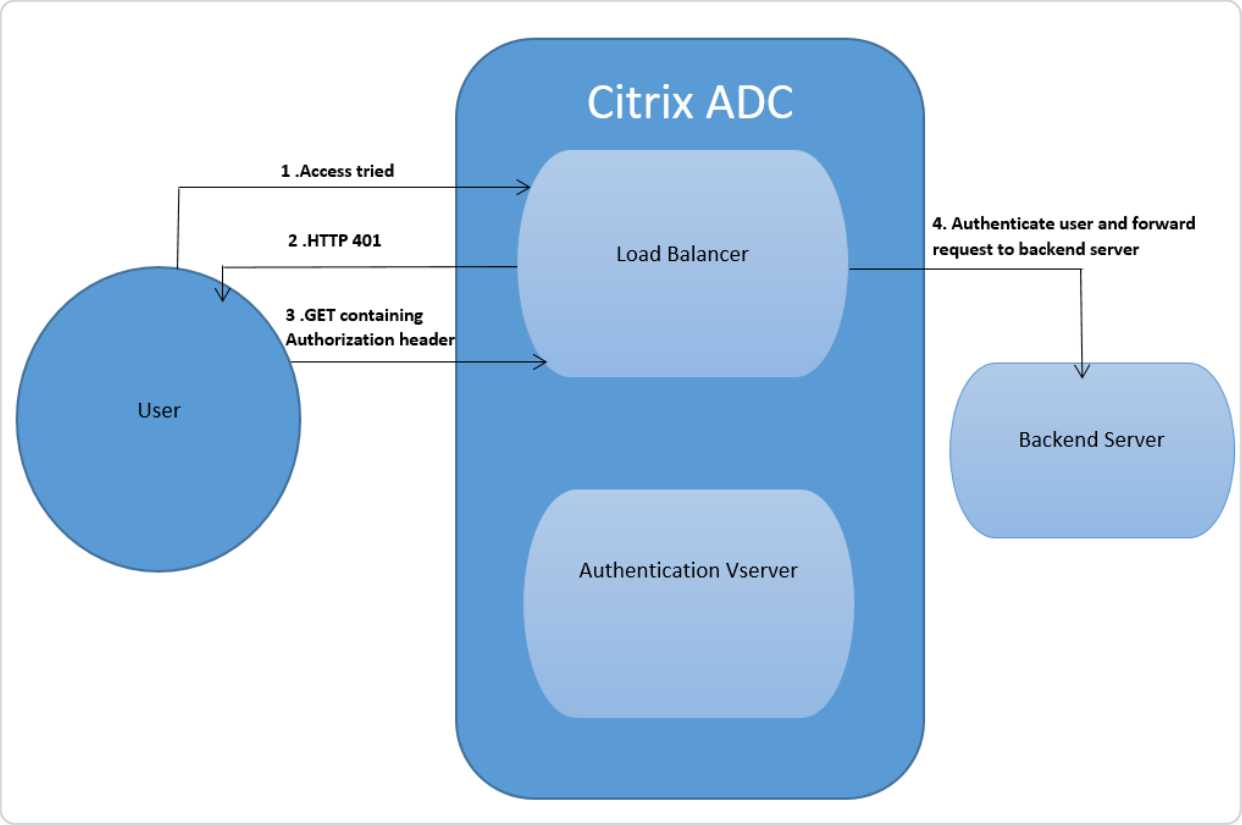
- 'authnVsName' parameter value for the load balancing virtual server must be the name of the authentication virtual server to be used to authenticate users.
- 'authn401' parameter must be enabled. The command for configuring the same is as follows:

```
set lb vs lb1 –authn401 on –authnvsName &lt;aaavs-name>
```

The following steps walk through how the 401 Authentication works:

1. User tries to access a particular URL using the load balancing virtual server.
2. The load balancing virtual server sends a 401 HTTP response back to the user indicating that authentication is required for the access.
3. The user sends its credentials to the load balancing virtual server in the authorization header.
4. The load balancing virtual server authenticates the user and then connects the user to the back end servers.

© 1997–2026 Citrix Systems, Inc. All rights reserved.



IMPORTANT:

For a load balancing virtual server with 401 authentication ON, several authentication and authorization sessions might be created for the same user in a short time. This configuration might lead to a spike in the memory. You can apply the following configuration on the NetScaler appliance to debug and identify the end client application.

```
set syslogparams -userDefinedAuditlog yes

add audit messageaction 401_log_act INFORMATIONAL '"LB-401 accessed: User:
<" + AAA.USER.NAME + "> SessionID <"+ AAA.USER.SESSIONID + "> Client :<" +
CLIENT.IP.SRC + "> accessed URL: <" + HTTP.REQ.URL + ">"'

add rewritepolicy rewrite_401_log true NOREWRITE -logAction 401_log_act
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind lb vserver <lb_name> -policyName rewrite_401_log -priority 100 -type
reqUEST
```

re-Captcha configuration for nFactor authentication

NetScaler Gateway supports a new first-class action `captchaAction` that simplifies re-Captcha configuration. As re-Captcha is a first-class action, it can be a factor of its own. You can inject re-Captcha anywhere in the nFactor flow.

Previously, you had to write custom WebAuth policies with changes to the RfWebUI as well. With the introduction of `captchaAction`, you do not have to modify the JavaScript.

Starting from NetScaler release 14.1 build 47.x, Google re-Captcha v3 is also supported in nFactor authentication in addition to re-Captcha v2 that was supported previously. Google re-Captcha v3 offers an advanced authentication method that assesses login requests without requiring user interaction. It assigns a score between 0.0 and 1.0 to each request, with higher scores suggesting safer requests. NetScaler can then use this score to determine whether to authenticate the user or not.

Starting from NetScaler release 14.1 build 51.x, Google re-Captcha v3 support is included for the Enterprise console. Previously, re-Captcha v3 support was limited to the Admin console, which has a fixed limit on the number of requests it can handle. In contrast, the Enterprise console allows for an increased request limit based on the subscription plan.

NetScaler currently supports the following re-Captcha configurations:

- re-Captcha v2 for Admin console
- re-Captcha v3 for Admin console
- re-Captcha v3 for Enterprise console

IMPORTANT:

If re-Captcha is used along with the user name or password fields in the schema, the **Log On** button is disabled until re-Captcha is met.

re-Captcha configuration

re-Captcha configuration involves two parts.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

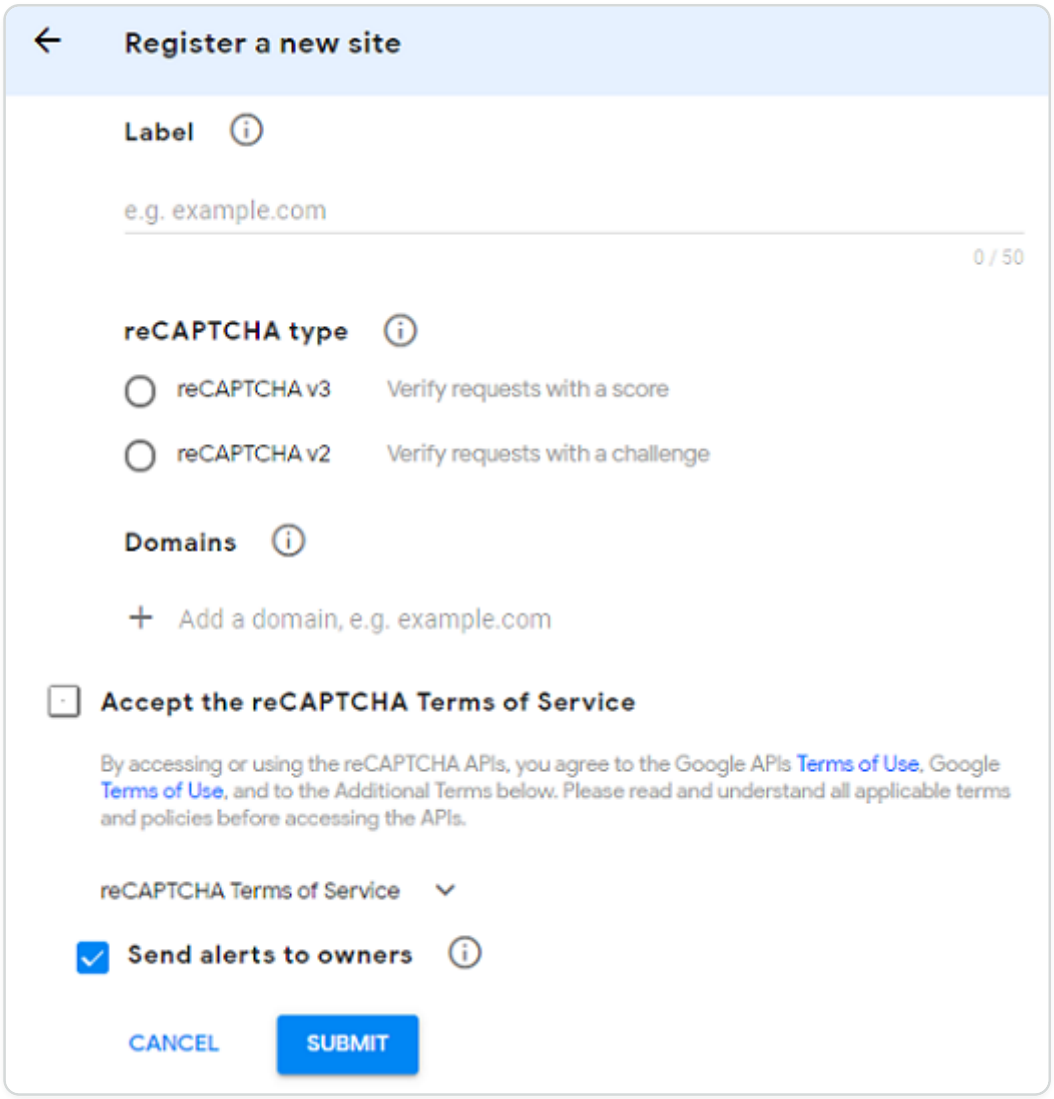
1. Configuration on Google for registering re-Captcha.
2. Configuration on NetScaler to use re-Captcha as part of the login flow.

re-Captcha configuration on Google

re-Captcha configuration for Admin Console (re-Captcha v2 and v3)

Register a domain for re-Captcha at `<https://www.google.com/recaptcha/admin#llist>`.

1. When you navigate to this page, the following screen appears.

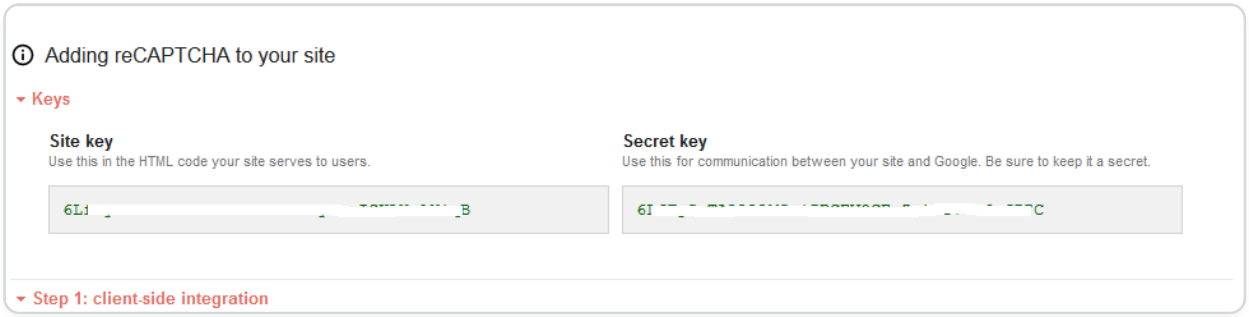


NOTE

For NetScaler release 14.1 build 47.x and later, select either **reCAPTCHA v2** or **reCAPTCHA v3** as required. Previous releases support **reCAPTCHA v2** only.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

2. After a domain is registered, the “SiteKey” and “SecretKey” are displayed. Note the displayed “SiteKey” and “SecretKey”.



NOTE

The “SiteKey” and “SecretKey” are grayed out for security reasons. “SecretKey” must be kept safe.

re-Captcha configuration for Enterprise Console (re-Captcha v3)

1. Sign in to `<https://console.cloud.google.com/>` by using a gmail account and create a project.
2. Go to `<https://console.cloud.google.com/security/recaptcha>` and create the site key. Note the created site key. For more information, see the Google re-Captcha document.
3. Go to `<https://console.cloud.google.com/apis/>` and create an API key. Note the created API key. For more information, see the Google re-Captcha document.
4. Go to `<https://console.cloud.google.com/security/recaptcha>` and copy the server URL from the assessment API (copy till the term "assessments"). Save the copied server URL.

   For example, if the assessment API is "https://recaptchaenterprise.googleapis.com/v1/projects/tactile-reason-455709-p6/assessments?key=API_KEY", you must copy the portion up to "assessments", which is "https://recaptchaenterprise.googleapis.com/v1/projects/tactile-reason-455709-p6/assessments". This extracted URL is used as the server URL in the `captchaAction` command.

re-Captcha configuration on NetScaler

The re-Captcha configuration on NetScaler can be divided into three parts:

- Display re-Captcha screen
- Post the re-Captcha response to the Google server
- Configure LDAP as the second factor for user logon

Display re-Captcha screen

The login form customization is done through the following login schemas:

- `SingleAuthCaptcha.xml` for re-Captcha v2 for Admin console
- `SingleAuthCaptchav3.xml` for re-Captcha v3 for Admin console
- `SingleAuthReCaptchav3Enterprise.xml` for re-Captcha v3 for Enterprise console

The customization is specified in the authentication virtual server and is sent to the UI for rendering the login form. The built-in login schema is in the `/nsconfig/loginSchema/LoginSchema` directory on NetScaler.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

IMPORTANT

- The login schema can be used when LDAP is configured as the second factor.
- You can customize the existing schema based on your use case. For example, you can modify it to include only the re-Captcha factor (without user name or password) or dual authentication with re-Captcha.
- If any custom modifications are done or the file is renamed, we recommend copying all the loginSchemas from the `/nsconfig/loginschema/LoginSchema` directory to the parent directory, `/nsconfig/loginschema`.

To configure display of re-Captcha by using the CLI

re-Captcha v2:

```
add authentication loginSchema singleauthcaptcha -authenticationSchema /
nsconfig/loginschema/SingleAuthCaptcha.xml

add authentication loginSchemaPolicy singleauthcaptcha -rule true -action
singleauthcaptcha

add authentication vserver auth SSL <IP> <Port>

add ssl certkey vserver-cert -cert <path-to-cert-file> -key <path-to-key-
file>

bind ssl vserver auth -certkey vserver-cert
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind authentication vserver auth -policy singleauthcaptcha -priority 5
-gotoPriorityExpression END
```

re-Captcha v3:

```
add authentication loginSchema singleauthcaptcha -authenticationSchema /
nsconfig/loginschema/SingleAuthCaptchav3.xml

add authentication loginSchemaPolicy singleauthcaptcha -rule true -action
singleauthcaptcha

add authentication vserver auth SSL <IP> <Port>

add ssl certkey vserver-cert -cert <path-to-cert-file> -key <path-to-key-
file>

bind ssl vserver auth -certkey vserver-cert

bind authentication vserver auth -policy singleauthcaptcha -priority 5
-gotoPriorityExpression END
```

In the preceding command, use the following login schemas for `<login_schema>` parameter:

- `SingleAuthCaptcha.xml` for re-Captcha v2 for Admin console
- `SingleAuthCaptchav3.xml` for re-Captcha v3 for Admin console
- `SingleAuthReCaptchav3Enterprise.xml` for re-Captcha v3 for Enterprise console

Post the re-Captcha response to the Google server

After you have configured the re-Captcha that must be displayed to the users, the admins add the configuration to the Google server to verify the re-Captcha response from the browser.

© 1997–2026 Citrix Systems, Inc. All rights reserved.

Prerequisites:

NetScaler contacts `<https://www.google.com/recaptcha/api/siteverify>` to validate the Captcha information. So, ensure that the site is reachable from NetScaler.

To verify if the Google site is reachable, run the following script:

```
curl -vvv https://www.google.com/recaptcha/api/siteverify
```

NetScaler contacts `<https://www.google.com/recaptcha/api/siteverify>` to validate the Captcha information.

To verify re-Captcha response from the browser for the Admin console

The “SiteKey” and “SecretKey” generated during registration of a domain in Google server must be used in the following CLI command.

re-Captcha v2:

```
add authentication captchaAction myrecaptcha -sitekey <sitekey-copied-
from-google> -secretkey <secretkey-from-google>

add authentication policy myrecaptcha -rule true -action myrecaptcha

bind authentication vserver auth -policy myrecaptcha -priority 1
```

re-Captcha v3:

```
add authentication captchaAction -siteKey <sitekey> -secretKey <secretKey>
-scoreThreshold <0 to 10>

add authentication policy myrecaptcha -rule true -action myrecaptcha
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
bind authentication vserver auth -policy myrecaptcha -priority 1
```

The default value of `scoreThreshold` is 5.

To verify re-Captcha response from the browser for the Enterprise console

The “site key”, “API key”, and “server URL” generated during registration of a domain in Google server must be used in the following CLI command:

```
add authentication captchaAction -siteKey <sitekey> -secretKey <APIkey>
-scoreThreshold<0 - 10> -serverurl <serverURL>

add authentication policy myrecaptcha -rule true -action myrecaptcha

bind authentication vserver auth -policy myrecaptcha -priority 1
```

The default value of `scoreThreshold` is 5.

Configure LDAP as the second factor for user logon

NOTE:

If LDAP authentication is not required, customize the following login schemas to remove the user name and password labels:

- `SingleAuthCaptcha.xml` for re-Captcha v2 for Admin console
- `SingleAuthCaptchav3.xml` for re-Captcha v3 for Admin console
- `SingleAuthReCaptchav3Enterprise.xml` for re-Captcha v3 for Enterprise console

The LDAP authentication happens after re-Captcha, if you add it as the second factor.

```
add authentication ldapAction ldap-new -serverIP x.x.x.x -serverPort 636
-ldapBase "cn=users,dc=aaatm,dc=com" -ldapBindDn adminuser@aaatm.com
-ldapBindDnPassword <password> -encrypted -encryptmethod ENCMTHD_3
```

© 1997–2026 Citrix Systems, Inc. All rights reserved.

```
-ldapLoginName sAMAccountName -groupAttrName memberof -subAttributeName CN
-secType SSL -passwdChange ENABLED -defaultAuthenticationGroup ldapGroup

add authenticationpolicy ldap-new -rule true -action ldap-new

add authentication policylabel second-factor

bind authentication policylabel second-factor -policy ldap-new -priority
10
